— DEATH OF MR. WILLIAM HARRIS.—Mr. William Harris, for the last forty years head gardener at Canwick Hall, Lincoln, died there on the 6th inst. at the ripe age of eighty years. The deceased, who had been in failing health for several months, was well known and highly respected in the district. He was a good gardener and a kind hearted man, ever ready to assist and encourage those under him. He enjoyed the entire confidence and regard of his employers, C. C. Sibthorp, Esq., F.R.H.S., and Mrs. Sibthorp. The funeral took place on Thursday last in Canwick churchyard. The deceased's successor at Canwick Hall is Mr. G. Green.

— APPLE GOLDEN NOBLE.—For cooking purposes this is a very fine variety, and the surprise is that it gets so rarely a passing reference. It is true that among the overwhelming number even of good varieties some must go unnoticed, but in a fairly large collection this, to my mind, deserves a place. It is a regular bearer, not so heavy perhaps as some; but in this there is an advantage, because one is spared the trouble of thinning, and the fruits are individually larger, and consequently better in every respect. It has a tempting appearance in the depth of colour in its skin, is perfectly distinct, and an excellent cooking Apple. With me it is a midwinter sort, but in some soils it would keep till later in the winter.—S.

— BOUVARDIA PROPAGATION.—In a short paper on Bouvardias recently, the writer refers to the method of propagation by roots. I saw it in operation, and some of its results the other day at Woodhatch. Mr. Salter took down from a shelf several pots that had been filled with root cuttings but a fortnight previously, and there were shoots half an inch long, and just peeping out of the soil. A piece or two lifted out showed the portions of roots to be from 1 inch to 1½ inch in length, and laid into the soil fairly close together, then covered with a thin surface of fine sandy material. The breaks were not from the apex of the root cutting, like we see from Seakale roots, but from a root bud very near the apex. The method seems to be a peculiarly simple one, and to bring in plants of compact habit and very floriferous.—A.

— EUCHARIS CULTURE.—I send herewith a photograph of the Eucharis as growing at Ghyllbank, St. Helens. It was taken on February 8th by an amateur. It does not show a crowd of blooms, as every one expanded was cut two days previously. I was much interested in Mr. Shalford's article in the *Journal of Horticulture* for March 2nd, although the methods that he recommends for growing them differ in several points from my system. I make no attempt at resting, either by cooler or drier treatment, and no manure or stimulant of any kind is used. They are repotted about every four years, but I think three years long enough. Of course by feeding they might be kept in good condition much longer. I also send photo of a single flower stem with a ten-petalled flower on it. It is the only bloom of abnormal form among about 2700 that I have cut since Christmas.—J. J., *Lancashire*. [The plants are, it is easy to see, admirably grown, and must be a pleasure to the cultivator. Unfortunately we are unable to reproduce the photographs that have been sent. The ten petalled flower is very attractive.]

— PLANTING FRUIT TREES.—Would that we could have the pleasure of reading a few more notes from the pen of our esteemed friend Mr. E. Luckhurst, for he is so thoroughly practical. I read with much interest his few fruit planting notes, under that eminently alliterative title of the three F's, and felt how thoroughly he was right in protesting against the old fallacy that southern raised trees—and the remark applies to trees and shrubs generally, as well as to fruit trees—are not hardy enough to plant northwards. So far from that being the case, they should be really hardier, seeing that under southern suns and on warmer soils both wood and roots get harder and more matured than can be the case in the north. But generally, I think, when ordering trees it is best not to go farther from home than is absolutely needful, because trees are often, over long journeys, some three or four days on the road, and if most carefully packed the roots get dried. I have often thought that failure on the part of amateurs after planting has largely resulted from not having taken the trouble to soak the roots in water some twenty-four hours before planting. Of course it often happens that the desired trees can only be obtained at some remote nursery, and it is specially desirable then the roots be well soaked before being planted. That nurserymen can plant in their nurseries so late as April and even May, of many things with so much success is largely due to the fact that the tree and shrub roots are so little exposed, and therefore are not dried ere being replanted.—PRACTICE.

METEOROLOGICAL OBSERVATIONS AT CHISWICK.

The week has been remarkable for clear, bright, spring-like weather. Once only has there been any rain—viz, on the evening of the 8th.

— FEBRUARY WEATHER AT HODSOCK PRIORY.—Mean temperature 40°. Maximum in the screen, 60° on the 10th; minimum in the screen, 19.9° on the 27th; minimum on the grass, 10.3° on the 28th. Number of frosts—in the shade, fourteen; on the grass, twenty-two. Sunshine seventy-one hours, or 26 per cent. of the possible duration. Difference from average, + 11. Rainfall, 1.47 inches. Difference from average, - 0.19. Rain fell on ten days. Rainfall from January 1st, 3.37 inches. Difference from average, - 0.09. Some stormy and showery weather from the 6th to the 15th, the rest of the month fine with a good many white frosts.—J. MALLENDER.

— FEBRUARY WEATHER AT DOWLAIS.—Rainfall, 6.04 inches, which fell on fourteen days; greatest fall, 1.31 inch on the 9th. Temperature: mean maximum, 46.285°; highest reading, 60° on the 19th; mean minimum, 30.142°; lowest reading, 16° on the 2nd. Below freezing point on seventeen days. The wind was in the E. and N.E. on seventeen days, and in the S.W. on five days. There were nine sunless days. A very stormy month until the 15th. Heavy snowstorms on the 4th, 5th, and 6th, fully 15 inches of snow falling on those dates; but the rain soon cleared it away. Thunderstorm, accompanied by heavy rain, on the 7th. A furious gale of wind on the 12th, and very heavy hailstorms on the 13th. Since the 25th we have had brilliant sun in the day with very sharp frosts at night, with no rainfall, and wind very quiet.—WM. MABBOTT.

— AUCUBA FERTILISATION.—Few things serve to show how subtle and volatile are pollen grains than do Aucubas, for fertilisation of flowers seems absolutely certain every year when a pollen-producing plant is thirty, forty, or even more yards away. It is possible that insects aid in this interesting result, but it almost seems as if the atmosphere was the chief agent. Certainly we have made a wonderful addition to the beauty of what was once an uninteresting race of shrubs by the introduction to gardens of the male form. I notice that while berries are showing abundantly in all directions, they seem to be later than usual in colouring. Perhaps the flowering period was last year later than usual, or the drought may have retarded fecundation. No doubt, also, fruiting has helped to dwarf them, as huge specimens are now seldom seen.—OBSERVER.

— ACACIA VERTICILLATA.—In large cool conservatories or greenhouses where space can be given for planting out Acacias, there are a number of species which could be grown with the greatest possible success that thrive indifferently if confined in pots. The above mentioned is one of this number, and it is difficult to conceive the beauty of specimens 15 to 20 feet high by 8 or 10 feet through, smothered with their pretty yellow blossoms. The flowers of this species are borne in short cylindrical racemes all over the previous year's growth. The colour varies on different plants from pale to bright yellow. It is extremely easy to cultivate, for if planted out in a well-drained border of half peat and half loam, there will be found to be little more trouble connected with it than keeping it well supplied with water and air while growing, and keeping a little dry during winter. By this treatment a splendid supply of flowers may be expected during February and March. It is a good plan to cut it back fairly hard after flowering, as young growths will then be made from 3 to 5 feet long, which, when covered with flowers, will be found useful where quantities of cut flowers are wanted.—D. K.

— MAIDENHEAD GARDENERS' SOCIETY.—At the fortnightly meeting of this Society on the 23rd ult. Mr. Roberts of Ealing read a very interesting paper entitled, "A Chat on Exhibitions," and Mr. Stone, Maidenhead, read a paper "On Some of the Medical Uses of Herbs," which were very much appreciated by the members. Mr. Ingamells was in the chair. A vote of thanks was passed to each essayist. There was a large attendance, and several new members were enrolled.—W. M.

— NATIVE GUANO.—For some considerable time the Native Guano Company has favoured us early in each year with a pamphlet of letters testifying to the value of Native Guano for manurial purposes. The one sent this season embodies upwards of sixty pages, and contains testimonials from every part of the country. Some of the writers refer to certain specific crops, and others take a wider base and speak in general terms. There is throughout a striking consensus of opinion of the utility of the material, and after perusing them no one can be surprised at its popularity. The address of the Native Guano Co. is 29, New Bridge Street, Blackfriars.

— ERICAS HYEMALIS AND WILLMOREI.—It may be interesting to remark, *apropos* of the origin of the double forms of *Pelargonium* as mentioned in "The History of the *Pelargonium*" in the *Journal* (page 172), and relative to Willmore's Surprise, that those popular garden hybrid Heaths (*Ericas hyemalis* and *Willmorei*) were, I believe, raised by Mr. Willmore's gardener at Strawberry Vale, Edgbaston, and consequently controverting the inclusion of the latter in the *Index Kewensis* as a species. It would, however, be interesting to learn the real origin of the varieties in question, and I have myself made repeated inquiries, but without success, and now I fear their further history is buried in the past. Can any of the other correspondents of the *Journal* afford the required information?—W. G.

— PITTOSPORUM CRASSIFOLIUM.—A few plants of this New Zealand species will be found useful for the greenhouse in spring, as in addition to flowering freely during February and March it makes a good foliage plant to use among plants that have been forced into flower before foliage appears. It has a compact sturdy habit, and makes good sized plants in comparatively small pots. The leaves are 2 to 2½ inches long, obovate, deep glossy green on the upper surface, and covered with a thick white tomentum on the under side. The flowers are reddish purple and drooping. A figure of it is given in the "Bot. Mag.," t. 5978. In the south-western counties it is hardy, and about London it can be grown outside if given the protection of a wall.—W. D.

— READING GARDENERS' ASSOCIATION.—A very interesting lecture on "The Onion" was given by Mr. A. Dean of Kingston-on-Thames, on Monday evening, before the members of this Society, the President, Mr. C. B. Stevens, presiding over a good attendance of members. The classification of the Onion, its various divisions, and the different varieties, were treated in a very able manner, followed by many practical hints on the preparation of the ground, manuring, time of sowing, and a few remarks on the enemies of the Onion and their treatment, judging at shows, and the uses of this most useful vegetable. A discussion followed. A vote of thanks was accorded to Mr. Dean for his paper. The exhibits included some well kept specimens of Onions, splendid Freesias, and several vases of blooms of *Primula obconica*.

— GREAT SOIL MAKERS.—Glaciers were and are important agencies in soil making and distribution. Whenever the climatic conditions of a country are such that more snow and ice are formed in winter than melts in summer, this surplus must accumulate year by year. After a while this pile of ice and snow becomes so deep and heavy that a great pressure is exerted on the lower layers and the ice begins to flow from underneath. The additions on the top of the pile increase the weight and cause the flow to continue. This was precisely the condition of affairs over northern regions in earlier geologic times. This ice flow extended down over the northern portion of the United States as far as the Ohio river. As this ice flow advanced it ground up and pulverised everything in its path. In fact, it is claimed by some authorities that the great lakes were scooped out by this gigantic ice flow. When the ice sheet reached down into our warmer climate it began to thaw. As it thawed and receded vast quantities of soil, boulders and debris were deposited. The region over which this deposit took place is known as the "drift area," and the land over which it did not extend is known as the "driftless area." Drift soil is the most fertile soil that we know, because it is deep and composed of a large variety of elements, while the driftless soil has only the elements that are to be found in the underlying rocks, which in many cases are near the surface.—W. D. GIBBS (in "American Agriculturist.")

— FARMERS AND FRUIT CULTURE.—Certainly there is great need for improved methods of fruit culture on farms, for one seldom sees fruit trees and bushes doing other than existing in such places, and not cultivated. But then, how can it be otherwise unless the farmer himself is a gardener also, and will attend to his trees and bushes, or else he is in such affluent circumstances that he can afford to keep a practical gardener, and thus have all his garden well cared for as well as his trees. But it would be absurd to assume that an ordinary agricultural labourer could look after the garden properly, much less attend to the trees and bushes. Evidently farmers should have their sons taught gardening as well as agriculture, especially fruit culture. But if the sons prefer to be hunting, sporting, or otherwise wasting valuable hours, then there is no hope whatever that the agriculturist can ever develop into a satisfactory fruit grower. But under no circumstances would I advise the farmer embarking in fruit culture as a trading speculation, unless his proclivities were warmly in that direction. Such knowledge as may suffice to grow good field crops is of no use when fruit culture is concerned. To do that with success and profit a farmer must have long experience in the work, and that can only be obtained in fruit nurseries, in good private gardens, and in special fruit gardens. He must also have the widest knowledge of packing, selecting, selling, and all the essentials to marketing work. How is he to acquire all this knowledge consonant with acquiring a full knowledge of agriculture? But, after all, fruit culture for market is a distinct vocation, and is so much more prosperous and successful when undertaken by specialists who through long experience have learned to know what are all the essentials to that success, without which no such enterprise can be profitable.—A. D.

NOTES ON FORCING FIGS.

EARLIEST TREES IN POTS.

EARLY Violet and St. John's varieties that were started in gentle bottom heat in November are now beginning to take their last swelling of the fruit for ripening; and to insure flavour, also to prevent "spot," a drier condition of the atmosphere and a high temperature, with increased ventilation on fine days, is desirable. To check red spider it is advisable to paint the hot-water pipes with sulphur. The larger fruited varieties, however, have not the fruit sufficiently forward to admit of the relatively dry treatment without prejudice to their crops. Anything approaching dryness at the roots must be avoided, yet lessened supplies are needed than when the fruit is swelling. Brown Turkey, Pingo de Mel, and similar varieties should have good supplies of tepid liquid manure twice a week, and the top-dressings be replenished, lumpy manure absorbing moisture when the trees are syringed, and gives off genial vapour for some time afterwards. Syringe twice a day when fine, once only when the weather is dull, the second syringing being given in time for the foliage to become fairly dry before night. Maintain a night temperature of 65° when mild, 70° to 75° by day, and a heat ranging from 75° to 85° with sun. Stop and thin the side shoots, as Figs enjoy light, full exposure to sunshine, training terminals forward where space admits or there is need to preserve the symmetry, always guarding against overcrowding.

SUCCESSION HOUSES.

Trees in borders make very rapid growth, hence the necessity of frequent attention in stopping the shoots at the fifth or sixth leaf. As a well-developed spur, as such shoots are called, gives the best results in the second crop when a number of shoots appear together, they may all be removed but one, so as to cause it to be sturdy and fruitful. Train and regulate the terminals as required. The trees require liberal supplies of water through a good, but not heavy mulching of manure; or supply liquid manure. Syringe twice a day unless dull, when once suffices, or not that when the weather is close and moist, but damp the paths and walls occasionally, and again moisten the mulching when it becomes dry. This is better than keeping it constantly saturated. Ventilate freely in the early part of the day, but maintain a temperature of 75° to 85° from sun heat through the day, and close with a brisk heat and plenty of moisture about three o'clock in the afternoon. Maintain a night temperature of 60° to 65°, and 65° to 70° on dull days, with a little ventilation.

LATE HOUSES.

Figs ripen one crop in a season in unheated houses, but late varieties require fire heat to ripen the fruit well. Negro Largo is one of the best late Figs. The house must have a full exposure to the south. Well drained, narrow, inside borders are best. The growths should be trained about 16 inches from the glass. Prune the trees, and dress them with an insecticide, being careful not to injure the embryonic Figs or break the points of the shoots. Supply water so as to thoroughly moisten the soil, and keep the trees dormant as long as possible; but when they begin to grow afford generous treatment, admitting air soon, and closing early in the afternoon so as to husband the sun heat. Avoid, however, a close atmosphere, as that hinders the proper formation of the foliage, and too hasty treatment may cause the fruit to fall.

RAISING YOUNG TREES.

This is a good time to propagate young plants from cuttings. Select shoots from 5 to 6 inches in length, with a heel of last year's wood

attached, and remove all the eyes from the part to be inserted in the soil. This may consist of good fibrous loam with a sixth of old mortar rubbish incorporated. They root freely in a bottom heat of 75° to 80°. For general purposes Brown Turkey is the best variety, but Pingo de Mel is a very desirable one, giving good results in the first crop. For very early forcing Early Violet and St. John's are excellent varieties.—GROWER.

GROWING ZINNIAS.

PROCURE seed of double Zinnias from a reliable firm, sow it at the right time, and give the plants about half the attention required to prepare Zonal Pelargoniums for bedding; plant them in a well prepared bed by themselves, and they will repay the cultivator with a rich and continuous harvest of bloom, by the side of which Pelargoniums will be tame and carpet bedding flat. Not only so, he will be able to "cut and come again," for few flowers last so well when cut as Zinnias, and if arranged so as to take off their rather stiff formality they are very effective for dressing flower stands.

At first sight it seems surprising that plants of this nature are not more largely grown, but is it not a fact that many beautiful easily grown plants and flowers have often to give place to those which are much more difficult and expensive to grow, but which, in many cases, are far less effective and profitable? The reason is not far to seek, for it is often because they are easily managed that they are left to themselves until what should have been a grand display becomes an eyesore, such as a Zinnia, for instance, with a small solitary flower on the top of a thin nearly leafless stem, which requires a stake to prevent it falling.

I have tried every phase of bedding—carpet, subtropical, succulent, ribbon borders, and mixed beds, but although all have done well, none has been so much admired as a bed of Zinnias; indeed, although they were far less trouble and expense to prepare I had nothing to equal them either for use or beauty. The seeds were sown on a slight hotbed early in April, the plants were pricked off into a cold frame in May, and planted on a large circular bed 6 inches apart (they should have been 9 inches apart) in June, where from the first week in July they formed a rich mass containing many shades and colours of bloom.

For the guidance of beginners I will give more detailed instruction on the cultivation of Zinnias, which may be safely applied to many beautiful annuals. Those having frames or other means of protection should make a slight hotbed with leaves or well sweetened stable manure the first week in April. The frame may be placed on the bed as soon as made, and 6 inches of compost, consisting of equal parts of loam, leaf mould, and sand, laid over the bed inside the frame, and should be well pressed down. Draw drills 3 inches apart and 1 inch deep, in which the seeds should be thinly sown and covered with fine light soil sifted for the purpose. If each colour be kept separate and duly labelled it will be of great advantage, as then the colours can be more artistically arranged in their permanent quarters.

The light should be kept closed until the seedlings appear through the soil, when on every favourable opportunity they must have a little air until they are in rough leaf, after which on warm days remove the light, the object being to produce strong sturdy plants. Through April and May, however, we often have hot sunshine with cold winds. On no account must the light come off on such occasions, but give a little ventilation, or if very rough and cold keep the frame closed. Plenty of air will get under the glass to prevent injury, but if the sun be very hot a slight shade will be better than admitting the cold wind. Set the frame on a hard base, put in 2 inches of leaves and 9 inches of the following compost—three parts of loam, one part leaf mould, one part Mushroom bed refuse, and one part sand, thoroughly mixed and pressed down firmly. Carefully prick off the seedling plants into this frame 4 inches apart, giving a good watering with warm water through a rose can. Keep them close and shaded from sunshine for a few days, then admit a little air, gradually increasing it until the light can be removed through the day, which may be done in about fourteen days after pricking off. The last week in May the light should be left off day and night, always remembering what has been said about cold winds, for they sometimes pay us their unwelcome visits far into June.

The first or second week in June, according to the weather, the plants should be transferred to their flowering quarters, which to do them justice must be a well manured, deeply dug bed, but of course plants prepared as above will make a grand display in mixed beds or borders if not too much smothered by neighbours. Give the plants in the frame a good watering a few hours before lifting them; they will then carry clumps of earth, and may be transplanted without any check if carefully handled. Plant them 9 inches apart, arrange the colours according to taste, and give a good watering to settle the soil round the roots; the cultivator will then, in due time, be rewarded with a rich and continuous display of large flowers and a general effect such as is seldom produced by plants requiring a more troublesome and costly preparation. If 3 inches of cocoa-nut fibre refuse, or the sifted material of a spent Mushroom bed, be laid over the soil it will keep the roots cool and moist, save much watering, and benefit the plants considerably.

The following annuals may be grown to perfection if treated according to the above directions, only, being for the most part hardier, they may be planted out earlier, and the smaller growing ones closer together:—Asters, Ten-week-Stocks, Helichrysums, Salpiglossis, Petunias, Phlox Drummondii, and Portulacas, all of which will richly reward the cultivator if liberally treated.—R. J.

GREENHOUSE CLIMBERS.

No greenhouse or conservatory of any pretensions whatever can be said to be complete unless it is furnished with a good selection of climbers. To lofty structures especially they add a grace and elegance which is very pleasing where the selection has been made judiciously, only using such as are best adapted to the construction of the house. For instance, a plant of *Tacsonia Van Volxemi* or *Clematis indivisa lobata* would be entirely out of place in a low structure, but would be seen to advantage in a lofty house. In the following notes our aim is to help such as may be contemplating planting a few climbers, and who have a difficulty in deciding what to plant.

Sometimes it is desirable to cover the back wall of a greenhouse. We will therefore endeavour in the first place to mention one or two climbers which we have found answer this purpose admirably. But before enumerating varieties we would mention that in all cases where it is at all possible the best plan is to have prepared borders in which to insert the plants. They succeed so much better under this system and require a minimum of attention.

For a moderately high wall the Silver Wattle, *Acacia dealbata*, makes a beautiful covering. The foliage is neat and pretty, silvery grey in colour, and the bright yellow flowers are produced in profusion early in the spring. A light rich compost of fibrous loam, leaf mould, and sand made rather firm suits this Australian plant, which also delights in abundance of water at the roots. Pruning should be done immediately after flowering, and consists in cutting back long shoots and thinning out where crowded.

Then the Cherry Pie (*Heliotropium peruvianum*) succeeds on the back wall of the greenhouse where a maximum of light is obtained. In this position it will bloom perpetually, and there are few flowers which are more appreciated, especially by ladies, on account of the delicious perfume. The plants must annually be pruned in the month of February, cutting the preceding season's growths back to within one or two eyes of the main stem in the same manner in which Gooseberries are pruned. They will soon produce fresh growth, and in a short time completely cover the wall. The Heliotrope is not very particular as to soil; any fairly good light loam will suit it capitally. We have known baskets of flowers gathered throughout the summer and autumn from a single plant, and even in the dull winter months a fair amount have been got.

Cestrum elegans is another plant which is splendidly suited for back walls or pillars in the greenhouse. Although it is a native of Mexico it succeeds very well in a greenhouse temperature, and is one of those plants upon which at all seasons one can depend on finding at least a few flowers. The flowering season, however, is during summer, when it produces abundance of large cymes or clusters of reddish flowers, which hang like great pendants amidst the bright green foliage. This plant requires liberal treatment, a rich soil, and abundant supplies of liquid manure during its season of growth. Prune early in the year, cutting away all weak growth and shortening back others in such a way that the plant will be well furnished to the base with flower-producing growths. *Habrothamnus elegans* is another name by which it is known.

Amongst those which are adapted to training on the roof of the conservatory, perhaps *Lapagerias* stand unrivalled. The *Lapageria* is a native of Chili, whence it was introduced in the year 1847, and was named after a French Empress, Josephine Lapagerie. Perhaps few flowers are more admired than this, especially the white variety, which looks extremely chaste hanging amidst the dark green, leathery foliage. It should be accorded a slight shade during bright sunny weather, as the young leaves are liable to be burnt when fully exposed. After flowering, all exhausted growths should be removed to make room for the young shoots; but further than this, little pruning is needful. Equal parts of good fibrous peat and fibrous loam, with a free admixture of sharp sand and a quantity of broken bricks and chareoal, will be found a good rooting medium for this beautiful climber.

During the growing season water must be given unstintingly, and at no season should the soil be allowed to get dry, consequently the borders must be carefully and amply drained. When young shoots are pushing up from the base a constant watch must be kept, as snails are particularly fond of the tender points. The blooms last a long time in perfection, and the flowering period extends over months. The red and white varieties when allowed to intermix look very beautiful, the two colours making a chaste combination.

Tacsonia Van Volxemi is a very pretty and characteristic plant for draping the roofs of lofty houses. Its beautiful scarlet flowers have a graceful and refined appearance, hanging by the long slender foot-stalks. It is a rapid grower, and covers a large space in a very short time. The flowers are produced plentifully in the late summer and autumn. Then there is the *Bougainvillea*, another pretty greenhouse climber, which should find a place even in a small collection. The bracts are the principal feature, and these are very beautiful indeed, deep heliotrope or lilac in colour, and produced in lavish

abundance. No attempt must be made to train the *Bougainvillea* in any hard and fast way, but allow it to ramble freely, as under this style it produces its flowers more freely, and is also seen to greater advantage. Good turfy loam, with a little leaf mould and sand added, makes an excellent compost in which to plant it. Abundance of water, with frequent applications of manure during summer, tend to produce the best results. Keep drier during winter, and induce the plant to rest. In February prune hard in cutting away all weak growths and spurring others close in like Gooseberries.

Another very fine climber is *Clematis indivisa lobata*, a native of the Antipodes, which yields a profusion of starry snow-white flowers early in the spring. It is a rapid grower, and requires ample space to ramble. The flowers are considerably smaller than those of the well-known hardy varieties, but the immense quantities produced make up for any lack in size of the individual blossoms.

The foregoing do not by any means exhaust the list of greenhouse climbers, but in selecting them we have endeavoured to have as varied and as representative a choice, both in form and in colour, as we could.—ALEYN.

THUNBERGIA HARRISI.

No. "L. Row," *Thunbergia Harrisi* is not by any means of recent introduction, and it is probable that you have occasionally seen the plant not in flower, and consequently have not had your attention particularly drawn to it. It was introduced from the East Indies about forty-five years ago, and was some years ago accorded a first-class certificate by the Royal Horticultural Society when exhibited from the gardens of Lady Theodora Guest at Henstridge. The flowers (fig. 55) are large and very showy, being purplish blue with a pale yellow suffusion in the throat. They are freely produced in racemes, and are sufficiently beautiful to warrant the inclusion of at least one plant in every stove. It requires precisely similar treatment to other stove *Thunbergias*, and if well grown and kept free from insect pests, it will flower in the late summer and be sure of considerable admiration.

NOBLE-FOLIAGED PLANTS.

APART from Palms, with all the diversification of grace, elegance, or majesty characterising the great family, there are certain distinguished members of the vegetable kingdom which, by their power of imparting a tropical tone to our conservatories, hold a unique position among cultivated plants. Much depends, however, upon the adaptation of natural freedom to them in their artificial surroundings, for without such consideration it is possible to tame them into comparative insignificance. The conservatory as a show house—viz., a general repository absorbing such things from the glass department as tend to keep it gay—does not, in the formal arrangement of an heterogeneous gathering, lend itself to the effective display of our noble-foliaged plants. Their disposal for the best effect requires that more subtle and harmonious scheme in which no arrangement is apparent—in short, the reproduction in miniature of the handiwork of Nature in her happiest moods. In illustration, the thought arises, when viewing a photograph or picture of some pretty peep in sunnier lands, that could our conservatory be lifted, as one lifts a cap-glass, and popped down upon a bit of the best of what is felt to be so good, the ideal in this direction would be captured. There is something peculiarly graceful and fascinating in these choice bits of Nature when introduced to the homelier surroundings of a cooler clime, but it requires the co-operation of an artistic eye, with the gardening hand, to do them justice, to which pots and primness are fatal.

In brief, however, it is chiefly to the plants our subject pertains, although the development, rather than the curtailment, of their natural charms seems inseparably connected with conservatory culture. *Musa ensete*, if not strictly a tropical plant, holds a prominent place from its beauty of foliage, dignified habit, and amenity to culture. Unlike its first cousin, *M. Cavendishi*, the Chinese Banana, it does not produce suckers, hence this necessitates its reproduction by seeds. At first sight some little difficulty may appear to attend this method of propagation, for it is not easy to obtain the seeds, and when to hand they look more like freaks of Nature than the dormant germs of this noble foliaged plant. Late in the autumn of 1897 I was able to procure, through one of our home seed merchants, from the house of Vilmorin, of Paris, 100 seeds, which were at once put into a tin dish of well saturated Jadoo fibre, and placed direct on the hot-water pipes of a stove-house. In some six weeks vegetation commenced, and as the plants appeared they were transferred to thumb pots, the Jadoo fibre, enlivened by some sharp silver sand, still being used and repeated in succeeding shifts until 8-inch pots were necessary.

Thirty healthy plants in all were raised from the 100 seeds, and possibly a higher percentage would have shown had we persevered

with them, but the quantity obtained was more than sufficient for our requirements. One thing was noticed, however—viz., that the last plants taken from the seed pan were of low vitality, and remained weak and puny for some time. All are now, in less than eighteen months from sowing, strong healthy plants, 3 feet high, with stout stems, and having long since been root-bound are about to be transferred into oak tubs 16 inches deep by 16 inches across the top. These tubs, having been neatly covered with virgin cork, are intended for various vantage points of the rockwork in a large conservatory,

attaching itself to any bare bit of damp wall, similar in manner to *Ficus repens*. In its peculiar Aroid-like inflorescence and singularly striking fruit, springing erect through the large leathery leaves from horizontal stems, the *Monstera* is *par excellence* one of the handsomest, and probably the most interesting plant for the purpose of beautifying a warm conservatory.

Totally distinct in habit and appearance, yet equally handsome, is the *Papyrus*, a plant rarely seen outside of botanical collections. *Papyrus antiquorum* is indeed a plant worthy of place wherever the

FIG. 55.—THUNBERGIA HARRISI.

and the plants thus treated are readily adapted to temporary use in the dwelling house. Musas, it must be admitted, are not, in a sense, good house plants, but there is a charm in their fresh green noble foliage, heartily welcomed upon special occasions.

Monstera deliciosa, in its quaintly cut handsome foliage, interesting habit, and luscious fruit, has few rivals, and one wonders that it is so rarely met with. True it is a tropical plant, but nevertheless flourishes under semi-tropical treatment, and objects not to a minimum temperature of 50° during the dark days of winter. Planted well up in the rockwork attached to a back wall it enjoys the position if fairly warm and moist, and rambles away at its own sweet will, eventually

desire exists to give a tropical tone and that one touch of nature so often conspicuous by its absence from the conservatory. Enjoying, as it does, the humidity of stove treatment, it is not wholly exclusive in its requirements, for in one place within touch it has been successfully introduced into what was an orangery, now converted into a winter garden, where the desideratum of a minimum temperature of 50° is not always maintained during winter. Springing from an informal bed of rockwork, all but hidden by a natural growth of humbler things, this giant *Cyperus* appears to be particularly happy in the position. Given the presence of its element—water—in the form of a tiny pool or miniature bog, which is appropriate to its taste

as well as appearance, we have a happy illustration of the fitness of things to a purpose.

The fine-foliaged Anthuriums, not so often seen as of yore, permit of little laxity in the way of temperature. Strictly stove plants and fairly revelling in a kind of Sierra Leone heat and humidity, they require a tropical house to develop their beauty. Here, however, they are grand objects, more especially if planted in a rock-pocket upon some vantage point. There are few finer objects than a well-grown plant of the more recently introduced Anthurium Veitchi; and although the planting out process of so choice a plant may commend itself to few, the cork-covered tub appears to be infinitely preferable to pot culture. This plant, nevertheless, is well able to conceal, with its long Zulu shield-like leaves, any receptacle it may be grown in. If memory serves me rightly, a plant in its prime at Straffan House, Kildare, had thirty leaves, the later developed one being 5½ feet in length. A fine, bold habited Rambler is the great Passion flower, *P. quadrangularis*, and quite worthy of inclusion in this category.

Giants of the Fern tribe appear to be of too distinguished an order of merit not to have their claims separately considered, hence but a passing thought is given to them here; or is it desirable to enumerate a host of interesting and beautiful foliage plants generally well known and frequently seen? Some gardens there are which seem almost to suffer from an *embarras des richesses* in this direction—viz., overcrowding being detrimental to the best effect. From a botanical point of view, or from a gardening point of view, it is good so far as it goes, but it seldom goes far enough to reach what many aim at, and not a few miss. Nature is the great teacher, and inculcates few finer lessons than where, with some bits of half-draped rock and a few noble foliaged plants, she has “allured to brighter worlds and led the way.”—K., *Dublin*.

PLANTING POTATOES.

THE spell of frosty weather lately experienced has in a great measure pulverised the surface of previously broken up land, and left it in a condition, when sufficiently dried by sun and wind, for readily receiving the tubers of Potatoes. Heavy land is much benefited by frost, as nothing tends to break down the adherent particles so much. After the frost has passed away, and drying winds have extracted the moisture which causes the sticky condition following frost, the land may with advantage be forked over, so as to bring it into a still more friable condition. Soil in a lumpy state is not conducive to a good start, either with roots or seeds, and time spent in thoroughly breaking it down adds greatly to ease in planting, as well as subsequent success with the crop.

The earliest crops of Potatoes with outside culture are best grown on warm sheltered borders, where the soil is light and friable and readily warmed by the sun. Such soil, if deeply cultivated and enriched a few weeks before with a fair amount of decomposed manure and light sandy potting soil, will retain moisture enough to carry the crop to an advanced stage, and with the aid of natural moisture, which may reasonably be expected, a good crop of tubers will be dug in June. For this crop the Ashleaf or kidney varieties are the best.

Their growth may be materially forwarded by sprouting the tubers before planting. This is effected by placing the tubers, rose end upwards, in shallow boxes set close to the glass in a cool house. If this is done, a delay of a week or two in planting will be of little consequence, as care in planting will soon be rewarded in seeing growths above the soil. Plant 4 inches deep, in drills 2 feet apart, and the sets a foot distance. Attention must be given to protect from frost, as the growths are susceptible to injury when May frosts occur. Dry litter spread over them each night when frost is imminent is perhaps the best protection. As soon as high enough soil should be drawn to them.

Successional tubers ought to be planted in a similar position, or failing that, in the open quarters where the ground is in exceptionally good tilth. Although not of deep rooting habit Potatoes seem to succeed better where the soil is deep rather than shallow. Shallow soil cannot long retain moisture, while deeper soil does, and also draws fresh supplies from the subsoil as that at the surface evaporates or is exhausted by the needs of crops.

Drilling is the best method of planting Potatoes. Draw the drills 4 to 6 inches deep, and at the required distance needed by the variety. The early kidney varieties do well in rows 2 feet apart. Stronger growing varieties should be placed 2 feet 6 inches to 3 feet from row to row. Drills which cannot readily be formed with the hoe should be cut with the spade. The use of the dibber for planting Potatoes is not to be recommended. The sets are liable to be suspended in the holes, which vary in depth if not carefully formed.

Medium-sized whole tubers are much to be preferred. If large sets are cut a few good eyes must be retained to each section. Before planting allow the cut parts to dry, dusting them with a little lime.

The whole of March and the first part of April include the best

times for Potato planting. Choose periods when the soil is dry on the surface, so that the ground is not made into a pasty condition by trampling on it when wet. In a dry state no harm whatever accrues from treading the soil, which if light is all the better for being firmed.—E. D. S.

TOMATO CULTURE.

(Continued from page 92.)

WHEN the young plants are grown with abundance of space at all stages, they form a sturdy base, close-jointed stems, well-developed leaves, and push laterals or axillary growths, so-called side shoots. In ordinary practice it is advised to remove the side shoots as they appear, in order “to direct the nourishment to the formation and maturation of the crop, instead of being expended, as it often is, in making superfluous growth.”—(MacIntosh’s “Practical Gardener.”) On this point there can be no question as to its advisability after the first trusses of flowers are formed and the fruits are set; but I am not at all convinced of its propriety until the plant shows for fruit formation.

If the plants are not required for trellises I think it is advisable to allow the side shoots to spring, and, unless very strong, remain until the first trusses for fruit appear. This secures a stout base, any laterals showing undue vigour being shortened to the joint nearest the stem. When the plant shows for fruit side growths may be closely rubbed out, thus directing the nourishment “to the formation and maturation of the crop.”

The Tomato, like the Potato, will grow in almost any medium. It appears to appreciate alluvial soils, and to detest heavy and wet land. The top 2 or 3 inches of pasture land, with its turf, unquestionably grows the healthiest plants, with the heaviest and cleanest produce. For enriching the turf, usually stacked until the herbage has been reduced, nothing answers better than stable or farmyard manure. The amount to be used depends, as well as the form, upon the nature of the soil. For light loam cow manure is preferred, as it is cool and moisture-holding, also closer in texture than other animal manures. Of it not more than one third should be added to the loam. Medium textured loams neither light nor heavy, will be sufficiently enriched by the addition of one-fourth of good farmyard manure, as they generally contain a considerable amount of organic matter. For strong loam horse or stable manure proves most suitable, not adding more than one-third.

The proportions may be varied according to the character of the loam, always having the manure at least half decayed, as it will then have heated, and be more or less freed from vegetable and animal pests. In olden time the manure was used comparatively fresh, placing it between the layers of turf in stacking in about the amounts quoted. Thus the whole mellowed together and formed an excellent blend. The practice hardly commends itself to present day requirements, especially in growing for market. The latter grower cannot always command turf, or even allow it to lie any considerable time, therefore mixes the manure with the soil some little time in advance of planting, and often too fresh. This I consider a mistake, for though more may be got out of it in the form of nitrogen there will be proportionately less available mineral matter, and the plants will grow more in the direction of eelworm and kindred ills than away from them.

The foregoing suggestions may be useful to the uninitiated, for the use of fresh manure mainly profits the plants by the nitrogen, while the other elements come into use too late to be correspondingly beneficial. It is preferable in most instances to rely on top-dressings of rich compost or manure and artificial fertilisers or liquid manure when the fruits commence swelling than to give a very rich soil previously, as this tends to induce too vigorous a growth for productiveness. This, however, depends upon the amount of compost, its firmness, amount of light or space, and management.—G. ABBEY.

(To be continued.)

A HINT ABOUT FUCHSIAS.—When attention is being given to old stock plants of Fuchsias in the way of cutting back and potting, it is well to give heed to the raising of young plants for summer flowering. To meet the demand of present day styles of decoration, small plants of graceful habit are required, and for this purpose Fuchsias raised from cuttings in the early spring are very useful. If young growths from the old stems are broken off and inserted in pots or boxes over a gentle bottom heat, they will root readily, and in due course may be placed in small pots and grown on shelves close to the glass. Before getting thoroughly root-bound remove them into 5-inch pots, and, if necessary, again into a larger size. Keep the main stem growing and supported by a neat stake. Side growths will be emitted from the axils of the leaves, and later on the whole or a portion of the plants can be grown in a cold frame. When in full bloom these small specimens are very effective and useful for various forms of decoration.—G. H.

N.C.S. AND INCURVED VARIETIES.

I FEAR, from "Sadoc's" note on page 142, he thinks I am unduly pushing The Egyptian as an incurved variety, but had he seen the blooms mentioned by me, also the flower of this variety which was awarded the prize for the best incurved at the November meeting of the Bristol and District Gardeners' Mutual Improvement Society, he must have admitted that it is possible to stage it in typical form. I am afraid I cannot offer better credentials for it than these. Of course locality may have something to do with it being seen to what I should say was perfection, it being a well known fact that some districts do not suit some varieties.

As to it being classed as a Japanese variety when introduced, I should attach slight importance to this, and, if I might be so bold, should advise "Sadoc" not to place too much confidence in growers' descriptions of varieties in their first season. Several varieties which were introduced as Japanese are now seen in a good percentage of winning incurved stands. If all the varieties which have any Japanese blood in them were excluded, and we returned to the incurveds of a few seasons back, would the section receive the support of the leading exhibitors who are in the habit of staging in classes for thirty-six incurved? I think not.

It is certainly a laudable object to maintain as high a standard as possible, but not to do it to the detriment of this class of Chrysanthemum; and whilst societies schedule classes for large numbers of incurved, and the public are craving for size, I see no way out of the difficulty but to admit these varieties. Many of our older varieties of incurved are admitted by growers to be deteriorating to such a degree that, if the class is not added to by such varieties, I am afraid we should be sometimes placed in a difficult position to compete in the larger classes.—J. WILKINSON, *Stoke Bishop, Bristol*.

THE VASE CLASS AT THE N.C.S. SHOW.

I WAS rather surprised to read Mr. Molyneux's remarks on this subject in your issue of February 23rd. I think he has overstated the difficulty of the task. Surely it is as difficult to exhibit sixty distinct varieties on a given date! Yet I think sixteen growers were able to do this latter at the Diamond Jubilee Exhibition. Most of the leading exhibitors grow from eight to twelve plants of some two dozen of the leading varieties, and it is a sorry testimony to our boasted knowledge of the Chrysanthemum if five blooms of twelve distinct varieties cannot be chosen from these. It is not necessary that the varieties should be new ones, and I think very few new ones will be good enough to be represented. Most competitors will rely on well known varieties, and will also grow a few extra plants of their favourites. So far from making the conditions easier, I would stipulate that not more than three white or three yellow varieties be shown, and only two of any other colour, and I should like to see the Japanese incurved represented, in say four varieties. It must be remembered that the prize is a special one, and worthy of special effort.—GROWER.

HULL CHRYSANTHEMUM SOCIETY.

THE schedule of the exhibition to be held in the Artillery Barracks, Hull, on November 15th and 16th of this year is just to hand, and continues, as heretofore, comprehensive in style and generous in its prize money. The classes number close upon fifty, and are so arranged as to meet the requirements of all growers, whether large or small. Numerous excellent prizes are offered, and we shall, no doubt, be safe in assuming that this will again prove one of the best exhibitions in the country. It is regrettable to observe that the financial statement shows a deficit of £49 10s. from the balance in hand at the beginning of last year, and we trust that the Committee's appeal for more support will be promptly and generously met by increased and more numerous subscriptions. The Society is one of the best managed in the kingdom, and is deserving of support on all hands. Messrs. E. Harland and Dixon continue as Honorary Secretaries, and most admirably do they carry out their duties.

SHEFFIELD CHRYSANTHEMUM SOCIETY.

ON Wednesday evening, the 8th inst., Dr. Banham delivered a lecture in the Society's Room entitled "A few Chemical Points in Relation to Plant Culture." Commencing with a description of various soils, their advantages and disadvantages, he afterwards referred to the composition of plants and the manner in which plant foods should be

administered. The lecture was a most excellent one, and full of valuable information, much more in fact than is usually carried away from a meeting in the cranium of an ordinary individual. Unfortunately it was not taken down in shorthand, so that its real value to outsiders is lost for lack of the indispensable reporter.

The members' exhibits were Cinerarias for the professionals and bulbs for the amateurs. In the latter section the lecturer (Dr. Banham) carried off first honours.

The meeting closed with a vote of thanks to the lecturer. Mr. T. Gartery occupied the chair.—J. H. S.

THE BEST PEACHES.

I AM pleased to note that two such sterling cultivators as Mr. D. Thomson and Mr. E. Molyneux have contributed exceedingly interesting notes on this subject, which is one worthy of being thrashed out, as we have now many varieties to select from, and all cultivators desire to grow only the best. On page 148 Mr. Thomson fully corroborates my idea that Noblesse is a variety which requires lime in considerable quantities to insure real success, and a useful hint has been elicited as to the conditions under which so noted a fruit grower produced this fine Peach in perfect condition, both in regard to free cropping qualities as well as size of individual fruits. Any Peach tree which I found to be a shy cropper I should at once apply lime to. In the summer by boring holes in the border, filling them with air-slaked lime, scattering some over the whole surface of the border as well, and then watering it in; in the autumn or winter by mixing lime freely with the top-dressing.

Mr. Thomson has hit me very closely by suggesting Dymond as a substitute for Royal George when the latter is subject to mildew. When penning my notes I hesitated some moments as to whether I could not include Dymond in my six, as it is a variety good in almost every way, and if I had named seven Dymond would have made up the number. My reason for not including it was, that although it is one of the surest croppers and colours splendidly, the slight depression at the crown of the fruit is its one weak point.

On page 174 Mr. Molyneux mentions the case of a market grower who has discarded Royal George on account of its susceptibility to mildew. I have great faith in the market men, as the question of £ s. d. quickly causes them to root out any plant, tree, or flower which shows a weak point. If I found mildew troublesome I should follow the same course with Royal George or any other variety, but so far I have only once experienced any difficulty in the matter. That was about fifteen years ago, when foreman at Preston Hall, in Kent. In the early house there was a splendid tree of Royal George, and on one side of it mildew often put in an appearance, but this was invariably checked at once, and seldom gave further trouble.

I cannot see my way to cut out Alexander from the best three early varieties for the reason which Mr. Molyneux gives, as although the flavour is not quite first-rate it is the earliest variety grown; that means much in private and market gardens. In regard to Walburton's Late Admirable, I have never found the flavour passable when grown in a late house. Mr. Inglefield of Tedworth, in Wilts, used to exhibit it in grand condition in August, and if I grew it at all it would be in a midseason house, for the sake of the splendid fruit it produces.—H. D.

WE have now for several years past given up the cultivation of Peaches on the open walls. They were at one period grown largely, but, owing to a succession of inclement seasons, little benefit was obtained from them. The one variety, however, that could always be depended on to carry a heavy crop of large fruit was Walburton Admirable, and if the autumn were fine it was of fair flavour. Could we depend on similar weather to that experienced last year the outdoor cultivation of Peaches in the North would be a success; but, as it has been in the past, so may we expect it to be in the future.

We now cultivate Peaches extensively under glass, and have thus exceptional opportunities of testing the different varieties. I may at once state the fact that the majority of them are grown with a view to making as high a price as possible. But this is not the sole aim, as quality and appearance must be studied for home consumption.

Bearing these facts in mind I do not consider "H. D." has made the best selection of varieties for that purpose. Alexander is recommended as a good commercial investment by obtaining ripe fruit in May. This is not our experience, as it is only of medium size, very thin in the skin, and a bad packer. If planted in a mixed house there is a difficulty in obtaining a full crop of fruit owing to the habit it has of dropping its buds. We find that a good midseason variety that ripens its fruit from the beginning to the end of June will make double the price in the open market to those bearing smaller fruit a month earlier in the season; consequently we are gradually working out this variety, and also Royal George, the varieties of Grosse Mignonne and Alexander Noblesse.

The two former varieties will be displaced by Crimson Galande, Bellegarde (probably the two best midseason Peaches in cultivation), Stirling Castle, Violette Hâtive, and Belle de Doué (a variety of Bellegarde). These are all small flowering and very free setters. They are of hardy constitution, carrying a heavy crop of large, well-coloured fruits, which are second to none for flavour, and may always be depended

on to make top prices in the market, as well as being appreciated on the dessert table.

Mr. Thomson refers to a dish of Noblesse exhibited by him in 1865, but this variety would now stand little chance against the varieties mentioned above. With reference to this variety an amusing incident happened not many years ago in a neighbouring county, where a large house party had assembled. Amongst them was a noted clerical gentleman who was much interested in gardening. The gardener was desirous of placing some of his best products on the table. The only Peaches ripe at that time were Noblesse, large fruit, but wanting in colour. He consulted the cook, who supplied him with some artificial colouring. The fruit was duly operated on with a fair amount of success, and was placed on the table. No remark was passed, and all was supposed to have gone well. But judge of the gardener's feelings the next morning on meeting the clergyman, who remarked, with a twinkle in his eye, "Those Peaches were very good, but don't you think you laid the colouring on rather too thick?"

I can corroborate all "H. D." says in favour of Sea Eagle, and if only one sort for late use is required this is the variety to plant. Barrington may always be relied on to carry a heavy crop of large well coloured fruit. In some soils this variety drops its fruit more than is desirable whilst stoning. It does not do so, however, on our limestone formation. I prefer the latter to Golden Eagle, which requires a long season of growth to grow it to perfection. Walburton Admirable is a shy cropper under glass.—S., *Yorks.*

HAVING read with interest the notes on this subject, I trust the following will be received in a cordial spirit. I cannot but be surprised that Barrington has had such scanty notice accorded to it. It is a Peach of noble appearance, fruits freely, and is of good quality when ripe; not quite so exquisitely flavoured as some possibly, but it should be included amongst the late sorts if only because it is such a free setter and generous bearer. Bellegarde can hardly be left out, or Dymond and Stirling Castle. Royal George with me is subject to mildew, otherwise it would be recommended. Alexandra Noblesse is grand, worthy a place anywhere. Sea Eagle, again, as a late variety, is fine. As an early I find Alexander cannot be dispensed with. I have not grown Waterloo. Hale's Early is one of our best as second early, and is a handsome productive Peach. Why is Crimson Galande not mentioned? It is a first-season variety, colours splendidly, bears abundantly; in short, as a mid-season variety has been one of my best. These remarks pertain to outside culture only.—KITCHEN GARDENER.

PRIMROSES AND POLYANTHUSES.

MANY persons have a genius for taking trouble. They do many things that are unnecessary, and may indeed be better done if the simplest course be adopted, but then there is no genius involved in such procedure. I felt that must be the characteristic of a writer who advocated the sowing of seeds of Primroses and Polyanthus in pots under glass, and later pricking the seedlings out into a cold frame, later replanting finally outdoors. Now were these plants tender I could understand the need for all this care and concern, but seeing that they are hardiest of the hardy, it does seem as if the advice tendered was very needlessly inexact.

I have grown as many of these plants as most persons, having for many years raised several thousands annually from seed, and I both sowed outdoors in the autumn and in the spring, in both cases getting ample growth and numbers of hard sturdy plants. But I prefer sowing about the last week in August for one or two reasons. In the first place, when the seed is sown soon after it is ripened the coats, usually hard, are less so than they are after having been stored for the winter. Then not only is growth more even, but strong plants are obtained to stand the winter in the seed beds, where they winter well. Finally, there is the advantage of being able to put out the plants where wanted to bloom direct from the seed beds, in April or May, just as it may be convenient, and the plants then become deeply and firmly rooted ere hot dry weather sets in, such as we commonly experience in the summer. That is great gain, as plants raised in the spring, even under glass, have to be planted out in June or July, when the weather is often hot and dry.

In addition, there is the gain of getting in flower the following spring plants so large relatively that they make a wonderfully fine show. I have commonly had plants to flower thus fully 12 inches across, and having huge heads of bloom. How simple and satisfactory is this method! But plants raised by sowing seed outdoors in April on fine soil, keeping it watered and shaded until good growth results, are always satisfactory for those who cannot get seed to sow earlier. Polyanthus and Primroses are deep rooted, and once well hold of the ground soon hold their own without much watering being needed. Still, when planted out afresh in the summer water must be given a few times at the first to enable them to secure a hold.

Wherever these hardy spring flowers are grown it is wise to make a sowing every year. In some soils and situations plants, after blooming time, begin to die off or are eaten up with spider in the summer, or the crowns become so thick that they are incapable of sustaining good leafage; hence it is so much better to have a succession of young plants to replace them. It is better, too, than lifting and dividing the old ones, except where the soil is deep and the atmosphere moist. Whenever that form of increase is adopted it is well to do it in the spring, hard cutting back the root stems, and thus compelling the formation of new roots.—A. D.

NOTES FROM THE GARDEN ISLE.

MR. FRANK ORCHARD, who for the past seven years has had charge of the gardens of H. Mitchell, Esq., Undermount, Bonchurch, I.W., has left the above, and joined his brother, Mr. C. Orchard, in his business at The Harbour Gardens, Bembridge, Isle of Wight.

J. Thornycroft, Esq., the head of the famed torpedo boat-building firm of Chiswick, and of Steyne House, Bembridge, has purchased nearly the whole of the reclaimed land at Bembridge Harbour, and part of the Bembridge Lodge Estate, from the United Realisation Company, and is developing and improving the property.

The Technical Committee of the Shanklin, I.W., District Council arranged with Mr. C. Orchard of Bembridge to give a lecture on "Hardy Fruits Applicable to the Isle of Wight," at the Institute, Shanklin. The lecture was illustrated by large coloured diagrams. Varieties of Apples, Pears, Plums, Gooseberries and Raspberries, which experience had proved to do well in the Island, were mentioned, and the special feature which made each variety valuable. The growing of Figs was strongly advocated, the climate of the Island being specially favourable to the growing and ripening of this fruit. Grading and sorting Apples as to size and colour was strongly recommended. The establishment of a central wholesale market for fruit was advocated as essential in helping the growth of an industry for which the locality was in many respects especially favoured.

Vegetation in the Isle of Wight is not quite so forward as last year, which was an exceptionally early one to a certain date. Frosts have occurred frequently; on Tuesday morning, February 28th, 10° was registered. The sun during the day has shone brilliantly, tempting the honey bee to leave the hive and visit the yellow Gorse bushes. Crocuses and other spring flowers are now in good bloom, as is *Prunus Pissardi*. The heads of the early Asparagus crop are showing through the surface of the soil, only to be cut off by the frosts. The hardy bush fruit trees are bristling with flower buds, which the weather is keeping back, and everything so far points to a very favourable season.—ISLANDER.

BALSAMS.

IN order to have fine plants of Balsams, say 3 feet high and as much in diameter at the base, seeds should be sown about the end of March in light rich soil in pots or pans, and placed in a warm moist place, such as a two-light frame on a gentle hotbed. If the place can be entirely devoted to the Balsams so much the better, and a piece of glass placed over the seed pan will assist germination. As soon as the seedlings can be handled they should be placed in small pots, using slightly richer soil than that in which the seed was sown. Keep them plunged in the frame with their foliage not more than 6 inches from the glass, for the object is to promote a quick and sturdy growth, and the warmth in the bed will incite a healthy and rapid root action. Shade them from strong sunlight, and afford a little ventilation so long as the temperature can be kept above 70°.

Do not allow the plants to become root-bound, but transfer them into 5 or 6-inch pots as soon as the roots are working freely round the sides. This remark applies with equal force to the future, as any check at the roots will cause a premature formation of flower buds, and thus render it almost impossible to obtain a large, well-flowered, and symmetrical specimen. At this potting the soil should be rich, but neither too light nor too heavy. If the loam at hand is light, then all that need be added will be a fourth of its bulk of dried cow manure passed through a sieve, but should it be stiff and heavy in texture then a third of the bulk must be leaf soil, or, failing that, sand.

Let the drainage be perfect, but not necessarily bulky. The soil on all occasions ought to be warm when used, and the plants sunk deeper at every potting operation. Keep them plunged in the hotbed, and not too close together; apply water carefully, and allow a free circulation of air according to the temperature.

Subsequently pots 9 inches in diameter may be used, and soil as before described. If there is no longer sufficient head-room in the frame, let the plants be placed close to the glass in a warm greenhouse, taking care to maintain an atmosphere as near like that of the hotbed as possible. As the side shoots develop tie them down close to the pot. It is a good plan to pass a wire or string round the pot underneath the rim, to which strands of matting can be attached from the shoots above. Occasional weak supplies of liquid manure may be given as soon as the roots have taken to the new soil.

If flower buds show, keep them picked off for the present until the plants are established in their largest pots, which need not be larger than 12 inches in diameter. The soil for the final potting ought to be sound fibrous loam—if it has been stacked nine months and had a layer of manure between each two layers of sods it will be just right—three parts; cow manure one part, and a dash of sand. Let the plants be potted rather firmly. Stake and tie out as the potting is completed, and return to their growing quarters. Take care to shade at all times from strong sunshine, and as the plants come into flower give them a cooler atmosphere and feed with liquid manure as they require it. Keep all seed pods picked off. Those who possess them may place a few crushed bones over the crocks at the final potting.—F.

THE UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.

OUR only horticultural benefit society continues to grow in size and importance, as healthy institutions have a knack of doing, and its annual business meetings are usually well attended. The 1899 fixture, which took place at the Caledonian Hotel, Adelphi, Strand, on Monday evening last, was rather an exception in this respect, for the attendance was certainly meagre. This might have been brought about, as was suggested, by the knowledge possessed by the members that all affairs were right and satisfactory. Be that as it may, everything worked without a hitch, and there was no demur raised to anything. Mr. J. Fraser, of "The Gardening World," took the chair at eight o'clock precisely.

After the customary preliminaries had been disposed of the report and statement of accounts were presented by the Secretary, Mr. W. Collins, and the Hon. Treasurer, Mr. Jas. Hudson. The adoption of the report and statement of accounts was formally moved by the Chairman, seconded by Mr. Coates, and carried *nem. con.* It is pleasing to know that the several funds are in excellent condition.

This done, the Chairman reviewed at some length the scope and object of the Society, as well as its working and present status. Mr. Fraser expressed surprise that a society like the "United," which could fairly claim to be national, could be carried on with so little expense of management, and suggested that the secretarial duties were performed by Mr. Collins more as a labour of love than for the sake of emolument. After touching upon the benefits to be obtained by members in the way of sick pay—18s. per week for twenty-six weeks, and 9s. per week for another twenty-six weeks in each year, for the upper division, and 12s. and 6s. per week for the same respective periods in the lower division—Mr. Fraser laid special stress upon the provident section of the Society. Under this section a certain amount was laid aside each year to the credit of each member, these deposits bearing interest until both principal and interest were withdrawn by the member on attaining the age of seventy years, or previously by his heirs or executors in the event of death. The Benevolent Fund was warmly praised, and Mr. Fraser concluded by advising every member to do his best individually to bring other members into the fold.

It was resolved, following the proposal of Mr. A. Hemsley, to print 25,000 copies of the report in addition to those required for the members, in order that by being distributed they might advertise the claims of the Society. The meeting was scarcely moved out of the even tenor of its way even by the election of the committee-men, although there certainly was a thrill of animation. The retiring members, Messrs. H. Peerless, E. Burge, and W. Foreman, were re-elected; and Messrs. Summers, Taylor, and C. F. Harding were chosen to fill the places of Messrs. N. Cole, G. W. Cummins, and E. G. Wheeler. Mr. Harding goes on Committee as a representative of the journeymen gardeners.

Mr. W. Collins' value as Secretary is so well known that his re-election was simply a matter of form. Thus Mr. A. Hemsley found the meeting entirely with him in his appreciation of their worthy Secretary, as did also Mr. J. Hudson, who supported the motion. Mr. Hudson mentioned incidentally that the turnover between himself and Mr. Collins during the past year had been £2000, and although each kept books independently of the other, they were found upon comparison at the end of the year to tally even to a penny.

Hitherto a member of the "United" has not had an official emblem of membership; but this defect has now been made good, and a very handsome emblem designed by Mrs. Harvey (*née* Miss Lilian Hudson) has been accepted, and samples of it, both framed and unframed, were on view. The design itself is 13 inches by 10 inches, and the price will be 1s. 6d. The accompanying illustration, which has been prepared from a photograph, is a reduction of the original, and brings out admirably its salient features. Now the Society has an emblem as well as a motto, and both are worthy of it.

Votes of thanks to the Committee, the Hon. Treasurer (Mr. Jas. Hudson, who has been connected in an official capacity with the Society for some fourteen or fifteen years), the Trustees, the Horticultural Press, and the Chairman, were all passed through hands with great good humour and celerity. Judging from appearances everybody connected with the Society seems to like work, and consequently to work well.

NOTES ON ALPINE FLOWERS.

WULFENIA CARINTHICA.

WHILE it is more pleasing to write of plants which will give satisfaction to growers, it is none the less needful to tell of those which hardly repay the trouble—even if it be small—of growing them. *Wulfenia carinthica* is one of the latter class, and is so because of its very shy flowering. The writer has known it in gardens for years without producing a single bloom, and in others where a large plant gives an occasional spike. He does not, however, know any place where it blooms with the freedom it ought to show to cause it to be recognised as a good alpine flower. It is also liable to perish in winter if allowed to form large plants. This *Wulfenia* was introduced from the Carinthian Alps about eighty years ago, and the genus was named in honour of Francis Xavier Wulfen, a botanist who was the author of a work on the plants of Carinthia. It belongs to the natural order of *Scrophularineæ*, and has a loosely arranged spike barely a foot high, bearing blue flowers, which are somewhat drooping. *Wulfenia carinthica* is propagated by seeds or division, and may be grown in a rather peaty soil. The plants ought to be divided in April if increase is desired.

ERYTHRÆA MASSONI.

This is, it appears, the correct designation of a little plant best known by the name of *E. diffusa*. One cannot but qualify this statement by saying that the plant is little known, because of the difficulty some find in retaining it as a permanent occupant of their gardens. It frequently dies with many after flowering. With the writer it has been more complaisant, and he has had, and still has, one plant in the same position that it has occupied for seven or eight years. In his garden it is grown in light sandy peat soil on the raised edge of a path, and where it is partially shaded in summer by tall herbaceous plants. One requirement is carefully attended to in summer; this is a plentiful supply of water in continued dry weather. In light very well-drained soil this little plant has a thorough soaking of water when it appears to be becoming in need of same.

E. Massoni is a charming little flower of a reddish purple, not unlike a dwarfier and prettier form of the native dwarf Centaury, *E. Centaureum*. It is increased by division or by seeds. The latter is the more convenient method, and gives better results. Seeds are freely produced, and may be sown as soon as ripe, or in spring. *E. Massoni* is a native of the Azores, but has proved quite hardy with the writer, never receiving any protection in winter. While partial shade, as is previously mentioned, is given here, the plant ought not to be overhung by other flowers. It opens in sunny weather.

ERYTHRONIUM AMERICANUM.

On page 94 *E. Hartwegi* was briefly spoken of, and the writer now desires to refer at greater length to a plant which has been introduced for a long

time, but which has given a great deal of trouble to cultivators. This is *Erythronium americanum* (the American Dog's-tooth Violet)—an unfortunate name, seeing that we have now so many *Erythroniums* from across the Atlantic. The troublesome feature of this Dog's-tooth Violet is its refusal to flower under the treatment which proves so satisfactory with others. This appears to be caused by its splitting up into small offsets, which go so deeply into the soil as to become unable to flower. The way to prevent this is to enclose the plants within stones all round and at the bottom. A good stiff soil is also an advantage. The flowers of *E. americanum* are yellow, and it is a pretty and pleasing plant where it does well.

CAMPANULA SOLDANELLEFLORA.

The Soldanella-flowered Campanula is little seen, and it is not often that one finds it offered for sale. It partakes in its general features of the style of the native Campanula rotundifolia, or of *C. Hosti*. The flowers of what one may call the preferable form are semi-double, and are remarkably pretty and uncommon looking in a collection of the smaller Bellflowers. It grows 9 inches or a foot high. Increase of *C. soldanellæflora* is effected by means of division or cuttings. It may be also raised from seeds, but only a proportion of the seedlings will come semi-double. Some raised by the writer presented a good deal of variation. There were the semi-double form in perfect condition; flowers similar to those of the Harebell or *C. Hosti*, and others with narrow, deeply cut segments varying in size. *C. soldanellæflora* grows well in almost any moderately heavy soil, and lasts longer in bloom if in slight shade, but not overhung by other plants or by trees.—ALPINUS.

ROYAL GARDENERS' ORPHAN FUND.

"A. D." makes some pertinent remarks on the above Fund in your issue on February 23rd, page 153. He deplores the fact that not one of the fathers of the nineteen children nominated for election this year had been a subscriber to the charity, and refers to the indifference of gardeners generally in not becoming subscribers, and asks, Can anyone explain it?

I am afraid it is difficult of explanation. A glance at the list of subscribers for 1897 reveals the fact that many men occupying prominent positions as head gardeners do not subscribe to the Fund, and who, we may assume, could well afford the sum of 5s. or more per annum. It is possible the claims of the Fund have not been brought home to them by personal solicitation.

But the large majority of gardeners are poorly paid, and can ill afford even the small annual sum of 5s., and especially as they have no guarantee that their children will receive the benefits of the Fund should they require it. As a worker for eight years on behalf of the Fund, I have solicited scores of gardeners to become annual subscribers, and what is the result? I have four gardeners on my book, the remainder being nurserymen and private ladies and gentlemen. Some whom I have asked say, "We have no guarantee that we shall receive any benefit; we have no voice in the management, as we live at too great a distance from the place of meeting, and it is those living near who can do as they like and pull the strings on behalf of any candidates for election."

I do not endorse these views, as I have every confidence in the Executive Committee, and I should like to impress on the great body of gardeners the necessity of becoming annual subscribers; and if there is anything in connection with the Fund they do not approve of, let them make it known through the horticultural press or otherwise.

The time will come when it will be the children of subscribers who will benefit by the Fund. But it must not be two children from one family to the exclusion of children from other families, whose claims are equal or perhaps more deserving. At the last annual meeting the following was added to Rule XI.—"Not more than two children of the same family can be in receipt of the benefits of the Fund at the same time." Previously the rule did not specify how many children from one family might receive the benefit of the Fund. But why should two of one family receive the benefit of the Fund while other families are left out? Surely the Fund is meant to benefit a number of families and not the few. At the present time eight families have each two children on the Fund, each child being allowed 5s. per week.

Mr. A. Dean suggested that at a future time it would be expedient to insist that there must be four children under twelve years of age in a family before two of its members could be on the Fund at the same time. I do not agree with him there. I suggest that only one child from a family shall receive the benefit of the Fund, unless under exceptional circumstances, such as the loss of both parents. I would further suggest that should the circumstances of the case require it, the child of a deceased subscriber who has subscribed for five or more years shall be entitled to the benefit of the Fund without election; or the child might be allowed twenty or more votes for each year the father had subscribed.

I know these suggestions require consideration, but it is in the interest of the Fund I make them, and I expect to hear the opinions of others; and possibly the Executive Committee may be induced to consider them, and so make the Fund of still greater benefit, and perhaps by so doing the great body of gardeners will be encouraged to become subscribers.—J. B. STEVENSON, *Hon. Local Secretary, Bournemouth.*

ROYAL HORTICULTURAL SOCIETY.

DRILL HALL.—MARCH 14TH.

ON Tuesday last the Drill Hall presented a very gay spectacle despite the heavy fog which enshrouded this and other parts of London. Every table was requisitioned to almost its fullest extent with splendidly diversified exhibits of excellent quality. Orchids were magnificent, and considering the weather, large in numbers, but of course miscellaneous floral displays formed the backbone of the exhibition. Apples were admirably shown from Withington, Hereford, and Sittingbourne.

FRUIT COMMITTEE.—Present: Geo. Bunyard, Esq. (in the chair); with Messrs. R. Fife, J. Smith, G. Wythes, W. Pope, W. Bates, W. Iggulden, A. Dean, S. Mortimer, A. F. Barron, J. Basham, E. Shaw-Blaker, and J. H. Veitch.

The collection of Apples from Mr. J. Watkins, Withington, Hereford, was an excellent one, and comprised many varieties that are not customarily seen in good condition at this period of the year. Almost the whole of the fruits were firm, of large size, and exceptionally rich in colour. Amongst the most conspicuous were Lord Derby, Hornead's Pearmain, Beauty of Kent, Lane's Prince Albert, Hanwell Souring, New Bess Pool, Dumelow's Seedling, Annie Elizabeth, Catshead, Claygate Pearmain, Sandringham, The Queen, Bramley's Seedling, Histon Favourite, Flower of Kent, Buxton's Pearmain, Wadhurst Pippin, Blenheim Pippin, Cox's Pomona, Flanders Pippin, Wealthy, Reinette du Canada, Nelson's Codlin, Brabant Bellefleur, Newton Wonder, and Brownlee's Russet.

Mr. A. J. Thomas, Rodmersham, Sittingbourne, the well-known producer of Pear, was represented by a collection of Apples, which were tabled in most creditable condition. The individual fruits were not large, but they were sound and of high colour. Particularly noteworthy were Betty Geeson, Blue Pearmain, Hanwell Souring, Lady Henniker, Glory of England, Old Russet, Barnack Beauty, Striped Beefing, Chelms-

ford Wonder, Newton Wonder, The Queen, Sandringham, Gloria Mundi, Bramley's Seedling, Annie Elizabeth, Lane's Prince Albert, Bismarck, and Lord Derby.

Mr. John Russell, Richmond, exhibited Seakale Russell's Solid Ivory; a very good form. Mr. G. Baker, gardener to H. A. Blythe, Esq., Stanstead, staged a dish of *Cyphomandra betacea*. Mr. J. Masterson, gardener to the Earl of Camperdown, Shipston-on-Stour, exhibited good dishes of Blenheim Pippin, Allen's Everlasting, and Royal Russet, also excellent dishes of Uvedale's St. Germain.

Mr. T. J. Gilbert, Bourne, Lincoln, sent dishes of Bergamotte d'Esperen, Cox's Orange Pippin, Bramley's Seedling, and Barnack Beauty. Mr. J. Cocks, Peterborough, sent a good bundle of well grown Leeks. Mr. J. Crook, Forde Abbey, Chard, exhibited four dishes of Apples, comprising good specimens of Cowarne Quoining and Marget's Seedling. Mr. G. Kent, gardener to L. Solomons Esq., Dorking, exhibited a dish of new Potatoes of good size and very well formed.

FLORAL COMMITTEE.—Present: C. E. Shea, Esq. (in the chair); Messrs. C. T. Drury, H. B. May, R. Dean, R. Wilson Ker, Wm. Howe, Thos. Peed, C. E. Pearson, J. W. Barr, J. D. Pawle, G. Gordon, E. H. Jenkins, C. R. Fielder, E. T. Cook, C. Blick, D. B. Crane, J. Walker, H. J. Jones, E. Mawley, J. Fraser, C. Jefferies, and W. Marshall.

Messrs. Wm. Paul & Son, Waltham Cross, sent a very fine collection of Camellias in pots. The plants were literally covered with flowers, and appeared to be in the pink of condition. The white varieties were represented by Alba Plena, Fimbriata, Montironi, Princess Charlotte, Mathotiana alba, a splendid white form of the old favourite, and Donna Maud Pia; while such varieties as the Marchioness of Exeter, Exquisite, C. H. Hovey, L'Avenir, Pride of Waltham, and Madonna constituted a strong force in the coloured varieties. Ten boxes of cut blooms in still greater variety formed a good front to this excellent and interesting display.

The St. George's Nursery Company, Hanwell, again contributed a fine display of Cyclamen, about 130 plants being staged in their well known style. The blooms were very fine, and consisted of a great variety of colours, while the plants themselves could only be classed as excellent. Messrs. J. Hill & Son, Edmonton, occupied one side stage, running the length of the hall, with a capital exhibit of Ferns, and a few other foliage plants; *Adiantum tinctum*, *Blechnum brasiliense*, *Pteris tricolor*, *Nephrodium erythosorum*, *Pteris arguta*, *Blechnum occidentale*, and *Doodia aspera multifida* were conspicuous with their tinted foliage, and made a very attractive exhibit. Mr. John R. Box, Croydon, staged a capital strain of Cinerarias, the plants being exceedingly dwarf, and the colours bright and varied, a first-rate strain.

Messrs. R. & G. Cuthbert, Southgate, made an attractive exhibit of Azalea mollis and Ferns. The majority were seedlings, with a few named varieties. The plants were just masses of flower, in many varied tints, and the Ferns formed quite a relief to so much colouring. Messrs. R. Wallace & Co., Colchester, staged a very interesting display of Irises, such as *I. persica*, with its remarkable colouring, *I. assyrica*, and *I. stylosa*, also a few *Mu. cari*.

Captain Holford, Tetbury, undoubtedly contributed the chief feature of the meeting with a magnificent display of Hippeastrums, that occupied one side of the centre staging, running the entire length. The plants were growing in 6-inch pots, many of them carrying two spikes of bloom. The colours were exceedingly bright and varied, and no doubt great strides are being made to improve the shape of the blooms. A truly fine exhibit. Mr. H. B. May, Edmonton, arranged a group of Clematises in full flower, but the effect was quite destroyed by the light from the windows behind them. The varieties Lady Londesborough, Miss Bateman, Fair Rosamond, Lord Londesborough, and Sir Garnet Wolseley were most notable.

Messrs. Barr & Son, Covent Garden, staged an extensive display of spring flowers. The chief were the numerous forms of Narcissi, which were well shown. The Queen of Spain, Madame de Graaff, Empress, Emperor, W. P. Milner, Albicans, and Cyclamineus major were very attractive, as were also a collection of Polyanthus Narcissi. *Helleborus viridis graveolens*, and *H. Colchicus* Lothair, with Anemones, Crocuses, and Lachenalias contributed to the display. Messrs. F. Sander & Co., St. Albans, exhibited plants of *Deutzia Lemoinei*, a cross between *D. gracilis* and *D. parviflora*. Messrs. Thos. Cripps & Son, Tunbridge Wells, sent a group of Clematis in pots, also boxes of cut bloom.

Mr. G. Mount, Canterbury, opened the ball in the Rose world with a beautiful display. The Teas were excellent, and the colour in the Hybrid Perpetuals beyond reproach. The boxes contained capital blooms of Captain Hayward, Mrs. J. Laing, and La France, Niphetos, Catherine Mermet (grand), and Bridesmaid, while the blooms displayed in vases carried excellent foliage. Messrs. J. Veitch and Sons, Chelsea, contributed baskets of *Deutzia Lemoinei*, *Azalea mollis*, *Spiraea confusa* (media), and *Azalea linearifolia* backed by Palms.

ORCHID COMMITTEE.—Present: H. J. Veitch, Esq. (in the chair); and Messrs. J. O'Brien, de Barri Crawshaw, T. W. Bond, J. Colman, H. Little, F. Sander, A. Outram, H. J. Chapman, W. H. Young, H. Ballantine, E. Hill, H. T. Pitt, J. Jaques, W. H. Protheroe, C. Winn, J. G. Fowler, and S. Courtauld.

The usual corner of the Orchid table was occupied with a beautiful collection from Messrs. J. Veitch & Sons, Ltd., Royal Exotic Nurseries, Chelsea. The plants were fairly numerous, but the principal attraction was found in the excellent quality of the richly coloured flowers. There was, too, no stiffness observable in the arrangement, and this alone made the stand very interesting. Such *Dendrobiums* as *Euosmum leucopetrum*, *Cybele*, *nobile*, *Pitcherianum*, *Euryales*, *Wardiano-japonicum*, *Edithæ*,

Ainsworthi intertextum, Euosmum delicatum, subclausum, and Wiganæ were charming. There were also Epidendrum elegantulum, Cymbidium eburneo-Lowianum, Epiphronitis Veitchi, Cypridium Godseffianum, C. Alice, Cirrhopetalum picturatum, Cattleya Trianae nivalis, and others, with Phalaenopsis Aphrodite in superb form that was raised from seeds saved at Messrs. Veitch's Langley nurseries.

Orchids were sent from Mr. W. H. White, Orchid grower to Sir Trevor Lawrence, Bart, Burford Lodge, Dorking. The most conspicuous of the many fine plants included Dendrobium Juno, burfordiense, Wiganæ var. xanthochilum, nobile Amesiae and nobile Burford var., with Chysis Chelsoni, Masdevallia ignea Boddarti, Cypridium hirsuto Sallieri, Phaius Cooksoni, Cymbidium eburneum, Masdevallia Harryana, Cattleya Trianae Reine des Belges, Cœlogyne pulchella, C. conferta, Bulbophyllum barbigerum, Lælia harpophylla, Galeandra Devoniana, Brasso-Cattleya Lindleyana, Vanda Mooreana, Spathoglottis Lobbi, Epidendrum Endresii, Bifrenaria Harrisonæ aurea, Epiphronitis Veitchi, Catasctum barbatum spinosissimum, and Odontoglossum crispum, polyanthum xanthotes, luteo-purpureum sceptrum, and Andersonianum. Mr. White also sent a group of Calanthe Sanderiana.

Cœlogyne and Dendrobium made the bulk of the stand arranged by Messrs. B. S. Williams & Son, Upper Holloway, in which Ferns and Palms were interspersed amongst the Orchids. The Cœlogyne cristata alba were very beautiful, as were the numerous Dendrobiums. There were also Lycaste Skinneri, Ada aurantiaca, Oncidium sarcodes, Cymbidium Lowianum, Odontoglossum crispum, several Cypridium, and others. Messrs. F. Sander & Co., St. Albans, sent Cypridium Furzianum, Dendrobium Wardianum, Cattleya Trianae var., Phaius Traceyanum, and Odontoglossum mulus. Acalypha hispida (Sanderi) and other plants also came from St. Albans.

Messrs. H. Low & Co., Bush Hill Park, made up a very showy exhibit of Orchids, in which Cattleya Trianae in variety showed to advantage. Cypridium were also very fine, as were Odontoglossum and others. Messrs. Charlesworth & Co., Heaton, Bradford, contributed a most diversified group of Orchids that attracted a considerable amount of attention. Phaius Norman in variety, Cattleya Trianae, Cypridium, Dendrobium, Odontoglossum, and Cymbidium were all represented. The splendidly grown plants were all carrying substantial, well-coloured flowers.

Mr. H. Ballantine, gardener to Baron Schröder, The Dell, Egham, exhibited several spikes of Odontoglossum that well illustrated the excellent culture to which The Dell plants are subjected. De Barri Crawshaw, Esq., Sevenoaks, showed Odontoglossum Rossi Crawshayanum, O. R. rosefieldensis, O. Ruckertianum, and one or two others. Cypridium were staged by Mr. A. Waits, gardener to J. F. Ebner, Esq., Beckenham; and Mons. C. Maron, Brunoy, France, exhibited a few superb Orchids, including Lælio-Cattleya Impératrice de Russie. Messrs. Jules Hye, W. E. Ellis, W. C. Walker, and others each sent a few plants of more than average merit.

MEDALS.—Fruit Committee: Silver-gilt Knightian medal to Mr. J. Watkins, and a silver Knightian medal to Mr. A. J. Thomas. Floral Committee: Gold medal to Capt. Holford; silver-gilt Flora medal to Messrs. W. Paul & Son; silver Flora medals to Messrs. H. B. May, R. & G. Cuthbert, and the St. George's Nursery Co.; bronze Flora medals to Messrs. J. R. Box and T. Cripps & Son; silver-gilt Banksian medal to Mr. G. Mount, and a silver Banksian medal to Messrs. J. Hill & Son. Orchid Committee: Silver-gilt Flora medals to Messrs. W. H. White and Charlesworth & Co.; silver Flora medals to Messrs. J. Veitch & Sons and H. Ballantine, and silver Banksian medals to Messrs. B. S. Williams & Son and H. Low & Co.

CERTIFICATES AND AWARDS OF MERIT.

Apple Barnack Beauty (J. Gilbert).—This is an Apple that is widely cultivated, and is familiar to every fruit grower. The award was given to it as a market variety (award of merit).

Apple Allen's Everlasting (J. Masterton).—An old Apple, that is not remarkable for its beauty. It is over medium size, has very prominent angles, extending the whole depth of the fruit; the large eye is very deeply set; the colour is dull green, plentifully marked with russet (first-class certificate).

Azalea mollis Purity (R. & C. Cuthbert).—A creamy white variety of the usual type (award of merit).

Hippeastrum Robin (Captain Holford).—A good crimson, with a well marked throat (award of merit).

Hippeastrum Virginia (Captain Holford).—A rose flaked form with a good white ground (award of merit).

Hippeastrum Apple Blossom (Captain Holford).—A grand form, rose coloured, beautifully pencilled and veined (award of merit).

Hippeastrum Murilli (Captain Holford).—A deep glowing crimson, of grand form and texture (award of merit).

Cypridium Talisman (Jules Hye).—This is a very distinct form. The colour is very dark blackish crimson, and the whole flower has the appearance of being varnished (award of merit).

Dendrobium Wiganæ xanthochilum (W. H. White).—A lovely yellow form. The flower is most chaste and beautifully formed (award of merit).

Lælio-Cattleya Impératrice de Russie (C. Maron).—This has resulted from a cross between Cattleya Mendeli and Lælia Digbyana. It is superb. The sepals and petals are delicate rose, and the heavily fimbriated lip is soft blush (first-class certificate).

Masdevallia ignea Boddarti (W. H. White).—A superb variety of glowing scarlet colour (award of merit).

Odontoglossum crispum The Sultan (Jules Hye).—A magnificent variety. The central colour is bright chocolate edged and occasionally spotted with white (first-class certificate).

Odontoglossum excellens Hyeanaum (Jules Hye).—A very finely proportioned flower. The yellow ground colour has blotches and spots of brick red (award of merit).

Odontoglossum Duke of York (W. Stevens).—One of the loveliest flowers in the Hall. The broad petals are white with red spots of varying sizes; the narrower sepals are of similar colour. The lip has a circular patch of red within the fimbriated margin (first-class certificate).

Odontoglossum Mrs. J. Lehmann (J. Lehmann).—A starry flower with large reddish brown blotches on the white ground (award of merit).

Phalaenopsis Cassandra (J. Veitch & Sons).—A chastely beautiful hybrid that resulted from a cross between P. Stuartiana and P. rosea. The sepals and petals are pure white with numerous rose-coloured spots at the base. The lip is patched with rose, and has white on the front lobe (award of merit).

Phalaenopsis Hermione (J. Veitch & Sons).—The parentage of this hybrid is uncertain, but it is possibly from a cross between Stuartiana and Luddemanniana. The ground colour is almost wholly obscured by the rose-coloured spots. The lip is wholly rose-crimson (award of merit).

Sophrolalia iata superba (J. Veitch & Sons).—This bigeneric hybrid resulted from a cross between Sophronitis grandiflora and Lælia Dayana. The flower is almost identical with the first named parent (award of merit).

THE YOUNG GARDENERS' DOMAIN.

DOUBLE VIOLETS.

THERE are few gardens where Violets are not grown more or less, for the reason that the blooms are always useful, especially during the winter and early spring months; therefore a few notes on their culture may be of some use to readers of the Domain.

The ground which is intended for the plants during the summer months should be manured and roughly dug at the latter end of autumn to let the frost get well into it. The beginning of May is a very suitable time for planting the runners, only using the side growths and securing with each a little root if possible. Well tread and level the ground, and plant them firmly at a distance of a foot between the rows and plants, giving a thorough watering after the planting if the ground be anyway dry.

During the growing season cut away runners and flower buds as they appear, and keep weeds in check by occasionally hoeing. Do not at any time let the plants want for water, giving at intervals some liquid manure; and if the weather be very hot during the summer apply a light mulching of Mushroom-bed refuse. It is a good practice during the growing season to lightly spray the plants in the evenings with a syringe or a fine-rose water-can when it has been hot during the day, as red spider is thus kept in check.

The time for lifting and placing in their flowering quarters should be the middle of September, so all preparation must be made in time to receive them. Some prefer planting in cold frames, but in my opinion they do better if a hotbed is made for them. Make the bed in time for it to settle and cool a little; it should consist of leaves and litter in proportion of three parts of the former to one of the latter, filling the frame to within a few inches of the glass, and when settled add about 6 inches of good soil. When the time, as before stated, has arrived for putting into the frames, give the plants a thorough watering if the ground be dry, cut them all round with a spade, keeping far enough away not to injure any of the roots, then carefully lift in order that they may have a ball of soil about the roots. In planting place them at a reasonable distance apart, according to the size of the plants, so that the air may pass freely between them, after which give a good watering with a rose water-can to settle the soil about the roots. The lights of the frame may be left off both night and day, but they should be in readiness if required, and in frosty weather also cover with mats. Remove all dead foliage from the plants, and all weeds as they appear, because if allowed to remain these will completely spoil them.—P. R.

STRAWBERRY FORCING.

PREPARATIONS are usually begun for the next year's supply of Strawberries as soon as the last dishes of fruit are gathered from the late forced or protected plants. A gardener's life is a regular round of preparations, and, as a rule, those who succeed the best are the ones who look ahead the farthest, and commence preparations a few days or weeks before the orthodox time.

One never hears of ripe Strawberries being provided too early, rather the reverse, so that there are three things that must be observed, and they are early runners, early potting, and early maturing. By securing these, a fourth can be found—early fruit. The runners should, therefore, be in their fruiting pots late in June or early in July; matured late in October, and carrying ripe fruit at the end of January, or very early in February.

Prompt potting is the first item of importance, and to have fruit at the earliest possible date the plants must not only be in their fruiting pots by the time named, but they must be stout and sturdy. In late seasons it is only those with vigorous young plants who will be able to have runners established in good time. Old plants do not produce runners as early as young plants, and they are not so vigorous or fine. The practice, therefore, of planting a bed of Strawberries annually in July is urged as excellent practice. The plants form early and good

runners, and also fine trusses for fruit. Runners, too, which are taken from young plants are not drawn in their early stages by a mass of surrounding foliage. This is a matter of importance, as if weakened and drawn during the first weeks after becoming plants they cannot form robust and fruitful crowns in the short season during which they must be perfected and matured. Runners, then, must be rooted early, under full exposure to light and air, so that they become dwarf sturdy plants, with the leaves spread horizontally, instead of tall plants with upright leaves and semi-bleached petioles.

There are various ways of rooting the runners, and with the object of gaining time and saving labour some growers peg them direct into their fruiting pots, on the principle of preventing a check by subsequent potting. This, however, is not considered the best plan, for two reasons—namely, the soil must be made so firm that the roots are not emitted freely and quickly; and because when the pots are necessarily spread over a large space of ground, watering cannot be done carefully, with the result that the soil in some pots will be too dry, and in others may become sour by extreme wet. It is better to layer the runners in small pots, of moderately firm but rich light soil, composed of equal parts of loam and sweet decayed manure, with an addition of crushed charcoal.

—INTERESTED.

(To be continued.)

HARDY FRUIT GARDEN.

Protecting Wall Trees. Although actual protection is not needed by Apricot, Peach or Nectarine trees until the blossoms expand, it is desirable that the material for doing so be in readiness and arranged so that it is readily available.

Protecting with Curtains.—When the fruit wall is provided with a coping of projecting wood or glass, there is something on which to hang the projecting material. This may consist of woollen netting, frigi domo, tiffany or canvas. Whatever material is used, brass or iron rings should be sewn to the upper edge, and then the curtains may be run on iron rods fixed on the front of the coping. This will keep it clear of the trees and enable it to be drawn on one side when not in use. It must be properly secured at the bottom, or it may be blown against the trees and do damage. The best arrangement is effected by means of an iron rod attached to short uprights fixed in the ground. Temporary security may be employed, and the blinds or curtains drawn up to the coping when not in use.

Pole Arrangements.—In the absence of a coping, long poles may be laid from the ground to the wall in front of the trees. On them stretch the protecting material, which may consist of canvas or tiffany. The material may be fixed on the poles, which should be movable, or the poles temporarily fixed and the protection removable. The latter is usually the better plan, but if netting is used neither it nor the supports need be interfered with.

Fish Netting.—It is very important that all protection should hang clear of the trees. If the ordinary stone coping projects sufficiently it may be enough to allow a double or treble thickness of fish netting to depend from it. Fish netting is good protection, and has the advantage of not needing removal until protection is no longer necessary. It admits light, and free ventilation is insured.

Other Means of Protection.—Branches of evergreen or deciduous trees may sometimes be conveniently used instead of more elaborate materials. Hornbeam, Birch, and Hazel of a twiggy character are thus employed, placing them behind main branches to hang over the blossoms. They should, however, only be utilised when it is impossible to protect with anything better.

Outdoor Figs.—Figs on walls may now be pruned and nailed. Thin out the shoots where they are crowded, and allow those remaining to be at full length. Where it is intended to plant young trees, the site should be well prepared and thorough drainage insured. A firm substantial soil is needed, one containing calcareous matter either naturally or introduced. Lime scraps or old plaster are good additions to soils deficient in lime. In the preparation of the soil avoid the use of manure, as it will cause growth of too strong character.

If maiden trees are planted, shorten the leading stem to 15 inches. One growth on each side may extend, these to be shortened the following year and two shoots allowed from each. Give them plenty of room so that lateral or side shoots may have room for extension, training them at full length. By shortening some of these each season, there will always be a supply of successional shoots for fruiting the following year. The old bearing wood ought then to be shortened closely in, to provide other young shoots, which if freely exposed to light and air become thoroughly well ripened and fruitful.

Strawberries. *Spring Planting.*—The planting of strong young plants ought now to be brought to a conclusion, especially with those which have no soil attached to their roots. Moved from one part of the garden to another, they can be lifted and planted without causing any check, but plants from other sources have to re-establish themselves; hence in planting, let the roots be carefully spread out, covered with soil and made firm, and if the ground is very dry, apply water.

Mulching.—The spring application of long littery and short manure combined may be commenced. The old exhausted mulching applied the previous autumn must be carefully raked off, removing at the same time deep rooting weeds and old discoloured foliage. Apply a liberal dressing of the manure, for by the time the fruit is ripe the strawy portion will have become bleached and clean, and the solid portion reduced in bulk by the washing into the soil of its soluble constituents.

Planting Fruit Trees and Bushes.—It is not too late yet to plant some of the smaller sized fruit trees, including bushes such as Currants and Gooseberries. These are usually well furnished with fibrous roots, and therefore move well and are soon re-established. Plant on previously prepared well firmed ground. Spread out the roots in wide holes. Stake and tie securely the standards, as well as others which need it. Lastly mulch the surface with littery manure. Prune the shoots half way back or more if weakly, selecting prominent wood buds.

Preparing Trees for Grafting.—The branches of large old trees shortened some time ago, should, just previously to grafting, be again cut back, so as to secure fresh clean portions of bark for the insertion of grafts. Smaller trees may have the head of the stocks sawn off at the time of grafting. Scions must be kept dormant in moist soil in a shady position until wanted.

FRUIT FORCING.

Cherry House. When the fertilisation of the blossoms has been effectual, the Cherries will be seen swelling at the base of the decayed flowers, then syringing may be resumed—once a day at present, and twice a day after the remainder of the flowers are cast and the weather is clear and warm. Artificial warmth will only be necessary to prevent the temperature falling below 40° at night, and to maintain 50° as a minimum by day. Ventilate at 50°, closing at the same, regulating the ventilation according to circumstances, but not allowing a rise above 65° without full air. If green aphides appear fumigate the house, and keep a sharp look out for black aphids, assailing it on its first appearance with tobacco water applied with a brush to the affected parts. The foliage must be dry when fumigation is practised. Keep a strict look out for grubs. Stopping will soon require attention. Pinch out the points of the growths when they have made 4 to 5 inches of growth, removing those shoots not required. Train extensions in their full length, also those for filling vacant spaces. Overcrowding must be strictly guarded against, it being prejudicial both to the present and future crops.

Peaches and Nectarines. *Early Forced Trees.*—An equable temperature is desirable during the stoning process. With too much heat at night the trees are deprived of rest, and this is not favourable to the fruit; cold and drying draughts in the daytime are even more injurious, a sudden change sometimes proving fatal to the crop. Continue the night temperature at 50° to 55°, also in dull weather in the daytime, but 70° to 75° with gleams of sun, ventilating from 65°. Attend to thinning the fruit betimes. It is not advisable to leave, during the stoning process, more than twice the number of fruits that are to remain for the crop. One fruit to each square foot of trellis covered with foliage is ample for the large Peaches, and the medium-sized varieties may be left a little closer. Nectarines being smaller than Peaches, are often left much too close, which reduces the size of the fruit proportionately, whereas to secure fine fruits they require thinning similar to Peaches.

Secure all the shoots required for extension and next year's bearing to the trellis as they progress, stopping any gross successional growths at a length of about 15 inches. If the stopping results in laterals pinch them at the first leaf, and so on as produced. If extension is wanted the uppermost laterals may be trained in. Pinch laterals on extensions to one leaf, and succeeding growths to one joint. If the trees are in good order there will be little necessity for stopping the shoots if they are allowed space for development of the foliage to solidify the wood as made. Shoots retained to attract the sap to the fruit should be stopped to one leaf, they having previously been pinched in the first growth at the second or third leaf. Avoid stimulating the trees while stoning, but afford due supplies of water and food of a phosphatic rather than nitrogenous nature.

Second Early Forced Trees.—Proceed with disbudding, a shoot being left at the base of the present year's bearing wood or last year's young wood, and one on a level with or above the fruits. The first must be trained forward, but the latter should be stopped at the second or third leaf. Upon extensions leave young shoots at 15 to 18 inches distance, the growth from the extremity being trained as a continuation of the primary branch. Commence tying early, as when the shoots are allowed to grow considerably they cannot be brought down without danger of breaking. Overcrowding must be carefully guarded against; it is fatal to fine highly coloured fruits and the formation and perfection of the wood for future crops. Thin the fruits by degrees, leaving those well placed upon the upper side of the trellis in sufficient quantity for a crop, or a little more, until the final thinning before stoning. In no case is it good practice to tax the trees with superfluous fruits after they are the size of marbles. A temperature of 55° to 60° at night, 65° by day, increasing to 70° to 75° is suitable.

Houses Started at the Beginning of February.—The trees in these have set their fruits, or nearly so, and recourse must be had to syringing in the morning and afternoon of fine days, but an occasional sprinkling, with damping the house, will suffice in dull weather, always having the foliage and young fruit dry before nightfall. Disbudding must be done gradually, commencing with the most forward growths, also thinning the fruits after it is seen which take the lead in swelling, removing the smallest first, but avoid large reductions of foliage or of fruit at one time.

A temperature of 55° at night, 5° less on cold mornings, 55° to 60° by day, advancing to 65° or 70° with gleams of sun, will bring the trees on sufficiently fast, ventilating from 55° or 60°, and not allowing an advance above 65° without full ventilation.

Houses Started Early in March.—With the flowers expanding syringing the trees must cease, for there is danger, especially in dull weather, of weakening the blossom and converting the pollen into paste. An occasional syringing may, however, be practised if the weather be unusually bright, and the atmosphere dry. Damping the floors and borders is generally sufficient, and a safer plan. Admit air freely in mild weather, and fertilise the flowers on fine days. Maintain the night temperature at 45° to 50°, 55° by day artificially, and 65° from sun heat. Admit a little air constantly, increase the ventilation at 50°, and give more as the heat rises, having full air on at 65°, closing at 50°. Superfluous flowers on the under side of the shoots may be removed by drawing the hand down the growth.

Late Houses.—Where the roof-lights have been removed they should be replaced at once, the buds being well advanced in swelling, and promising an abundant crop of fruit. If there be any trace of aphides apply an insecticide, or fumigate the house before the flowers expand. Nothing conduces more to a good set than removing the flowers on the under side or back of the trellis, and turning on the heat after the anthers show for a short time in the early part of the day to advance the temperature to 50°, and to permit of ventilation, as if there is a prevalence of dull cold weather at that time, closing the ventilators for safety prejudices the pollen. Houses that have fixed roof-lights must have the borders rendered thoroughly moist.

THE BEE-KEEPER.

PAINTING THE INSIDE OF HIVES.

At this season, probably more than at any other time, there are numerous empty hives in the apiary. This may arise from a variety of causes, and not necessarily through loss of stocks. If only a few colonies are kept there may be only a solitary empty hive on hand, whereas in a large apiary they may be counted by the dozen owing to the preparation that has been going on throughout the winter months in anticipation of an increase in stocks, but in either case their treatment should be the same.

Painting the inside of the hives with ordinary paint is not recommended. Stockholm tar and carbolic acid is what we have used with great success for several years past. We first operated on one hive which had been in use for several years, well working the mixture into all the crevices, the whole of the interior of the hive being done in this manner. This had the effect of destroying all insect life, and was of no detriment to the bees. The mixture should be put on whilst it is boiling, and is best prepared by placing the Stockholm tar in an open vessel over a clear fire; an old saucepan answers the purpose admirably. Add as much carbolic acid as will make it thin enough to be put on with an ordinary paint brush. Care must be taken that it does not boil over, or it will at once be in flames. Should it do so lift the vessel containing it off the fire, and place a flat piece of slate, or something similar, over the top, and the fire will be instantly put out. The carbolic will evaporate at a rapid rate, and it will be necessary to add more should the tar be too thick to work in readily.

It is more important to use this composition on hives that have been in use for several years, and it is not really necessary to treat new hives in the same manner; still, as it cannot possibly do any harm, it is an advantage. After the hives have been well dressed over place them in the open air for a few days and the smell will completely pass away. It sweetens the hives in a marked degree. Bees, too, appreciate it, as it is quite a common thing to see them alight on the hives the same day they have been placed in the open air. Although dozens of hives have been treated in the above manner, the bees have always taken readily to them; in fact, to judge from the manner they have worked after being placed in one of these hives, we are inclined to think they prefer them, as they are quite sweet in less than a week after being painted. We therefore have no hesitation in recommending all bee-keepers who have not tested the plan to give it a trial, and it cannot have anything but a beneficial effect on the bees. How often one hears of diseases, real and imaginary, of bees in various parts of the country! There would, however, be less cause of complaint if all the hives in the apiary were treated as above.

ENTRANCE BLOCKED BY DEAD BEES.

We are convinced many bee-keepers make a mistake in reducing the entrance to the hives too much. Now that the sun is gaining power daily they forget how important it is that the bees should be able to pass in and out of their hive freely. During the prevalence of bright sunshine and a high temperature quite recently, our attention was called to a hive in which there was great excitement among the

bees. At first we thought it was a case of robbing, but on a closer examination we found the entrance was blocked with dead bees. Instead of the entrance being half an inch or more in depth, it was less than two-eighths; this was caused by a projecting piece of wood. The consequence was the bees in their anxiety to leave their hive became suffocated, and there not being sufficient space to bring the dead bees outside, they blocked the entrance, and many bees were lost in consequence. The hive was at once placed on a dry floor board and the entrance opened its full width. But this did not allay the excitement. The front of the hive was then slightly wedged up about an eighth of an inch. This had the desired effect. Since then the bees have been working freely, and are probably now little the worse. Fortunately it was found out in time.—AN ENGLISH BEE-KEEPER.

•• All correspondence relating to editorial matters should, until further notice, be directed to "The Editor," 8, Rose Hill Road, Wandsworth, S.W., and NOT to 12, Mitre Court Chambers, Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *nom de plumes* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Growing Cucumbers and Melons in the Same House (*Inquirer*).—When a span-roofed house has the ends east and west, and Cucumbers and Melons are to be grown in it, the south side is the better for Melons and the north for Cucumbers. Such has been our experience, and we have tried them both ways, and singularly under the same conditions as obtain in your case. The plan you propose was not with us a success, but hardly a failure. We advise the Cucumbers being given the north side; they will do splendidly on a hotbed planted in soil. Melons cannot have too much sun, therefore give the position where they will receive it in full measure.

Making a Vine Border (*Idem*).—Vines like ferruginous or irony soils, and they also must have lime, magnesia, and potash. Lime you will supply in the old mortar, and both potash and magnesia with lime in the wood ashes. As the soil is not fibrous, broken paniles will be useful in keeping it open, but we should have preferred burnt earth; the crushed bones will yield phosphoric acid and some ammonia. We should add some charcoal and also horse droppings; the latter to ammoniate the iron, and the former to keep the materials open and sweet. With the drainage complete and the materials fairly proportioned, we do not see what more could be provided to make Vines flourish.

Cucumber Roots Knotted (*B. B., Novice*).—The plants are affected in the roots and root stems by root-knot celtworm, *Heterodera radicola*. The plants, if like those enclosed, are past remedy, the root stems being seriously affected. You may, however, water them without delay with a solution of soluble phenyle (Little's), 1 fluid ounce to 3 gallons of rain water, giving as much as in an ordinary watering. The watering can be repeated in about a week, but we fear there is little chance of saving the plants. The best preventive is to scald the soil and every part of the house in connection with the bed, this part being thoroughly done. We use soluble phenyle at double the strength given above for disinfecting purposes. It answers well, operating ten days or more before planting. Another plan is to mix through the soil, some time in advance of using, 1 lb. of a mixture of equal parts by measure of air-slaked lime—dry and floury—and soot, and half-pound of kainit per square yard of 1 foot depth of compost, mixing evenly, and turning over at least once, say at an interval of about a week. The house-bed, floor—everything—should be thoroughly scalded before placing in the prepared soil.

Plants for Back Walls of Vineries (R. L.).—We do not know of any plants better suited for the back walls of vineries than Camellias, which you mention. They will succeed well in the border 18 inches wide and deep, only take care to provide ample drainage. The compost must be rough—that is, fibrous, tearing up and rejecting the fine. It is also advisable to use some charcoal in the compost to keep it sweet, and sharp sand liberally to insure porosity.

Lasiandra, or Pleroma macrantha (T. P. Bridge).—Cuttings of half-ripened shoots root readily in a close frame in the stove at almost any time of year when they can be obtained, but the summer is the best. The plant thrives in a compost of three parts turfy loam and one part leaf soil or well decayed manure, with one-sixth of sharp sand, and about half as much of charcoal. It does not require a large amount of root room for the size of the plant, which is of a somewhat straggling habit, and for covering a pillar or a rafter in a cool stove is one of the most beautiful plants we have. It flowers most profusely when in a large state. A season of rest should be allowed in winter, but not so as to cause the leaves to fall, affording plenty, but not an excessive amount of water during the summer. It should be cut in, if at all, after flowering, this taking place in the winter time.

Pruning Variegated Box and Yew (O. F.).—The Variegated Box may be cut in as much as you like and it will break again; likewise the Variegated Yew, operating in either case towards the end of April. In neither case, however, is it desirable to remove more than irregularities of growth, so as to secure symmetrical and evenly balanced bushes where there is room for them to grow. Our remarks had reference to overgrown bushes, and if yours are such cut them back as much as necessary and they will break again and form compact growth, and afterwards they may be clipped annually if so desired. See page 228 for reply to your question on poultry.

Removing Rhododendron Flower Buds (Idem).—It is an excellent practice to “nip” off the flower buds before flowering when the plants are weakly, but better still to give them a top-dressing of cow manure, not too fresh or more than half decayed. It gives a deep green colour and freer growth; indeed, it is poverty the plants are suffering from. The best time for pruning old branches is the end of April during moist, mild weather.

Seakale Beds (N. B.).—The beds should be prepared without delay, stirring the ground deeply and manuring liberally. They must be 4 feet wide with 2 feet alleys between. Select one-year-old plants, place three triangularly in a patch 1 foot from each side of the bed and 2 feet from patch to patch, and the three plants in each exactly 6 inches apart. Plant so that the crowns are just level with the surface. You will then have two rows of plants in patches 2 feet every way from centre to centre in a bed, and the planting should be done at the end of March or beginning of April. If kept clean and not allowed to flower they will form crowns for forcing on the ground next winter. Seeds may be sown if you prefer in rings 6 inches in diameter, making the drill an inch deep, and in this place the seeds 3 inches asunder and cover with fine soil. When up and growing freely remove all but three plants in a patch, always retaining the most promising. The seed should be sown early in April. The plants may be forced next winter.

Forcing Roses (B. S.).—It occurs to us that when you say your “Maréchal Niels suffered from anticipation of proper root action,” and the fact that the plants are growing in side borders of your Rose house, that you mean the wood was excited by artificial heat before the roots could supply enough sap to keep the growths going freely. Strong growing Roses planted in side borders will soon have a large number of their most important roots in the soil outside of the house. We think you omitted to cover this with a good protection of loose litter, such as heather, gorse, or even mats, which would be a great help when starting the plants early in January. We have carefully considered your difficulty, and also reperused the replies, and can now think of no other probable cause. You cannot expect roots in cold, and possibly frozen ground, to keep pace with the other part of a plant that is in a temperature of from 13° to 22° above freezing point, and more especially so in the case of several degrees of frost outside, which we so often get at the date you commenced.

Age of Lily of the Valley Crowns (Subscriber).—It is somewhat difficult to tell the age after the crowns attain to flowering size, but a one-year-old crown has no ring below the bud, though it generally shows where the leaf sheaths have girdled. As you are no doubt aware, crowns are formed on the runners or underground wires without any top growth, hence, as there were no leaves there could be no leaf sheath rings. Some call such a one-year crown, because it has been formed in the previous year, but it is only an adventitious bud. This the following summer will produce leaves, nothing else, and if examined in the winter will have a distinct ring on the root-stem just below the bud or crown. It is properly but one year old, though often called two, and may or may not produce flowers the following season. If left alone or transplanted it will give another ring on the root-wire as in the preceding season, but higher up—that is, nearer the crown, which has advanced accordingly. It is two-year-old as clearly indicated by the two rings corresponding to the respective years' growth. Such two-ringed crowns will usually flower strongly the following season, either indoors or outside. If the latter, it will again form another ring, and so on year by year indefinitely. Now for your specimens. No. 1 range in our opinion from five to seven years old, and have apparently been weakened by flowering in previous years. No. 2 appear from three to five years old, but only one the latter, and they have not been weakened by flowering in former seasons.

Specimens—Rhubarb (Young Gardener).—The Crotons were all dead and unrecognisable, due entirely to misdirection. Rhubarb is neither a fruit nor a vegetable, but when exhibited is frequently classed as a “fruit” because its stalks are used for tarts, pies, and puddings, never in any form cooked as a vegetable. Please read rules above before sending again.

Conifers not Healthy (Scotland).—The spray certainly shows no trace of ill health. We should confine any pruning to shortening straggling growth, so as to impart symmetry and compactness. Nothing answers better for these trees than a top-dressing of turfy loam with one-third of leaf mould or old cow manure, not applying more than a couple of inches thickness from the stem outwards as far as the branches extend. Now is the best time for cutting away dead branches, or if frosty defer until April.

Growing Mushrooms in Trenches (W. F. G.).—There is no book that treats separately of this mode of culture, but the directions given in “Mushrooms for the Million” could be easily adapted. There have been several contrivances for doing away with glass for growing Cucumbers and Melons. The transparent papers we have seen in use have not been very satisfactory. Perhaps we have not seen the improved article. Inventors should advertise, or perhaps some correspondent will give readers the benefit of their experience.

Watercress in Boxes for a Pool (Constant Reader).—Watercress may be grown in boxes, but preferably in pans, which are less liable to get out of order than wooden boxes. Whether boxes or pans are used they should have openings at the bottom, and be drained similar to those for land plants with potsherds, placing in from 4 to 6 inches depth of good loamy soil. Well rooted young offsets should be planted about 6 inches apart, and the boxes or pans so placed in the water that their edges or soil will not be covered with water more than an inch or two. The green-leaved variety grows the freest, and we think harbours most insects, but the large brown-leaved is the best in flavour.

Anemone (X. L.).—The Anemone flower appears to be one of the many varieties of the Chrysanthemum-flowered called Chapeau du Cardinal, the tubers of which may be planted early in October, about 6 inches apart and 3 inches deep, when, the varieties being mixed, they make a splendid display. After flowering, the tubers should be lifted, dried, and stored away in a cool place in sand. For flowering in pots they should be potted in September in a compost of two parts turfy loam and one part leaf soil, with a sixth of sharp sand. Place in a frame and introduce to heat—a greenhouse temperature—in November or December. We are not aware that it can be had in flower in January, but it is well worth trial.

“Fever Fly” on Lettuce Root Stems (J. A.).—The flies are certainly a species of Dilophus. The legless grubs accord with those of *D. vulgaris*, only they are larger, as also are the flies. The only way to make certain of the identity of the fly would be to rear some of grubs and have the flies from the pupæ cases. No doubt the manure would favour the fly in a dry season, but we have had no experience of the kind, though suffering from the attacks of the lesser or spotted crane fly, *Tipula maculosa*, to a serious extent. For this we found a dressing of gas lime advantageous, and it acts well on Dilophus, which in the larval state bears a close resemblance to the grubs of the smaller crane fly larvæ, but is not more than half the size. The preventives given in the issue of February 16th are the most successful we have tried.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (J. P.).—*Galax aphylla*. (T. H. B.).—The light coloured flower is *Orchis tridentata*; the dark one is *Orchis longicorn*. (H. M.).—1, *Acacia cordata*; 2, a *Euonymus*, probably *latifolius variegata*, but specimen rather too small for positive identification. (A. W. P.).—1, *Libonia floribunda*; 2, *Cymbidium eburneum*; 3, dead, 4, *Euonymus radicans variegata*. (V. B.).—1, *Celsia cretica*; 2, *Iris fimbriata*; 3, *Anthericum variegatum*.

FIELD CABBAGE.

In these days, when the return of low prices for corn makes the farmer turn again to his live stock to help him through the wood, the question of sound and economical food is a serious one.

Prices of dry adjunct foods, cake, offal, corn, and grains or culms, have been very high, or at least high as regards prices to which we have been recently accustomed; it is therefore more than ever necessary to make the land produce its best—i.e., the best of which it is capable in the shape of food for man or beast. Food for man is Wheat, and the price at present being 27s. per quarter, it is easy for every farmer to estimate the profit or loss on growing an acre of Wheat.

But what is the best food for live stock? We answer without hesitation, "Cabbage." A good plot of Cabbage is never without a useful purpose; with a succession of Cabbage from midsummer to Martinmas the flockmaster need have little anxiety as to the welfare of his sheep. Some people object to the Cabbage crop as being an expensive one; so it is, but good things are not usually acquired without cost, and an acre of good Cabbage will feed twice as many sheep as an acre of Turnips, in addition to being much more

digestible, and therefore better calculated to keep the animals in a healthy condition.

Any moderately good soil will grow Cabbage, but we should not recommend light sandy land as being likely to grow a satisfactory crop. With good land, however, there is every necessity for high cultivation. It is almost impossible to overfeed Cabbage, but at the same time it is useful to know what manures have the most telling effect in proportion to the cost.

For July and August use the seeds should have been sown (the first week of the previous August and planted out about November 1st. For later use the seed may be drilled early in April, at the rate of 3½ lbs. per acre, and for succession as late as May 14th. The previous preparation of the land is important; it must have been well worked and got as nearly to the state of a good Turnip mould as possible. Any requisite cleaning should have been done in early autumn, then twelve to twenty loads of farmyard manure should have been ploughed in if possible 8 or 9 inches deep.

The spring stirring will possibly bring some of this to the surface; but it does not matter, as the last ploughing will again bury it. A few days before drilling the land should be ploughed about 4 or 5 inches deep, then well harrowed and rolled, and the sowing completed at once.

As noted above, good soil and plenty of manure are the first two requisites for the growth of Cabbage; but, as we have before remarked, the crop is one that can hardly be overdone with kindness, and the use of suitable artificials will not only bring an increased yield of produce, but materially help succeeding crops; for Cabbage is really, when, as is so often the case, carted away for use on grass, an exhaustive crop. The immense weight of succulent food, though calculated to benefit the land on which it is consumed, must tax the resources of the land on which it is grown; therefore it must be liberally treated, so as to benefit materially the present crop and leave the land in condition to produce paying crops in the future.

We should not advise the use of any large quantity of phosphatic manure, as it will not be necessary in addition to the phosphates contained in the natural manure, and we should prefer to save the phosphate and apply it to the succeeding crops as needed.

Ammoniacal manures, such as nitrate of soda and sulphate of ammonia, if used judiciously, can be used with good financial results; but, strange as some people may think it, the use of salt with the ammonia has been found to give a great increase of Cabbage. Whether used with nitrate or sulphate, salt has been found much more valuable than phosphates; whilst the latter had very little appreciable effect, the result of using salt was most markedly and satisfactorily apparent. The effect of kainit was only in proportion to the amount of soil therein contained.

Given a good supply of yard manure, we should recommend in the way of artificials 3 cwt. superphosphate, 3 cwt. salt, and 1 cwt. sulphate of ammonia per acre, sown broadcast and harrowed in before the seed; 1½ cwt. nitrate of soda sown broadcast immediately after the plants are singled out.

One great point in the growth of Cabbage, as in that of all root crops, is the constant use of the horse or hand hoe; the surface must be kept stirred until the plants begin to take full possession.

There is an idea, and it is a very prevalent one, that stirring the surface assists evaporation and adds to the ill effects of a drought. The opposite is really the case, for to prevent evaporation the land must not be allowed to crack, and to prevent cracking constant movement of the surface soil is the only remedy.

Having got a Cabbage plant, then we must keep the skerries constantly at work and the hand hoe working between the plants. When the plants begin to get large enough to make such work difficult, stop it and leave them in undisputed possession.

WORK ON THE HOME FARM.

In some of the colder districts, such as the high wolds, much spring corn has been sown and has gone in satisfactorily. We ourselves, being on warmer soil, have waited for the nearer approach of Ladyday, and

now find considerable hindrance to the continuous progress of the drill owing to the severe night frosts. Strong white rimes, with ice an inch thick, have such an effect on the land that even March sunshine cannot soften it until afternoon, so that less than half a day's work at drilling is really possible. We are struggling on, however, for the soil has become fairly dry, and the seed will be better in the ground than in the granary.

The lambing is proceeding with varying results; as a rule there is a small loss of ewes, but the crop of lambs leaves something to be desired. We hear of one or two serious cases of loss amongst the ewes which are difficult to account for, roots certainly not having been abnormally plentiful this year, whilst the season has been mild, and there have been no frozen Turnips.

The very early lambs have done very well and will be soon ready for slaughter. One sees so many early lambs about nowadays that they do not realise the price they did a few years ago; the early lamb breeder having been observed catching the worm (in the shape of 1s. 3d. per lb. for lamb), and having had in consequence many imitators.

The young cattle are doing very well, quite fast enough, for now we have so many hours' sunshine they may easily be overdone in the matter of food; they must not be kept too closely housed, but allowed half a day's run in the open yard, and in a week or so a whole day, and so gradually hardened for turning out.

But, alas! the frosts have not only nipped the young grass shoots, but discouraged the immediate growth of more, so it is soon enough yet to talk of turning out.

We were just in time to get the Wheat rolled before the frosts set in; notwithstanding the cold nights the appearance of the plant is greatly improved, and a good rain would produce a more marked advance. As a rule Wheat is not so forward, and does not look so well as last year.

We have occupied the mornings with cross-cutting the fallows, but have not been able to work any of them yet: fortunately little remains to do in the way of cleaning.

THE NATIONAL POULTRY TEST.

It will be in the recollection of most agriculturists and other poultry keepers that the above test commenced on the 1st of March, 1898, and closed on the 1st of this month. As considerably over one million prints of the test circular were distributed through the post and press columns, it is hoped that a large number of results will come to hand during the next week or two, and which I hope to tabulate and publish later on. As considerable public interest and expectation exists as to these returns, perhaps you will allow me to give particulars of the first received as it will be of special interest to poultry keepers who are obliged to restrict the range of their poultry to very narrow limits.

The success obtained by the flock of fowls in this return confirms the last paragraph of the poultry test circular, in which I said:—"My thirty years' experience in poultry keeping leads me to believe that results will be forthcoming from these tests calculated to both astonish and impress."

GLOUCESTERSHIRE.—Results obtained from 1st of March, 1898, to 1st March, 1899, from twenty hens confined within a yard 36 yards by 16. Yield of eggs:—March, 424; April, 446; May, 441; June, 444; July, 372; August, 308; September, 236; October, 182; November, 200; December, 143; January, 222; February, 291. Total, 3709.

Contra	11 13 4
Profit 10s. 1d. per head					£10 1 8

NOTE.—As it is necessary that certain items should be common to each balance-sheet to fairly compare one return with another, I have fixed the price of each flock of fowls subjected to the test as though they were purchased in at 3s. per head at the start and sold out at 2s. 6d. at the close of the year. I also fix a common price for roosting the fowls in a wooden house at 30s. for twenty head or £2 for forty head, and the value of the manure at 15d. per head or £1 10s. per ton. The labour question is also dealt with upon the same lines. Attendance on each field poultry house

at a distance from home six hours per week; and homestead houses at three and a half hours. Lads' wages 11s. per week. The above prices are as fair an average as it is possible to fix, to compare the true merits of the different birds tested and profits realised.

The somewhat high average price obtained from the above yield of eggs is accounted for by the facts (1) close proximity to a town market, (2) large size of eggs, (3) large number laid through the winter months. The cost of purchased food, it will be seen, is returned at about 1d. per head per week, but this was augmented by certain kitchen refuse which would have been otherwise wasted. This scrap refuse from a family of six no doubt much conduced to the laying properties of the flock, which attained the high average of 170 eggs per head, and this, after deducting 300 eggs as the estimated yield of the ten pullets reared and which laid through the winter.

I trust that the highly satisfactory profit of 10s. 1d. per head shown by this return will encourage many poultry keepers to forward me their balance-sheet, although they may not have kept their stock strictly upon the poultry test rules.—K. B. DE LA BERE, *Burbage Hall, Hinckley*.

P.S.—The accuracy of the above return may be relied on. The eggs were recorded daily and the invoices of food purchased carefully filed. Let me, however, warn enthusiasts who, after reading the above, think that by setting up twenty hens they may attain equal success. This may be possible, but is highly improbable. A profit of 5s. per head is seldom exceeded with flocks of forty head, although 8s. per head is often realised where only a dozen or so are kept under favourable circumstances.

OUR LETTER BOX.

Poultry (O. F.).—As the buff Orpington is, so far, the nearest approach to the combination, in one fowl, of more than mediocre table and laying qualities, we would certainly not advise the introduction of an Indian Game male to a pen of buff Orpington hens. The progeny of such a union would have broad breasts, but the flesh would be coarser and the hens very indifferent egg producers. Of course Indian Game-Dorkings are the largest table fowls, the breast receiving breadth from the former breed and depth from the latter. Whether, however, such fowls are of the finest quality is a matter of opinion and a subject that is frequently debated; albeit, if properly finished, they sell readily, and at remunerative prices, in the London and several provincial markets, where the chief desiderata in a table fowl are abundance of breast meat, white flesh and legs, and small offal. The flesh of buff Orpingtons is beautifully white and of excellent quality, characteristics which command for the fowls free disposal in almost any market. We have not personally worked Procter's "Reliable" incubator, but it is reputed an excellent machine. Provided the male bird is vigorous, six hens may, in a confined run, be permitted to run with him at this season. Fowls under such conditions require careful and unremitting attention. Several things conduce to "chicks dead in shells" in incubators. One of the most common are weak germs, owing to the fowls from which the eggs were obtained being immature. Another frequent cause is the retention of eggs for too long a period before they are placed in the machine. If satisfactory results are desired with incubators the eggs used should be as fresh as possible. Vibration is also accountable for many dead and crippled chicks, therefore no better place for the successful working of an incubator could be utilised than an ordinary cellar. Much valuable information regarding the management of incubators is at the present being published by our contemporary *Poultry*.

REMARKS.

5th.—Bright sunshine throughout.
6th.—Fog early; sun from 9 A.M., and bright night.
7th.—Rather dense fog till 10 A.M., bright sunshine after.
8th.—A little fog early; alternate cloud and sun during day; rain at 11.30 P.M.
9th.—Rain till 3 A.M. and spots of rain at 10.15 A.M.; sunny at times in morning; bright afternoon and evening.
10th.—Bright sunshine almost throughout.
11th.—Overcast and humid.
Another fine week, not so cold as the previous one, but the minima still low.
—G. J. SYMONS.

A FEW SPECIALITIES.

Barr's Monstrous Long Pod Broad Bean.—The earliest, best flavoured, largest podded, and most productive. Per quart, 2/6.

Barr's Green Haricot Dwarf French Bean.—Of very delicate flavour, and unsurpassed as a Haricot Bean in Winter. Per quart, 2/6.

Barr's Best of All Autumn-cutting Cabbage.—Dwarf and compact, very early and of exceptionally fine cooking quality. Per packet, 6d.; per oz., 1/6.

Barr's Earliest French Short Horn Carrot.—A favourite for soups, and extremely early; the best variety to sow in frames. Per packet, 4d.; per oz., 10d.

Barr's "Pride of the Market" Cucumber.—A specially fine dark-green variety of handsome shape; a favourite in Covent Garden Market. Per packet, 1/6.

Barr's Long Keeper Onion.—A fine handsome Onion, and a very long keeper. Per packet, 6d.; per oz., 1/3.

Barr's "First of All" Radishes.—Scarlet or white, fine little, short-leaved, very early Radishes. Per oz., 6d.

Barr's Early Ruby Tomato.—Bright scarlet solid fruit of fine form; an abundant cropper; the best FIRST EARLY Tomato. Per packet, 1/6.

Barr's Thick-fleshed Tomato.—Surpasses all other varieties for depth of fruit, solidity of flesh, high quality, and heavy cropping. Per packet, 1/6.

BARR'S SEED GUIDE (Free) contains a full descriptive list of the best Vegetables and most beautiful Flowers, with many Practical Hints on Culture valuable to Gardeners, Amateurs, and Exhibitors.

COVERING VINE BORDERS.

IN my opinion there is a decided objection to covering outside Vine borders, as being injurious to the health of the Vines. My reason for penning these notes is because I think that by recording my experience in this matter it may possibly be the means of economising labour in gardens where it is none too plentiful, and at the same time bring about a larger yield of fruit of improved quality.

In my younger days I followed the example of my elders, and men who had more experience, and annually covered the outside Vine borders in my charge with quantities of leaves and partially decayed manure to keep them in position. Previous to applying the leaves and manure some 3 or 4 inches of the surface soil was removed, and in place of it was substituted an equal quantity of fresh fibrous loam and decayed manure.

Upon examining the borders in spring after the removal of the covering it was found that there were fewer healthy roots than in the previous autumn, and this decay was attributed to the sodden condition of the border brought about by the covering preventing the admission of air to the soil. Whenever there is a quantity of fermenting material placed upon a Vine border it may cause the production of thick fleshy roots, which decay on the removal of the covering, and this leaves the Vines in a worse condition than if such roots had not been produced.

When a statement is made to me that is at variance with recognised custom, I invariably inquire what proof can be adduced in support of it, and the question may properly be asked: What proof have I to offer in support of my statement that Vines are benefited rather than injured by leaving the borders fully exposed to the influence of the weather?

After due consideration, and a certain amount of anxiety, I decided, in the autumn of 1879, to dispense with the orthodox winter treatment of outside Vine borders. A better season for testing the advantages or otherwise of the system could not have been chosen had the

They were not more than 18 inches in the elevated above the level of the surrounding not only penetrated from the upper surface, but from every direction.

year, 1880, the buds burst into leaf more freely in previous years, and the Vines carried a good which shanking was entirely absent. Had the destroyed the result would have shown itself either smaller berries, or in shanking, but none of these the experiment here mentioned I have never outside Vine borders during the winter months, to do so in the future. Subsequently I have of Black Hamburgh Vines—which ripened the of May—in the same way, with satisfactory

Vine roots, in soil of suitable texture and in good hardy, and are in a much better condition supporting the Vines in a vigorous growth placed in a position where artificial heat is generated the year when comparative rest should be gained, where the material is exhausted by fermentation prevents air and the heat of the sun from reaching thereby elevating the temperature at a time when it

W. NEILD, *Holmes Chapel, Cheshire.*

ASPARAGUS CULTURE.

commonly adopted for the formation of Asparagus planting roots, and raising from seeds. Both have as and are equally worthy of consideration. The undoubtedly the quicker, and is therefore preferable sired as soon as possible. Where this is not the and for succession, seed sowing is recommended sure way of producing lasting results. At the remembered that as the Asparagus is to be a permanent to begin with is often economical. A free open chosen with a porous sub-soil. Stagnant moisture to Asparagus, and if it exists draining must be With a deep fertile loam to deal with, trenching a dressing of half-decayed manure to the subsoil of medium into a good friable condition. If the tive nature, a favourable opportunity should be enter for another breaking up and the incorporation such as road-scrappings, coarse sand, or lime a dry workable condition at the end of March, a roughly decayed manure may be dug in about a the surface be broken up and made smooth prepara-

that a decision must be arrived at respecting the the bed. Asparagus beds vary in this respect, has proved the success of a particular method is ing it. A convenient width for the beds is about alley of 2 feet between each. All cutting and can then be performed from either side without s. A suitable day, when the ground is moderately d to be chosen for sowing, and a 4 foot bed will

wet and inferior, to grow Asparagus courting failure; therefore, to grow Asparagus unsuitable for it special care must be given to the beds. Begin by marking out the ground where and remove the top spit of the best soil. A coating material may be placed on the subsoil after broken and then prepare a compost for the make up of consist of the soil taken out, with free additions of scrapings, sand, turf, leaf mould, lime rubbish. When this is spread evenly on the drainage it will be 6 inches to a foot above the ordinary level, which will Seeds may then be sown on the lines indicated above able to obtain a quicker return the planting of is preferable. The middle of March is a good time for Asparagus, and roots which are young and vigorous better returns than those obtained from old and plantations.

The planting may be done in rows in the same for seed sowing. The roots should be deposited in the rows, and the crowns be covered with soil. Failures with transplanted Asparagus may be due to the condition of the roots than to any other cause should they be allowed to become dry through exposure, and if obtained from a distance the sooner from the packages to their permanent quarters the planting is completed smooth over the surface with of good manure, as this will serve as a protection to which, after transplanting, are liable to suffer from

In addition to the annual dressings of animal manure benefited by the judicious applications of other manures undoubtedly good for the crop, and in coast districts seaweed are given with excellent results. So common this custom of salting Asparagus beds become tedious without a thought as to the conditions, and little harm than good by making the medium "soapy" is best applied when growth is commencing in the dressing. Occasionally light dressings of nitrate of soda during the cutting period are beneficial, but after then they should be stopped. Liquid manure from the farmyard applied during the first stages strong growth, and stout stems are invariably the good crowns. When under good cultivation the the to the time over which some beds last, and ill-effects often be seen in old-established gardens, where the often considered to be as much a permanency as the Asparagus. There is no great variety in the vegetable, and the most common are Early Argenteuil and Connoyer's Colossal.—C

ORCHARD SPRAYING IN NOVEMBER.

HAVING been asked by a farmer friend to write on this subject, and as the present is an opportune time, I am hoping there may be useful suggestions to farmers.

Potash Spraying.—This, to clean the bark of trees and to destroy insects lodging in the crevices, is done in Canada about April, whilst the snow is still on the ground, the buds open. For this purpose $\frac{1}{2}$ to 1 lb. of caustic potash to 1 gallon of water is employed. The mixture is mounted in a cart or low waggon, the men are provided with macintoshes to protect their clothes, and in some cases a cover over the horse; the Apple trees are sprayed on the trunks only are to be washed, this is done at

is used for caterpillars and other chewing
an equal part of lime should be added to
acid which may exist in the Paris green ;
to 40 gallons of water. The pumps are
casks holding 40 gallons, and are drawn
on a low waggon with a cranked axle.

the Bordeaux mixture is to take a 40 gallon
suspend in it 40 lbs. sulphate of copper in a
the solution a strength of 1 lb. to 1 gallon.

plants. Both the "single" and "pair" plants can be st
or bed, where the height of the structure permits, and
they can have an unobstructed light.

Boxes are preferred by some growers to pots, as not b
to breakage, more plants can be grown in a given space
not require so much water. All kinds of boxes are utilis
Tomatoes, both indoor and outdoor. A box 12 inch
8 inches in breadth, and 6 inches in depth, all inside me
about the smallest size I have seen used for a single pl

to the trellis. The boxes are handy for placing on wooden stages at the sides of span-roof or other structures, thus utilising them for Tomatoes in summer without interfering with the arrangements for plants in the winter. With the plants 2 to 3 inches from the sides (there are no ends in a square box), stakes can be placed outside, so that plants will be trained about 15 inches apart, allowing proper space between the boxes.

Boxes 3 feet long, 1 foot 6 inches wide, and 1 foot 2 inches deep, are hardly portable when occupied with plants. They are serviceable for placing at the end of a Cucumber house, or along the sides of structures in continuous order for plants to be trained to trellises. Single plants can be put in 15 inches distance, and fast or strong-growing varieties 18 inches, or the plants introduced 18 inches asunder on both sides of the box on "opposite vacancy" order, the outer plants, or those next the side of the structure, being trained to wires about 8 inches from the glass, and the inner ones to a trellis a foot lower. If stood at the ends of houses four pairs of plants may be placed in a 3-foot long box, or even five pairs for early work, arranging them conveniently for staking outwardly on each side.

After a red-hot iron has been run through the drainage holes to char the edges, paint once inside and three times outside when perfectly dry, with a preparation of Stockholm tar thinned to the consistency of thin paint with petroleum or paraffin oil, allowing each coat to dry before following with the other. If desired a coat of lead and oil colour may be given to harmonise with the woodwork of the structure. Drain the boxes thoroughly, and place in so much soil that the top of the ball of the plants will be a quarter the depth of the box below the upper edge, making the compost below and around the roots quite firm, then in the boxes, as well as in pots, space will be left for top-dressing the plants after the first trusses of fruit are set and swelling.

—G. ABBEY.

(To be continued.)

ODONTOGLOSSUM CRISPUM SULTAN.

THE display of Orchids at the Drill Hall on the 14th inst. was an exceptionally rich one, for not only were many of the seasonable kinds grandly staged, but new hybrids and varieties were numerous and of excellent quality. Such being the case, this section of the show was the centre of more than ordinary attention, and visitors—expert and otherwise—clustered before the tables. One of the most charming of the Odontoglossums was Sultan, of which the woodcut (fig. 57) will convey an admirable idea as to size and form. It is one of the handsomest varieties that we have seen of late, and the first-class certificate recommended by the Orchid Committee to the exhibitor, Mons. Jules Hye, was well deserved. The whole of the central portion of the flower is bright chocolate red, with margins and very occasional bars of white. The large white lip is very brightly spotted. The spike shown carried three flowers.

DENDROBIUM BOXALLI.

THIS pretty plant is doubtless a natural hybrid, its reputed parents being *D. crystallinum* and *D. Devonianum*. It resembles the latter most both in the flowers and habit, and is equally beautiful. The plants now in flower should be kept cool only as long as they remain dormant. As soon as signs of growth appear, they should go at once into a brisk moist heat in a house where they can get ample light. Growth is most free from small pots or baskets, in which the roots are rather crowded. They cannot endure a large amount of compost about them. When the growth is fully made and ripened, a good rest should be given in a cool house.

HYBRID PHALÆNOPSIS.

THE cut of the fine new hybrid *Phalænopsis* on page 195 reminds one how numerous these lovely hybrids are getting. The first to flower in this country was *P. intermedia*, and this with its fine varieties, *P. i. Portei* and *P. i. Brymeriana*, had long been known, and suspected to be a natural hybrid. This Messrs. Veitch proved by raising and flowering it from seed, the result of crossing *P. Aphrodite*, or as it is better known, *P. amabilis*, and *P. rosea*. The flowering of this kind is a little remarkable, for though for so many years growers had tried without success to hybridise these beautiful plants, only four years elapsed between the sowing of the seed (1882) and its flowering (1886).

A good deal like it is *P. Hebe*, one of Messrs. Veitch's more recent successes, it having flowered in their nursery a little over two years ago. Its parents are *P. leuchorrhoda* and *P. rosea*, so the likeness to *P. intermedia* is easily accounted for. *P. John Seden*, again, is a

beautiful hybrid, well worthy to bear the name of the most successful hybridist living. It also originated under his own hand, and is a cross between *P. amabilis* and *P. Luddemanniana*, the purple spots and markings seen on the latter species being reproduced in the hybrid. Many others of Messrs. Veitch's raising might easily be named; in

FIG. 57.—ODONTOGLOSSUM CRISPUM SULTAN.

fact, Mr. Seden has never looked back since his first success, and has added a lovely section to the most beautiful of Orchid genera.

Other growers have also entered the field, and quite recently Messrs. Hugh Low & Co., of Bush Hill, exhibited a hybrid at the Drill Hall. This was raised from *P. Stuartiana* and *P. Schilleriana*, and had the handsome foliage and flowers that one would expect to see from such a cross. Messrs. Sander & Co., of St. Albans, are also responsible for at least one hybrid, while a look through the houses at either of these large establishments will show quite a number of healthy hybrid plants in all stages of development. The number of hybrids there, although already large, will now increase rapidly, especially as some of the leading private growers are taking up this phase of culture.

SHADING ORCHIDS.

IT is surprising what an amount of care is needed in shading Orchids during the trying days of March and April; we need to be always on the look-out where young assistants have this part of the work under their charge, for either the shading is neglected during bright spells, or it is left down when there is no need for it. Though the injury from the latter may not be so immediately apparent, it is done none the less, for the plants, after our dull sunless winter, require every ray of light possible. Especially in the cool house is this necessary, plants from the high lands in New Grenada and other semi-alpine localities pining for light badly at this time of year.

But they are often in flower, and in order to conserve the blossoms the blinds are dropped, while the young shoots cannot stand the effect under glass of bright sunlight. Just at the present time the value of the lath roller blinds is brought strikingly to notice, these being far better than any description of woven material. During the midday or dinner hour it is always best to have one assistant at least on duty. Sunday mornings, again, have much injury to answer for, and it is quite imperative that whoever is on duty shall be out at the same time as on any other day in the week.

CATTLEYA LAWRENCEANA.

A good form of this fine *Cattleya* is very striking and showy just now. It is a free growing plant where well suited, liking a rather higher temperature and more light than the majority of *Cattleyas*. Not but that it will grow freely enough in a shady house, but there is always a risk of it not flowering unless the growth is well ripened by exposure to sun. The roots of *C. Lawrenceana* are not so large as those of the *labiata* section, nor do they require so much room in pots or baskets. Fine specimens may be reared in the 6-inch size, and plants with only one or two leaves will, of course, need much less room.

Wherever possible keep the plants well up in the house, and avoid syringing. Light syringing on hot days may do no harm, but the water is apt to collect in the young growths to their detriment when a large quantity of it is placed about them. The flower spikes

usually contain from four to eight large flowers, the colour of the sepals and petals varying from nearly white to a pretty deep purple rose, the lip having a fine deep warm purple blotch in front. Though discovered many years ago by Sir R. Schomburgk, it was not introduced in quantity until about 1884, when Messrs. Sanders' collectors found it in British Guiana. According to Mr. E. in Thurm it is usually found in many sheltered positions.—H. R. R.

HYBRID DENDROBIUMS.

USEFUL and showy as are the species of this family, there are many of the hybrids which eclipse their parents, both as regards colour and form. Most of them are good growers, and will repay one for any amount of attention that may be given them. The great aim of the cultivator should be to obtain as large and fine growths as possible, and then to get these thoroughly matured by exposing them to the sun, resting in a lower temperature, and withholding water, taking care that the temperature does not fall much below 50°.

The culture of *Dendrobium nobile* is so well known, and has been given so many times in the Journal, that it is not necessary to repeat it. Let it suffice to state that the majority of the hybrids will succeed under the same conditions. It may perhaps be advisable to mention that the compost should be of the best, and thoroughly well prepared by taking out all the dust and fine particles, and then mixing about the same portion of clean live sphagnum moss. The plants may be grown in almost any receptacle. Some growers prefer pot-shaped baskets, others square ones, but I have yet to learn that any of them are better than a good perforated Orchid pan, such as is made by our leading pot makers.

The hybrids from *D. nobile* and *D. aurum* are no doubt well known, and comprise *D. Ainsworthi*, *Leechianum*, or *splendidissimum*, or its variety *grandiflorum*. Undoubtedly *D. Ainsworthi intertextum* is one of the finest hybrid Dendrobiums yet raised, and in this class I think still we must place the finest and the showiest of them all—namely, *D. Apollo*, and its form *grandiflorum splendidissimum illustre*, which with *rubens grandiflorum* is perhaps without a rival amongst the highly coloured varieties. The whole of these are useful, both to the Orchid connoisseur and to those who only grow Orchids for cut flowers and other purposes. We may now take the *D. melanodiscus* family, with which has been associated *D. Findlayanum*, as one parent or the other. The most beautiful of these perhaps are *Cybele nobiliss*, *pallens*, *Rainbow*, and *Juno*.

Then we have the hybrids, with *D. Wardianum* as a parent, which section, as yet, is not very large, owing to the difficulties experienced in getting flowers to set fertilised with *D. Wardianum* pollen, and *vice versa*, but *D. chlorostete*, *D. e. Owenianum*, and *Aspasia* are most beautiful. I cannot close these notes without mentioning the lovely *D. Venus* (fig. 58), which, though with some growers, like one of its parents, *D. Falconeri*, rather shy in flowering, is still worthy of its place, and should be grown. No Dendrobium I know will stand such a rest as this one, and it must have it to insure its flowering satisfactorily. There are other hybrid Dendrobiums which are well worth a place, but those mentioned will suffice to enable all growers to select for themselves those which are most pleasing to their individual taste.—J. BARKER, *Hessle*.

ORCHIDS AT BOWDEN HILL HOUSE.

At Bowden Hill, near Chippenham, the residence of J. Harris, Esq., Orchids have superseded all other stove and greenhouse plants. Long ranges of houses are wholly filled with them, and evidently the pure air and Mr. W. Penton's able treatment suit Orchids remarkably well. Altogether, 1200 *Odontoglossums* are grown, and at the present time not less than 400 of these are furnished with strong flower spikes. Among them are many good forms, while a large number have yet to be proved. The cooler sections are arranged in two span-roofed houses, where the temperature ranges from 45° to 50°, air being admitted when the latter figure is reached, with the result that clean, healthy growth and well-matured bulbs prevail.

Dendrobiums were a great feature late in February and onwards, some 8000 blooms being expanded at one time. Among the best were *D. nobile* in variety, *D. erassinode*, and *D. thyrsiflorum*. All are grown near the glass, and after having formed strong pseudo-bulbs a thorough ripening, almost amounting to a baking process, has the effect of causing them to flower most freely. They are potted in sphagnum and peat, and those given the most moss are in the best condition both as regards root and top growth.

Cattleyas are flowering grandly, and among them *C. Trianae*,

Schröderi, *Gaskelliana*, *Mossiae*, *Mendeli*, *aurea*, *amethystoglossa*, *Leopoldi*, *Harrisi*, *Warneri*, *gigas*, *Bowringiana*, *Sanderiana*, *Alexandra*, *Victoria Regina*, and *Lawrenceana* in variety are well represented. Several hundred plants are grown, Mr. Harris taking the most interest in this class of Orchids and *Odontoglossums*. *Laelias* are in equally good health, many of them promising to flower grandly. There are enough strong plants of *L. purpurata* in variety, *crispa*, *erispa superba*, *Schilleriana*, *Perrini*, *tenebrosa*, *præstans*, *elegans*, *Dominiana*, and *grandis* to fill a good sized house. Another compartment is devoted to the aneeps section, some of the best varieties of which are *alba*, *Stella*, *Mrs. H. J. Harris*, *Sanderiana*, *albida*, and *Schröderiana*.

Cymbidiums are a speciality at Bowden Hill, and there are numbers of *C. eburneum* in a most promising condition for giving a grand display of bloom. *C. Mastersi* and *C. Lowianum* are in an equally satisfactory state. With these are to be seen numerous plants of *Oncidium tigrinum*, many of them with pseudo-bulbs measuring 11 inches in circumference. Equally luxuriant are the plants of *Odontoglossum grande*, *Cypripediums*, *Oncidiums*, *Chysis*, *Epidendrums*, *Platyclinis*, *Masdevallias*, and *Cœlogynes*, which complete this highly creditable collection of Orchids.—W. I.

"THE ORCHID HYBRIDS."

MR. GEORGE HANSEN, Berkeley, California, writes:—Kindly give me a paragraph in the Journal setting forth that I am anxious to secure the kind co-operation of all Orchid hybrid raisers for the third supplement to my monograph, "The Orchid Hybrids." It will be out some time this summer, and as the material is accumulating so rapidly it seems to be obvious that one index should be printed for all the matter published. I intend to retain the type of such print, and publish only as many copies as I have subscribers, furnishing every purchaser of a supplement with a new index. This appears to be the only way to keep the work up to date and handy.

As to the help desired, I wish everyone engaged in crossing Orchids would furnish me a list of what he has accomplished, regardless

FIG. 58.—DENDROBIUM VENUS.

whether such has been done before at other places or not. It is best to have recorded every cross brought to a successful issue, as it should be known from how many sources our stock originates. Let it be stated in such lists which were the parents, marking the seed-bearing plant; also give date of fecundation and time required to flower the seedling.

SALPIGLOSSIS.—These are beautifully coloured and marked flowers, which make a good display in beds, associating well with Asters. The flowers are well adapted for cutting. Sow seeds now in boxes, prick out the seedlings in other boxes, and transplant to a permanent position in May. Mixed large flowering varieties are the best.—E.

RECENT WEATHER IN LONDON.—The weather in London on Saturday, Sunday, and Monday was brilliantly fine as a whole, though on the morning of the first named day there was a brief spell of semi-darkness. The wind on each day has been cold, but the air is dry and bracing. Snow fell at intervals on Monday afternoon, and again very heavily on Tuesday. Thirteen degrees of frost was registered on Sunday night. Frost was again severe on Tuesday night, but Wednesday opened bright and warmer.

WEATHER IN THE NORTH.—A marked and rapid change took place in the weather of the past week. Up to the 16th the days were pleasant if rather dull; Thursday and Friday were exceedingly bright and warm for the season; by Saturday morning the wind had set into the north, and winter resumed sway. On the mornings of Sunday and Monday 6° frost were registered, and keen northerly winds prevailed up to the evening of the 20th.—B. D., *S. Perthshire*.

MADRESFIELD COURT GRAPE.—At East Thorpe, the residence of Mr. Alfred Palmer, Reading, there is in a somewhat narrow vinery the shortest rods on a Madresfield Court Grape I have seen. The border is 4 feet wide and 18 inches deep. It is also raised so as to bring the Vines near the glass. The rods are only 4 feet long, and have less than that length, for cropping; yet in spite of being thus hard shortened, and also very close pruned, they fruit remarkably well. There are six rods, two coming direct from the main stem and four from a side rod layered into the border. The house is 21 feet long, and contains also three similar rods of Black Hamburgh. The Vines have been planted eleven years. They seem to do wonderfully well so restricted, and bear liberal feeding.

MANETTIA BICOLOR.—A charming and not at all uncommon greenhouse climber is this. The foliage resembles that of *Plumbago* *Larpenæ*, and the flowers those of a *Cuphea*, or the old *Mitraria coccinea*, being tubular, pendent, and scarlet with the points bright yellow. This is much liked by Mr. Woolford, the gardener at East Thorpe, where in a large pot it thrives well, and seems to be always in flower. It is easily propagated by cuttings. Here, too, are great bushes of the old yellow *Coronilla*, old and young *Streptocarpus*, a choice collection of *Orchids*, and spring flowering plants in great variety. In a small Fern grotto *Celogynes* planted in numerous pockets in the rockwork thrive wonderfully and bloom profusely. *Begonia falcifolia*, too, as a basket plant makes a very effective display.—WANDERER.

HESSLE GARDENERS' SOCIETY.—At a meeting of the above Society, held on March 14th inst., Mr. G. Wilson, Swanland Manor, presiding, Mr. H. J. Clayton, of Grimston Park Gardens, Tadcaster, read a highly instructive paper on winter flowering stove plants, his remarks on the culture of *Calanthes* and *Poinsettias* being very valuable. The discussion which followed was of a practical nature. There also was held a decorative competition for under gardeners for a vase of spring flowers, and the Judges appointed were Messrs. W. Pieker and F. Mason, who awarded the prizes as follows:—Mr. O'Donoghue and Mr. Flowers, both of Trauby Croft, first and second respectively, and Mr. Skinner, Bishop Burton Hall, third. The exhibits were of average merit. The usual vote of thanks brought an enjoyable meeting to a close.—J. T. B.

THE READING GARDENERS' ASSOCIATION.—This most energetic and intelligent Society, which has since its birth been instrumental in doing much in the interest of gardening in the Reading district, having recently through his removal from Maiden Erleigh to Sherborne Castle lost the valued services of Mr. Turton as Chairman, is now in danger of losing the services of its excellent Secretary, Mr. John Pound. This admirable gardener, who has been for many years as such to the late Mr. Alfred Sutton, and since his lamented death to his widow, who has also recently died, is experiencing that sort of ill fortune which so often occurs to the best of men after long and faithful service, in having to quit his old situation because death has taken away his employers. There are few vocations that bring such sad changes to men as gardening thus suffers from. It will be a joy for the members of the Gardeners' Association if Mr. Pound can find another worthy place in or about Reading.—D.

ROYAL HORTICULTURAL SOCIETY.—The next Fruit and Floral meeting of the Royal Horticultural Society will be held on Tuesday, March 28th, in the Drill Hall, James Street, Westminster, 1 to 5 p.m. A lecture on "Some of the Plants Exhibited" will be given by the Rev. Prof. G. Henslow, M.A., at three o'clock.

GERMAN SCABIOUS.—These are very showy when in bloom, and most useful for cutting. Dense heads of flowers are produced on slender stems. Sow the seed now in pots and transplant to a cold frame or boxes. Sturdy, well rooted plants will then be secured for planting at the end of May. Fertile ground enriched with decayed manure and well dug suits them quite well.—E.

ANNUAL CHRYSANTHEMUMS.—There are some good varieties among these suitable for growing in beds or borders, to produce flowers for cutting. In a mixed selection of varieties doubles will be included, *Dunnetti* being one of the best. *Atro-coccineum* and *Burridgeanum* are good singles of attractive colours. Sow and treat as hardy annuals, well thinning-out the plants.—D.

DIVIDING AND REPLANTING RHUBARB.—Large old roots of Rhubarb which have not been disturbed for years might with advantage be lifted, divided, and replanted. Secure several good crowns to each division, or divide a large clump into four. The spot selected for planting them must be well dug and heavily dressed with rich farmyard manure. Give a space of 3 feet between each division. Also mulch the surface with manure.—S.

BIRMINGHAM GARDENERS' ASSOCIATION.—Mr. James Dean (manager to Messrs. Pope & Son, seed department) entertained the members at the last meeting with an interesting lecture on "Nature's Seed Sowing," and particularly alluded to various seeds and seed vessels furnished with appendages, remarkable for the distribution towards suitable quarters. The Maple, Elm, and Sycamore were cited as interesting examples of tree seeds furnished with fan-like adjuncts for their dispersion by the wind; and of the sensitive seed vessels, such as the Gorse, Caper Spurge, Balsam, were familiar examples. Those furnished with burrs, spines, and hooked appendages were no doubt intended as provisions for the dispersion of seeds by the agency of the woolly or hairy skins of animals; the four principal agents being animals, birds, wind, and water. Mr. Dean exhibited several kinds of seeds and seed vessels in illustration of his subject, an interesting one being a plant of the Rose of Jericho (*Anastatica hierochuntica*). In the discussion following, and in which Messrs. W. B. Latham (the Chairman), C. R. Bick, Walter Jones, C. H. Herbert, W. Spinks, and W. Gardiner took the chief part, reference was particularly made to vitality of seeds preserved under certain abnormal conditions. Instances were also adduced of the reproduction of seeds after being buried deeply in the soil for many years. The "Orchid Review," in two vols; also the "Iconography of Orchids," in six vols., splendidly illustrated and bound, have been added to the valuable library of the Birmingham Gardeners' Mutual Improvement Association.

DEATH OF MR. WILLIAM MURRAY, PARKHALL GARDENS.—We regret to record the death of Mr. William Murray, which took place on Saturday, 11th March. On the Sunday previous Mr. Murray (according to his wont) was addressing an Evangelistic meeting when he was taken suddenly ill. He was driven home, and gradually sunk into an unconscious state and expired as indicated. Medical skill could render no assistance. The deceased was sixty years of age, and for thirty-three years acted as gardener to Mr. Livingstone Learmonth. Few men in Scotland have attained such success as a Grape and Tomato grower as has Mr. Murray during the past twenty years. His exhibits, of Grapes especially, have held leading positions at Edinburgh and Glasgow Shows for many years. His fame as a cultivator at Parkhall was widely known, where many admiring visitors went frequently to see the crops or remarkably handsome bunches of Grapes. Last year was equal to any previous season in crop and quality of the fruit. The Vines, too, by firm wood and large glossy foliage, testified to the skill of a master hand. Mr. Murray's talents and zeal for the good of his fellows were widely recognised. Among local institutions, he was a member of School Board at Muravon Side, where his remains were interred on Wednesday, 15th March, and much good has been accomplished by his able assistance and force of character. He leaves a widow and one son. The latter now represents the firm of Wm. Murray & Son, which was formed two years ago by renting a large portion of the extensive ranges of glass at Parkhall and a number of acres of land for market purposes. Mr. Murray's portrait was given in the *Journal of Horticulture* for December 22nd, 1898 page 473.—W. TEMPLE, *Carron*.

METEOROLOGICAL OBSERVATIONS AT CHISWICK.

There has been no rain since the 8th inst. The week ending March 18th has been remarkable for five nights and four days of smoky fog, which has left its mark on vegetation.

— THE NATIONAL AURICULA AND PRIMULA SOCIETY.—On page 213 it was stated that the exhibition of this Society would be held on April 19th. This was incorrect, as the date is April 18th, in order that the exhibition may be in connection with the meeting of the Committees of the Royal Horticultural Society in the Drill Hall.

— CHISWICK GARDENERS' SOCIETY.—At the meeting of the Chiswick Gardeners' Mutual Improvement Association on Thursday, March 16th, a paper was read by Mr. R. Lewis Castle, Manager of the Woburn Experimental Fruit Farm, on hardy fruit culture, problems, profits, and prospects. The problems were classed under the heads of tree formation and fruit production, special reference being made to stocks, budding and grafting, pruning, planting, manures, and cultivation as affecting growth or fertility, while as regards the latter particular attention was called to the influence of foreign pollen, and the advantages of interpollination in counteracting sterility. The extreme and average gross returns per acre from fruit culture were noted, and the average expenses, together with the essentials to success. In regard to the prospects it was contended that if the United Kingdom is favoured with peaceful times there is a great future before the cultivator of hardy fruits, because the value of these products as an important part of a healthful diet is rapidly becoming more generally recognised. The discussion was opened by Mr. S. T. Wright, Superintendent of the Chiswick Gardens, who detailed many experiences in support of the principal points. He was followed by Mr. E. Camp, Mr. A. Bridges, Mr. J. Fraser, and several other members, in an animated, interesting, and prolonged discussion, at the conclusion of which Mr. Castle briefly replied on the various points, and the proceedings closed with a unanimous vote of thanks.

— TOWN TREES.—Is the "Irish Farmers' Gazette" quite correct in assuming that Planes make the best town trees because they shed their bark regularly? There are many trees that do well in towns that do not shed their bark, or at least do not do so in the conspicuous way that Planes do; yet may we not conclude that there is with all trees a form of bark-shedding analogous to that of the skin-shedding which goes on in animal life, and is just as efficacious in removing soot or other dirt substances as is seen in the bark-shedding of the Plane? I had thought the primary cause of the value of the Plane as a town tree laid in the thick, hard, leathery character of its leafage. We see the same thing in the Fig, one of the best of town trees, and even room plants are all the more capable of resisting the effects of sooty foul air and fogs the thicker or stouter the leafage. If we take the Lime—a most unsatisfactory town tree—after the middle of summer we find leafage that is thin, and because apparently emitting or becoming coated with a saccharine substance, which attracts aphids, is soon coated with this substance and insect excrement. No such phenomena are seen in connection with the Plane, for its leafage remains clean until the last, and rarely becomes coated with soot or other offensive matter. If I am wrong in these conclusions I shall be pleased to be put right, but at present I fail to see that the bark-shedding theory as put forward by the "Farmers' Gazette" is the correct one. Is it proved that the corky coating we call bark on trees really has stomata or breathing pores to become checked with soot?—OBSERVER.

— HERBACEOUS CALCEOLARIAS AT READING.—The author of Johnny Gilpin in concluding his verse expressed a warm hope that when next his hero rode abroad that he might be there to see. I felt very much as the writer did when he penned this wish, when I saw the other day the remarkably fine collection of plants of herbaceous Calceolarias Mr. J. Martin has grown for Messrs. Sutton & Sons at their Portland Road Nurseries. Whenever these go forth to exhibition may I be there to see them. Certainly the plants are now in luxuriant condition, some of them promising to make a diameter when in bloom of 3 feet, they would present a brilliantly beautiful spectacle when in complete bloom. These will be furnished at the end of May next without doubt, ample evidence that neither in culture nor in form is there anything lacking in herbaceous Calceolarias. The Reading strain is selected with the same care and judgment that is given to other florists' flowers, such as Cyclamens, Cinerarias, Primulas, and others.—D.

— CHESTER PANTON SOCIETY.—At the fortnightly meeting, held on March 18th, Mr. John Taylor, Hoole Hall, and the Hon. Secretary of the Society delivered short addresses on the Potato (in the absence of Mr. John Jackson, who was prevented on account of illness from delivering his paper on Vine Culture). The more practical points dealt with by these two gentlemen were the cutting and sprouting of tubers before planting, the best manures to use, the classes of soils best suited for successful culture, and the best means of preventing the spread of fungoid diseases, so often fatal to Potato crops. The best varieties to use for successional crops were also commented upon, and a collection of some thirty-six varieties staged by members contained excellent samples of Up-to-Date, The Dickson, Sutton's Reliance, Mr. Bresee, Cheshire Prince, Snowdrop, and Clarke's Main Crop, which was generally admitted to be the best flavoured variety yet introduced, although rather behind other varieties in the matter of cropping properties. On the proposition of the President (Mr. John Wynne) a vote of thanks was accorded to Mr. Taylor and Mr. Milb, and Mr. N. F. Barnes, Eaton Gardens, in seconding this, recommended Early Ringleader as being the best and most profitable variety for forcing and for early borders.

— PHYSIANTHUS ALBENS.—In reference to this plant, figured in the *Journal of Horticulture* for February 23rd, I may say that I consider its bad qualities far exceed its good ones, from a bee-keeper's point of view, for anyone who has a plant of it, and will look carefully into it, will find a bee stuck fast in nine out of every ten flowers. The formation of the bloom admits the bee in search of honey, and when its head is inserted into the base it closes tightly round, and prevents its withdrawal. Probably that has something to do with its not fruiting freely in some places, but such is not the case here, as the plant carries large numbers of fruit annually. To anyone having a suitable aspect, and who thought of planting one of them, I would recommend a *Stauntonia latifolia*, or a *Rhynchospermum jasmoides*, as their flowers are more attractive in all ways. The *Stauntonia* also has curious-looking fruit throughout the winter, while the *Rhynchospermum* begins to bloom in June, and continues until late in the summer; its flowers are always acceptable. They will both stand a considerable amount of frost, but in very hard weather they should be covered with a few light Spruce branches. On a south wall 20° will not harm—at least, such is the case here, and the plants now look well.—WM. CAMM, *Battle Abbey*.

— FLOWERS FOR THE WORKERS.—For the past four years Mr. John Crosfield, a prominent gentleman in Warrington public life, has made arrangements for the distribution of Hyacinth bulbs to any of the householders of the working class who should apply for them; and to the most successful cultivators of which he offered money prizes. During October last 1500 bulbs were given away, each applicant receiving three—one each of red, white, and blue varieties. Saturday, March 11th, was fixed for the exhibition, when the Hyacinths were staged in the lecture room of the Warrington Museum. There were four classes provided—namely, two bulbs in pots, two in glasses, one in pot, and one in glass: by this arrangement each recipient had two chances to obtain an award. The prizes in each of the two former classes were seven in number, and ranged in value from 12s. to 1s. In each of the other classes there were six prizes awarded, these ranging from 6s. to 1s. in value. Great interest was taken in the proceedings, as was evidenced by the large numbers of both amateur and professional gardeners who visited the show, admission to which was free. The exhibits also were a marked improvement on previous years, as no doubt the townsfolk have become better acquainted with the details essential to successful Hyacinth culture. There is no doubt that the results are pleasing both to the grower and to the donor who in various ways takes an active interest in promoting and fostering the love of horticulture among the masses, and his example might advantageously be followed by many people.—P. W.

— GARDENING APPOINTMENTS.—Mr. G. Humpbry, for the past five years head gardener at East Hill House, Ashford, Kent, has been appointed in a similar capacity to T. G. Peckbam, Esq., Hall Place, Harbledown, Canterbury. Mr. John Macdonald, for the past four years gardener to Lieutenant-Colonel Courtenay-Bruce, Brook House, Fleet, Hants, has been appointed head gardener to Evelyn Heseltine, Esq., The Goldings, Great Warley, Essex. Mr. J. Garthwaite, for the past two years foreman with Mr. Smith at Eden Hall Gardens, Langwathby, Cumberland, has been appointed gardener to Captain Harcourt Wood, Caerberris Hall, Builth, Breconshire.

PERENNIAL BORDER FLOWERS.

ALLIUMS.

BUT for their odour the Alliums would be grown in far more flower gardens than at present. Onions are useful in their place, but people object to having their somewhat obtrusive odour among the border flowers. Yet this fault is not so pronounced in some of the Allium species that it cannot be overlooked, and others are so effective that they can ill be spared. The Alliums are bulbous plants belonging to that natural order the Liliaceæ, which has given us some of our most beautiful garden flowers. Nearly all are of easy culture in any good soil. Of the large number of perennial hardy species, we can at present only give a selection with a brief description of each.

A. acuminatum, a N.W. American species, is a little tender in cold districts. It has deep rose flowers, and grows from 6 to 12 inches high. *A. azureum*, which comes from Siberia, is a fine species with dark blue flowers in a globular head on stems from 12 to 24 inches high. It is not so easily kept as some. *A. cœruleum*, also with blue flowers in dense heads, is a native of Russia, but is not quite so easily grown as the foregoing. It grows 8 or 10 inches high. *A. Karataviense*, which has white flowers in dense heads, is principally grown for its broad, glaucous leaves. It comes from Turkestan, and grows about 8 inches high. *A. Macnabianum* has deep magenta flowers in good sized umbels on stems about 1 foot high. It comes from N. America, and is a fine species.

The old Moly—*A. Moly*—is a fine plant when grown in a mass, and but for its cheapness and its strong Onion odour would be grown in the most select gardens. It came from the South of Europe about 300 years ago. The flowers, which come in May and June, are bright yellow, and the plant is a foot or more in height. *A. neapolitanum* is one of the best of the white-flowered species. It is scarcely so hardy as some, but is valued because of its white flowers and the less pronounced smell it emits. *A. paradoxum* is a pretty little species with drooping white flowers. It comes from Siberia, and grows about a foot high. *A. pedemontanum*, which comes from Piedmont, is pretty, having clusters of large bell-shaped flowers. It needs a warm place in the border.

A. roseum grows quickly and soon forms a clump from which emerge its stems bearing umbels of lilac-rose blooms. It grows from 1 to 1½ foot high. *A. sphaerocephalum* is a species with closely packed flowers in a ball. The blooms are purple, and as this plant grows from 1½ to 2½ feet high, it has its value among other border flowers. *A. triquetrum* is another pretty species from South Europe with drooping flowers of pure white, and triangular stems and leaves. Some of the Alliums produce little bulbils which drop to the ground and form young plants, but almost all increase rapidly at the root by the formation of new bulbs. Seeds are also produced in this country by the majority of the hardy species.

ALSTRÖMERIAS.

Baron Alströmer, the friend of Linnæus, has been kept in remembrance by his name being attached to a genus of plants noted for their beauty and value in the garden or as cut blooms. Of the large number of species only a few are amenable to cultivation in British gardens. Even these cannot all be depended upon to survive our winters in every garden. One of the hardiest, and at the same time most valuable, is *A. aurantiaca*, a handsome plant 3 to 4 feet high, from Chili. The flowers are orange, and streaked in the upper petals with red. A pretty variety of this, named *A. a. aurea* or *lutea*, is lighter in colour and very bright in the garden or as a cut flower.

Perhaps the finest all-round species, because of its variety of colouring, is *A. chilensis*, which is only a trifle less hardy than the preceding. It is not quite so tall, and has flowers which range from red and deep orange to a pleasing rosy white. *A. peregrina*, which grows about a foot high, is a lovely species, with white or pale yellow flowers striped with rose, and each segment marked with a yellow spot. It is unfortunate that this species is rather tender, while its white variety *A. p. alba*, known as the "Lily of the Incas," is even more delicate. Its beauty entitles it to the shelter of a greenhouse.

A hardy species, not so pretty, perhaps, but desirable as well, is *A. psittacina*, which has flowers of crimson, green, and purple. It comes from Mexico, and has been grown to as much as 6 feet high; it is often seen about 4 feet. There are also a lovely variety or species named *Diazi*, and one named *A. revoluta*, both of which can be recommended for those who have warm and sheltered gardens. Alströmerias ought to be deeply planted in a border of light but rich and well manured soil. They dislike excessive drought, and should be watered freely in dry weather if the drainage is good. The less they are disturbed the better. In cold soils and districts they ought to have a slight covering in winter. They may be raised from seeds, or by division of the clumps of roots in autumn or spring.

In some gardens Alströmerias succumb in a puzzling way, even after having been established for years. The writer finds old lime rubbish beneficial, although not mentioned in standard gardening books.—S. ARNOTT.

(To be continued.)

WINTER GREENS.

THE term "Winter Greens" is one that is used to include comprehensively the varieties of the Brassica family, cultivated to furnish a supply of green and succulent vegetables, chiefly from autumn until spring. When referring, either in speaking or writing, to hardy winter green vegetables, it is more convenient to speak of them collectively by the above term than to name each separately, unless for special reasons attention is directed to one variety. In these notes brief reference will be made separately to each vegetable included in the term Winter Greens.

BRUSSELS SPROUTS.

Seeds of one of the leading varieties of this esteemed and delicious vegetable should be sown at once on a piece of good ground in a warm position. Good varieties are Matchless, Aigburth, Wroxton, and Scrymger's Giant. The best method of sowing is to scatter the seeds broadcast and thinly on a well-prepared bed, and cover with a thin layer of soil, burying the seeds a quarter of an inch. Just as germination commences, if not before, protection must be given against the attack of birds, but after the seedlings have advanced to the rough leaf they will be safe. If crowded thin them well, and when three or four leaves have formed great benefit will be derived by the plants if they are still further thinned, and the best transplanted a few inches asunder to strengthen previous to the final planting, which should be to firm rich ground early in June. Plant in rows 2½ feet apart, disposing the plants 18 inches asunder.

CABBAGE.

For the autumn supply seeds should be sown now. Sowing the seeds broadcast is the best plan, and if it is scattered thinly there will be no necessity to transplant them, but lift and plant finally on well manured ground. The varieties mostly in favour for spring sowing are Sutton's Imperial, Wheeler's Imperial, Heartwell Marrow, and London Market.

CAULIFLOWERS.

A supply of autumn Cauliflowers is indispensable, and they may be had in abundance from seeds sown at the present time. Sow thinly on the surface of rich soil, and transplant to permanent positions when they are large enough to lift with balls of earth attached to abundance of fibrous roots. Plenty of manure should be dug into the ground for Cauliflowers, as large plants are needed for producing good heads. Veitch's Autumn Giant is the best and largest variety, and on good ground it may be planted in rows 2½ feet apart, the plants 16 to 18 inches distance in the rows. Walcheren will come in early, while still earlier varieties will precede it.

BROCCOLI.

Winter and spring Broccoli rank as very important crops, and good breadths of the best successional varieties ought most certainly to be grown. Sow the seeds in small square beds as evenly as possible, so as not to unduly crowd the plants during the early stages of growth. They are frequently planted direct from the seed bed, hence the importance of sowing thinly: but a better system is that of pricking out the small plants to strengthen and form good tufts of feeding roots. Good but firm ground is necessary for Broccoli. It is frequently planted where it is necessary to form holes with a crowbar before the plants can be inserted. There is a special advantage in this for the late varieties, as it prevents the plants making a luxuriant growth, which suffers from the effects of a severe winter.

The first varieties to form close compact heads of the purest white colour and excellent quality are Michaelmas White and Veitch's Self-protecting. These are followed by Snow's Winter White, White and Early Purple Sprouting, Leamington, Cattell's Eclipse, and Late Queen. Plant in rows not less than 2 feet apart.

SAVOY CABBAGE.

This excellent winter vegetable is a most useful crop. Good firm compact hearts are formed, which in the winter are highly appreciated. April is early enough to sow seed, which, like the rest of the Brassica family, requires to be sown thinly. It is an advantage to prick out the seedlings to strengthen. Plant out on rich, deeply dug soil, and apportion the distance between the rows and plants according to the variety. The small sorts only require to be 12 inches apart, while the largest may be 24 inches distance between the rows. The Drumhead Savoy is the largest variety, and Gilbert's Universal the smallest.

BORECOLE OR KALE.

The Kales are splendid winter vegetables, and when well grown are quite ornamental in the garden. Extra Curled Scotch, Green and Purple Arctic Curled, Cottagers Dwarf Curled, and Tall Curled are all excellent, and will provide a succession. Variegated Kale is suitable for garnishing, as there are several distinct colours in one leaf, making it highly ornamental. Seed of any variety may be sown now broadcast or in drills, afterwards transplanting. The final planting should be in rich ground in rows 2 feet apart before the plants grow too large and tall.

In dry weather waterings with liquid manure will benefit all the members of the Brassica family. Keep the ground free from weeds and the surface stirred. Drawing earth to the stems helps to steady the plants.—E. D. S.

PRUNING AND MANURING ROSES.

THE season of planting is practically over, and pruning now demands attention. Recently planted bushes may be pruned at once. They will not be very rapid in commencing growth, and it is best when they do begin that the wood formed should be permanent. I usually shorten the branches to within four or five eyes from the bottom of each. Plants put in last year or in former seasons should be pruned according to their habit. Shy-growing varieties must never be hard pruned, as there is a possibility of crippling them; but robust growers are benefited by a rather severe pruning. Early pruning is a great mistake, as it induces the lower buds to start into growth prematurely, and they frequently suffer for it in being overtaken by frost. Plants which have formed a number of small growths and a few very strong long ones should have the small ones closely cut in, and the strong shoots relied on for a supply of bloom. About 6 inches of growth at most is sufficient. What I have noted might be described as the short-spur system of pruning, but it is not the only mode of dealing successfully with Roses.

PRUNING DWARF ROSES.

When dwarf bushes form growths in the autumn from 5 to 8 feet in length it seems a pity to cut them all off at pruning time in the spring, and where there are many plants grown I would strongly advise that a number of these growths be left uncut and be pegged down. They will not, if very strong, bend to touch the ground, as some may think of trying to root them; but this is not the object, the principle being to bend the shoots and peg them about 1 foot or so from the ground, allowing them to remain full length, and every bud along the stem will soon send up a shoot, and these pegged-down stems will bloom very profusely. For profuse blooming no plan will equal this, and it is rather surprising that pegging is not oftener practised. Anyone wishing to possess a mass of Roses, growing and blossoming in semi-wild profusion, could not do better than peg down the shoots over some beds.

To secure very early Rose blooms there is no better plan than not to prune. In many cases now the shoots on unpruned branches of last year will be a few inches in length, especially near the top; but if these shoots were cut back in pruning all the early growths would be gone, and it would be some time before the lower buds would be so far advanced in growth. For this reason I always allow a few of the earliest bushes to remain unpruned, and they supply me with blooms some weeks in advance of the pruned ones; but as a matter of course the very early ones are not so fine as the late ones, and would never do for exhibition. The pegged-down shoots generally bloom earlier than those cut back, and for that reason this mode of culture is not recommended where exhibition blooms are required.

THE USE OF MANURE.

Plants growing in well-prepared quarters do not require the roots disturbed annually by digging in large quantities of manure amongst them, but judiciously applied top-dressings are of the utmost advantage. Bone manure is applied by taking a little of the surface soil from around the stem, and shaking a handful or two over the roots, and then return the soil. The finest Rose growths and blooms I ever produced were secured in this way. Many persons think their Roses will degenerate if the whole of the surface near them is not deeply forked or dug, and much natural manure added every spring, but nothing is gained by disturbing the roots very much. Roses properly planted by the beginning of March, rightly pruned and top-dressed are sure to give their owners satisfaction from the beginning to the end of the flowering season; and after cultivation will be conducted with little or no expense.

TREATMENT OF TEA ROSES.

These remarks apply to an extensive collection of Hybrid Perpetuals grown exclusively to supply a large number of blooms, but the treatment of Tea Roses against walls, and grown in various ways both in the open and under glass, does not differ much from the above as regards soil and top-dressings. Pruning is done at about the same time, but not so extensively, as my Tea Roses are never much pruned, thinning out the small useless shoots to give more space to the strong ones being the main object in cutting. Very strong shoots formed last year and thoroughly ripened in the autumn will produce much finer blooms than small or intermediate growths, although these generally produce the greatest number of buds. The first blooms of the season on Tea Roses are not as a rule so fine as those which follow, and these will have the full benefit of any top-dressings given to the plants now.—ROSARIAN.

SINGLE ROSES.

THE usual monthly dinner and *conversazione* of the Horticultural Club took place on Tuesday, 14th inst., at the Hotel Windsor. The chair was occupied by Mr. R. Gifton Salmond. The subject for discussion was the "Planting and Pruning of Single Roses," and was opened by Mr. Geo. Paul, V.M.H., who said that a different system must be adopted in their planting from that which was pursued in the case of Hybrid Perpetuals, Teas, and Hybrid Teas. There were three ways in which he said they might be advantageously used—trained horizontally, so as to form a fence or hedge, and for this purpose he advocated hurdles (on which the Roses might be trained), supported by five-barred iron fences; as single specimens on lawns, supported by a Larch pole; or as single plants in shrubberies, amongst other flowering shrubs.

With regard to planting, it must be remembered that as they are to remain permanently they should have more space given to them than the ordinary dwarf H.P. or Teas, and liberal provision should be made for their future welfare. A hole about 3 feet in diameter must be made, and filled with good Rose compost. With regard to pruning, it was necessary to bear in mind that they should be treated very differently from the Hybrid Perpetuals and Teas, only requiring the three-year-old wood to be cut away, the two-year-old wood to be laid in, and one-year-old shoots very slightly shortened.

An interesting discussion followed the paper, in which all present joined, and a cordial vote of thanks was awarded to Mr. Paul for his most interesting paper.

NEW SEEDLING PEDIGREE ROSES.

IN looking over the thousands of new seedling pedigree Roses at Messrs. Alex. Dickson & Sons, Royal Nurseries, Newtownards, Co. Down, I was more than pleased at the great care and attention displayed by this firm in so important a work, with a view to giving to the world other new varieties equally good or even better than those that have taken such high rank in the past few years. It is somewhat strange that while so many lovely light varieties have emanated from this source, the dark forms have been almost nil; but I have little hesitation in saying that ere long we shall see some important step made in the latter class if one must judge by the appearance of several finely developed flowers which were noted.

I could not help thinking that here at all events, for many years to come, we can look with safety for varieties of the very highest quality to make their appearance. The firm's new set, which will be distributed during the coming May, comprises varieties of the highest merit only. Many varieties were carefully criticised, some of which I will refer to in a later issue, but the following were so charming at the time of my visit as to merit their inclusion into any garden where cut flowers and decorative work form a leading item.

Beryl.—A lovely Tea of robust growth and free branching habit, which flowers in great abundance throughout the entire season. The half-open buds, long, and of perfect shape, are highly perfumed, the colour being the richest of golden yellow—in fact, shades deeper than the popular W. A. Richardson, on which it is a great advance.

Meta.—This is at once a superb and novel variety of excellent habit and growth. Here again the half-expanded buds are most beautiful; but although several shades of colour were noted on the plants, the predominating one seemed to be of a crushed Strawberry, with saffron suffusion. Fragrance is another special feature in this charming Tea variety. The above are handsome for buttonhole work.

Daisy.—A very distinct Hybrid Tea of moderate growth is this. The blooms are large, full, and perfectly formed; of a rosy pink colour suffused with silvery pink, and very fragrant. It ought to be very serviceable for exhibition purposes.

Killarney.—Here we have another charming variety of robust growth, and a veritable gem for garden work and cut flowers, the blooms being produced in handsome bunches. The trusses are large, the buds being long and pointed; colour flesh shaded white with pink suffusion. It is a distinct Rose of great merit, and must attract considerable attention.

Ards Rover.—In this fine variety we have a distinct and valuable addition to our climbing and pillar Roses. The foliage is large and handsome; flowers produced in bunches, of a Général Jacqueminot colour, with sweet-scented flowers as perfectly formed. It is a true H.P. climber, and a very welcome addition in the matter of colour.—A VISITOR.

MR. ROBERT SYDENHAM'S NEW PREMISES. — Mr. Sydenham has found it necessary to erect new premises to meet the requirements of his expanding trade. The new structure is built of best Staffordshire bricks with freestone dressings. It is a two-storied building exclusive of the basement and underground stores. The various store, packing rooms and offices are fitted with every modern appliance, including the electric light and a commodious fireproof room containing a large array of business books. It was an interesting sight to watch the staff of employees sorting, packing, and making up seed orders in the various departments with precision and care, a large item being the collection of Sweet Peas, which form a speciality in the establishment.—VISITOR.

CAMELLIAS.

IN reference to Mr. W. Paul's interesting paper on these plants, on page 197, may I be allowed to mention that Camellias are much hardier than most people imagine; and with half the care expended on their culture in pots, they would do well outside in the majority of gardens south of the Trent? There are many plants growing outside here in rude health, the majority of which have been in their present positions from twelve to twenty years. In most seasons they flower well, and when a frost does cut the expanded flowers (as sometimes happens in April and May) they soon recover their beauty, because there are plenty of unexpanded buds which afterwards open. Even in the severe winter of 1895, when we had the thermometer on the grass 8° below zero, the Camellia plants were not injured. There are several varieties, including *corallina*, *elegans*, *alba plena*, and *imbricata*. *C. corallina* opened its first flowers on Wednesday, March 15th, and is generally the earliest.

I find they succeed best in a moist soil, and dry banks, which many might consider favourable on account of the warmth and shelter, are not suitable; while in soils containing much lime provision should be made to prevent absorption from the surrounding soil. In such circumstances beds of peat or vegetable mould will be necessary. The soil here is on the middle lias formation, and many plants which object to lime thrive in our stiff clay without any admixture, but require care—until they get established in the clay—in regard to watering and mulching, because the dry air of summer is liable to penetrate the clay too freely for the first year or two after it has been moved. In addition, we have the benefit of shelter from large timber trees which shield the smaller plants from the full force of cold winds.—W. H. DIVERS, *Belvoir Castle Gardens, Grantham.*

WHEN Messrs William Paul & Son of Waltham Cross, send up to the Drill Hall one of their really superb collections of Camellias, knowing ones toss their heads as with disdain and say, "They are now out of fashion!" I do not care a rap for fashion, for if there is one thing in horticulture that is detestable it is fashion. But fashion apart, if what is thus said be correct, so much the worse for gardening. But whether in or out of fashion, is the Camellia really a less kindly regarded greenhouse shrub now in gardens generally than it has been in the past? If there be any lovers of gardening who would deride the plant, an occasional dose of one of Mr. Paul's beautiful exhibits or a visit to Waltham Cross, should soon work a cure. What intensely green, lustrous leafage; what massive, pure, and withal beautiful flowers; what enduring plants; how easily grown; how readily they bloom in the winter; and what superb objects are fine specimens when in full bloom and in rude health. How is it possible, then, not to treat with contempt the assertion that Camellias are "out of fashion?"—A. D.

ROYAL HORTICULTURAL SOCIETY.

MARCH 14TH.

SCIENTIFIC COMMITTEE.—Present: Dr. M. T. Masters (in the chair); Dr. Müller, Mr. E. F. in Thurm, and Rev. G. Henslow, Hon. Sec.

Dahlia disease.—Some roots were received from Messrs. A. Lister and Son, Rothsay, with the following communication:—"First, we started our roots in the manner we have done for years with the best results—namely, on a hot bench, taking cuttings within three weeks of their insertion, and gradually lessening the heat as time went on. Secondly, the first batch this season was somewhat soft, and all failed; not, however, by damping off, but from the effects of the disease. Thirdly, last season we had magnificent strikes, but near the close of the season, the "spot"—as on the specimen sent—made its appearance, but was very limited. Fourthly, the bottom heat was maintained at about 70°, while the top was about 15° less. Fifthly, Can the Tomato disease have become incorporated with the soil, as Tomatoes had been grown there; and has this any relation to the disease or cause of the trouble? Sixthly, all the roots were placed in comparatively new soil, although some of the old may have been mixed with it. Seventhly, the house is well aired, and the cuttings were firm when taken off. As to remedies, we have applied sulphur with satisfactory results; so far as it killed the fungus at the root and allowed fresh clean growth to be made, but it had no apparent effect on the cuttings. They went off by the score. We have hitherto been most successful in Dahlia cultivation, and have had misfortunes, too, but this disease completely baffles us. The result is the same, both with hard-grown forced exhibition roots, and those grown without forcing."

The following valuable report on the preceding was received from Dr. W. G. Smith, Yorkshire College, Leeds, to whom a vote of thanks was unanimously accorded.

"The Dahlia cuttings when received showed various stages of blackened discolouration, where they had been in contact with the soil, and also on the older leaves, especially where they joined the stem. Where the blackening was worst the tissues were filled with bacteria, and fungus filaments were present. After a few days in a moist chamber the cuttings became black and rotten, the bacteria were more abundant, and the fungus bore colourless spores of two kinds. Your correspondent suggests infection from Tomato disease, previously present in the same house. We find that the two forms of fungus conidia (and only two are present) occurring on this Dahlia material are almost (but not exactly) identical in form with those figured by Mr. Massee ("Gardeners' Chronicle," June 8th, 1895) in connection with the Tomato 'sleepy

disease.' Whether this is a coincidence or a connection, it is as yet too early to say. There is, however, little doubt that this Dahlia disease affects the cuttings in the same way as the above Tomato disease. It has its origin in the soil.

"Remedies.—Your correspondent has tried sulphur in the soil with some good effect. No fungicide, however, will be so beneficial as—

"1, Fresh clean soil.

"2, Ventilation, as far as it can be given.

"3, To water the freshly struck cuttings as little as possible till they form roots.

"4, To use boxes or pans which have been thoroughly disinfected, and to have houses and benches washed down with a limewash.

"In addition to these Mr. Massee recommends for the Tomato disease, to mix as much lime in the soil as the plant will stand. How far these measures can be carried out must lie with the discretion of the grower." Dr. Müller suggested sterilising it, by baking the soil.

Hybrid Narcissi.—Some specimens were received from Rev. C. Wolley Dod with the following remarks:—"I send a spontaneous hybrid which has come in one of my flower beds. It is presumably *N. pseudo-Narcissus* var. *minimus* × *N. cyclamineus*. I also enclose the parents. I consider *N. cyclamineus* one of the best marked species of the genus. It is the only one which has the perianth almost sessile on the fruit. Mr. G. Maw once suggested to me that it might be produced by *N. minimus* × *N. triandrus*, but he overlooked this character—the tube of *N. triandrus* being very long. In the hybrid sent the tube is intermediate between the parents. The trunk of the perianth follows neither parent, being cylindrical, while that of *N. p. minimus* tends to be funnel-shaped, and that of *N. cyclamineus* is always ventricose and contracted towards the mouth. *N. cyclamineus* is a profuse pollen bearer and seed bearer, but the bulb, with me at least, is short lived, and requires constant renewal from seed. I have also observed in another bed a hybrid, *N. cyclamineus* × *N. pseudo-Narcissus*, of some larger variety. The developed tube and glaucous broad leaf belong with certainty to *pseudo-Narcissus*, though the perianth is completely reflexed, as in *cyclamineus*."

RIPLEY CASTLE.

THIS ancient home of the Ingilbys is prettily situated on the edge of the Nidd Valley, close to the model village of Ripley, and three and a half miles north of Harrogate, on the main road from Leeds to Ripon. The undulating park is extensive, and has been judiciously planted with timber many years since, which now contributes largely to the picturesque effect of the country on the west side of the Castle. There is a lake of 35 acres, into which flows a stream at one end, the water afterwards finding its way into the river Nidd. The whole piece has been successfully dealt with to secure a natural appearance, with nicely broken margins and some well clothed islands, and is far prettier than many lakes in similar positions. One is much surprised to hear that it was the work of a Lincolnshire farmer—Mr. Mark Favril—many years ago; he came and dammed up the stream until it flooded the ground to the desired extent, and then took the necessary steps to make it a permanent feature.

The Castle is a substantial but plain building, and is approached from the village by a gateway and tower. The latter dates from the early part of the fifteenth century, and appears to be the oldest portion of the building now remaining; but ancestors of the present Sir Henry Ingilby resided here a century before that date. Among the many old family records and curios preserved in the Castle, mention may here be made of one in the form of a penance inflicted upon Sir William Ingilby for renouncing popery. It consisted of a large amount of walking every night, but was only to continue to the end of the world! A pig of lead stamped with Julius Caesar's inscription and date 87 may also be seen, with a leathern jacket which belonged to Oliver Cromwell, who slept here after the famous battle of Marston Moor, in 1644. The grounds close to the Castle contain no flowers, and thereby are more in character with the building; but the well kept grass lawns and walks are worthy of note, and so is the Ivy on the Castle walls. A fine specimen of *Salisburia adiantifolia* occupies a large space on a southern aspect, and is trained like a horizontal Pear tree, but does not fruit.

A large oblong enclosure, a short distance from the Castle, surrounded by a fine range of hothouses on the north side, and by walls which are hidden by shrubs and creepers on the other sides, contains all the flower beds and herbaceous borders, with enough grass and shrubs to tone down the colours and form a very pleasant picture. Both Sir Henry and Lady Ingilby take great interest in the gardens, and the demand for flowers, fruits, and vegetables is large and continuous. At the end of August a large collection of Eckford's Sweet Peas was in full flower. The seeds are sown in pots early in March, and planted a month later; each potful forms a column of plants 8 to 10 feet high, and continual gathering of the faded blooms induces a succession throughout the season. A border of *Salvia patens* in full flower with a tall variegated Grass dotted in at intervals was very effective; another close by contained finely coloured examples of *Lavatera arborea variegata* mixed with *Ricinus Gibsoni* and other fine-foliage plants.

Annuals are grown extensively and make a great feature in the summer. *Malope grandiflora*, *Lavatera trimestris*, *Schizanthus retusus*, Sweet Sultan in three colours, *Coreopsis Drummondii*, *Gypsophila elegans*, *G. e. rosea*, *Bartonia aurea*, *Cosmos bipinnata*, and Sweet Scabious were noted as the

most effective. Near these a collection of herbaceous plants was growing and flowering well, the border extending to a length of 450 feet. Some of the best in flower at that time were *Dicentra eximia*, *Phygelius capensis*, *Aster acris*, *A. ericoides*, *Hyacinthus candicans*, *Lysimachia clethroides*, *Montbretia Pottsi*, *Verbena venosa*, *Scabiosa caucasica*, *Hemerocallis fulva*, *H. flava*, *Sidalcea candida*, *Bocconia cordata*, *Alströmeria aurantiaca*, *Delphiniums* in variety, and many others. These were backed by the Sweet Peas previously mentioned, and a fine collection of Hollyhocks growing from 8 to 10 feet high. These were the picture of health, and full of flowers; they are raised by sowing seed annually in May.

At the back of this border is the principal range of glass, 450 feet in length; it is divided into eleven compartments, and terminates at each end in a square built stone structure. One of these is fitted as a garden room for visitors to rest in; while the other does duty as a fruit room. Entering from the former, the first house contained a good collection of Zonal *Pelargoniums* in pots. At the back of the stage a hedge of *Plumbago capensis*, 8 feet high, formed a remarkably pretty picture, as it showed to advantage behind the bright coloured *Pelargonium* flowers; on the back

sweetly scented, an old plant worthy of more extensive cultivation; and *Begonia corallina*. The stove contained a fine collection of *Eucharis* in first-rate health, and a plant of *Aristolochia elegans* on the back wall was flowering well, and has not the disagreeable scent of the larger species. A large collection of useful decorative plants was growing here. The central division is devoted to Palms, with the exception of a *Bougainvillea glabra* above, which gives a welcome touch of colour among all the greenery. In the seventh division, among a great variety of flowering plants, *Crinum Moorei* was flowering well; *Petunia Mrs. F. Sander* (which is a very pretty shade of pink), *Swainsonia galegifolia*, *Francoa ramosa*, *Solanum jasminoides*, *Campanula pyramidalis*, and *Streptosolen Jamesoni*, were in splendid condition; a very large plant of *Vesuvius Pelargonium* occupied part of the back wall.

The late vinery contained a fine crop of *Gros Colman*, *Lady Downe's*, and *Alicante*, with *Smilax* and *Adiantums* in abundance underneath, and a very healthy looking plant of the new Conifer from Africa—*Widdringtonia Whytei*—which seemed quite contented under the shade of the Vines, the Grapes were finishing well, good bunches, large berries,

FIG. 59.—IN RIPLEY CASTLE GARDENS.

wall a fine plant of double scarlet *Pelargonium E. V. Raspail* added largely to the effect when seen from the end; a plant of *Heliotrope* known to be over fifty years old was growing on the back wall also. The next division is devoted to Vines, which were carrying a heavy crop of well finished fruit. *Lady Downe's*, *Mrs. Pince*, *Barbarossa*, *White Nice*, *Black Hamburgh*, and *Trentham Black* were all doing well together. The last variety is not often met with, and appears very similar to *Lady Downe's*. Owing to the large demand for plants, Mr. Tunnington is obliged to grow various kinds under the Vines, and succeeds remarkably well, but it is impossible to do full justice to all when grown together, and much labour and anxiety is sure to follow in regard to keeping away insects. The next division was an early vinery, the crop of fruit having reached 220 bunches, which is certainly not a bad one for a house 40 feet long, but these had all been used before my visit.

We next came to the Pine stove, where some famous Pines were grown in years gone by, of which the variety *Ripley Queen* perpetuates the memory; but for various reasons their culture has been discontinued, and the house contained a splendid crop of Tomatoes, the sorts being *Sutton's Ruby*, *Conference*, and *Hackwood Park*; the latter variety is preferred by Mr. Tunnington for winter fruiting. Every corner under glass is made to grow something useful, and in this house were nice plants of a new *Abutilon* with white variegated leaves, very pretty and distinct; *Acalypha Hamiltoniana*, the leaves green and yellow, and curiously jagged at the edges; *Celsia arcturus* flowering well and very pretty; *Rogiera gratissima*,

and perfect colour. Peaches are grown in large numbers in the next two divisions, the latest of which contained some good fruits of *Sea Eagle* and *Prince of Wales* Peaches, and *Pineapple Nectarine*. A Fig tree on the back wall was fruiting well, planted in a border 1 foot wide, and 18 inches deep; a very limited larder, but probably its roots may have found a crack somewhere leading to fresh supplies. The last division is chiefly occupied by *Maréchal Niel* Roses. These were full of strong healthy young wood, trained in long rods near the glass, which is the best way of getting large and highly coloured flowers. The healthiest *Primula floribunda* that I have ever seen, were growing in a very shady corridor close by, and consisted of dozens of plants in rude health, which must form a charming sight when in flower.

Time and space will not allow of more than a few words on the remaining plant houses. Although these are not in accordance with modern ideas structurally, they yet contained grand *Poinsettias*, and many other useful winter flowering plants. The kitchen garden, too, deserves more than a passing notice, part of it having been under cultivation for hundreds of years, but with skilful management and close attention good crops of vegetables are still grown, although this is by no means a favourable locality as regards climatic conditions. In one portion of the vegetable quarters were many fine *Chrysanthemums*, from which it is apparent that Mr. Tunnington inherits some of his father's ability in their culture, as the whole of them were in the best of health, and clothed with foliage to the rims of the pots.—W. H. DIVERS.

THE KINGSTON CHRYSANTHEMUM SOCIETY.

IN spite of some adverse times there seems to be a good deal of life in this old Society yet. Although not the oldest in the kingdom, yet it is one of the earliest formed, and is now in its twenty-third year of existence. At the annual meeting of its members, held on the 17th inst., Mr. W. Drewett presiding, the balance-sheet—though because of the severe illness of the Hon. Secretary, Mr. W. D. Elsam, was not complete—showed that during the past year previous liabilities, to the extent of some £30, had been paid, and it was hoped when all assets were secured that only a very trivial balance against the Treasurer would remain. Had the second day of the last November Show been propitious, rather than very wild and wet, no doubt a balance on the other side would have resulted. The meeting regretted to learn of the resignation of the President, Mr. G. C. Sherrard, but hoped that the office might be filled by a gentleman of position in the county.

It was agreed to hold the Show for the present year on November 8th and 9th, and thus not conflict with the first day of the National Society's Show at the Westminster Aquarium—viz., November 17th. It was also agreed to dispense with any challenge vase, and to have a premier class for thirty-six Japanese flowers in place thereof, valuable cash prizes only being offered. The old members of the Committee, with few exceptions, were re-elected, the additions being Messrs. Gibson, Kingston Hill, and Telsell, Sunbiton, gardeners, and Messrs. Hill and Mussell, amateurs. An offer from the Hon. Secretary to organise concerts in connection with the next Show was cordially accepted.

CHRYSANTHEMUMS AND THEIR CULTURE.

MR. G. STILES, gardener to Miss Fripp of the Grove, Teignmouth, and one of the leading growers of Chrysanthemums in the West of England, lectured on the culture and judging of the flower to the members of the Devon and Exeter Gardeners' Association recently. He pointed out that cuttings for exhibition blooms should be rooted in December if possible, and not later than February, and cuttings ought to be selected from those which come up from the soil. Cuttings taken from the wood were prone to throwing flower buds. Those selected for rooting should be short-jointed, medium-sized, and healthy. The compost ought to consist of loam, leaf mould, and sand in equal parts. The best way to root cuttings was to put them in shallow boxes, about 2 inches deep, and place them in a frame with a gentle bottom heat of about 55° to 60°, keeping them as near the glass as possible, and be sprinkled over with warm water, care being taken not to let the soil get too wet. Just a little air should be given every day, and they ought to be slightly shaded from the hot sun on bright days for a short time. In about a fortnight or three weeks most of the cuttings will be rooted, and more air must be given them by taking off the lights gradually every day until on fine days they might be removed. By doing this the plants would be sturdy and strong, one of the main points in Chrysanthemum culture.

After potting they should be placed in a gentle heat in a frame or house. As soon as the roots begin to catch hold of the new soil they should be removed to a cold frame or greenhouse, given plenty of air, but protected from the frost. Care must be taken not to overwater. Plants grow too soft if too much water is used over the foliage, and syringing once a week is quite enough. Their next potting should be in a compost of two parts good loam, one leaf mould, and the other part sand, lime rubble and charcoal, with about half a pound of guano to a wheelbarrowful of this mixture. The plants should be placed in a cold frame till the end of March, when they could be put in the open. About the middle of May the final potting ought to take place, and the compost should consist of good fibrous loam a little over two parts, one part leaf mould, and the remainder lime rubble and good decayed manure, with a sprinkling of charcoal, and about a pound of guano to a wheelbarrowful of the soil. In potting the soil should be made moderately firm, excepting for a few varieties, which require to be potted rather lightly. In their summer quarters the plants should be quite 2 feet apart in the rows, in rows 5 feet asunder.

The first bud, which would show itself about the end of May, must be removed, and the number of shoots should be left that the plants were intended to carry. He seldom practised pinching. He recommended for liquid manure, which he commenced to use about the end of July, fowls' manure and soot. After the 1st of September sulphate of ammonia could be given twice weekly, about 4 ozs. to 5 gallons of water. Dressing of blooms should commence as soon as they are half open, by removing all crooked and deformed florets as

they appeared, so as to let the flower attain to its proper shape as it opened. If any of the flowers showed hard centres, or eyes, in opening, these should be gradually removed, so as to let the inside florets come up full in the centre as the bloom expanded. This applied to the Japanese varieties. The incurved required much more attention. The essayist gave advice as to the treatment of these, and in referring to the judging of the blooms, he called attention to the importance of judges seeing that the trays were of the regulation size. He contended that every exhibitor should be disqualified who did not show his exhibits on the regulation sized tray, and when there was any doubt as to the award, the trays should be placed side by side, and each bloom taken out and compared. Mr. Charley, gardener at Wonford House, occupied the chair—"Devon and Exeter Gazette.")

A TRANSFORMATION.

WHY do we allow our fruit tree branches and stems to remain covered with moss and lichen, swarms of red spider, and scale? is a question I have often asked myself, and could never find a satisfactory reply. As these pests must be detrimental to the welfare of the trees I set about their extirpation. Early in February I procured 6 lbs. of caustic soda, 98 per cent., and 5 lbs. of carbonate of potash, and dissolved the two in 60 gallons of water. When all was thoroughly dissolved I added 4½ lbs. of soft soap. Our fruit tree stems and branches become green in one year if nothing is done to kill the lichens, for which purpose I have generally used soot and lime. On occasions brine has been employed, as it is useful and inexpensive. This season, however, the trees were dressed with the caustic solution, and the stems are now a pleasure to look upon. All the greenness has gone, and there are the dark bright stems. The red spider was destroyed, and the scale on the branches of the Pear trees on the walls are now falling off and leaving small white specks on the bark, showing where they have been sucking the life of the trees. I applied the dressing myself with an Abol syringe, which I found the best for the purpose I have used or seen. The operator can have a fine or coarse spray at will by simply turning a small screw. I spoilt two pairs of leather gloves in applying the solution, which the operation hardened and burned them, and they afterwards cracked. Boots and clothes were also damaged, and it was not pleasant when a light breeze of wind happened to send a little of the spray into the face. The work was tedious, but I have never done anything with which I was better satisfied. It is important that this solution be applied before the buds show signs of expansion.

Two years ago I dressed the trees with the same quantity of caustic soda (I ordered the quality 98 per cent.) and carbonate of potash, but not the soap. When Mr. H. H. Cousin's "Chemistry of the Garden" was notified in the Journal I procured one, and I consider it one of the most valuable little books in the English language, and it must prove to be a boon to every British gardener who would read and digest it thoroughly. It was in reading this primer that I first learned the fact of soft soap being advantageous with the caustic solution. When, as I have said I used the mixture minus the soap the dressing did not pay for the labour, partially perhaps owing to the chemicals being old.

Fruit trees appear to be showing abundance of flower buds this year, but we may have several checks before the next two months have gone.—GEO. PICKER.

ROYAL METEOROLOGICAL SOCIETY. — The monthly meeting of this Society was held on Wednesday evening, the 15th inst., at the Institution of Civil Engineers, Great George Street, Westminster. Mr. F. C. Bayard, LL.M., President, in the chair. Mr. F. J. Brodie read a paper on "The Prolonged Deficiency of Rain in 1897 and 1898." For several years past there has existed over England, and especially over the central and south-eastern parts of the country, a remarkable tendency in favour of dry weather. The dry weather dealt with in this paper consequently came at a most inopportune time, and its effects, which would in any case have been sufficiently evident, were greatly aggravated by the state of things existing so long previously. Mr. Brodie discussed the rainfall records at eighty stations, distributed over the British Isles, for eighteen months—April, 1897, to September, 1898; these were divided into three periods of six months each. During the period April to September, 1897, the rainfall was in excess of the average over practically the whole of Ireland, the greater part of Scotland, and the north-west and south-west of England and Wales, while in the north of Scotland, and the central and the whole of the eastern part of England there was a deficiency of rain, in some parts amounting to between 60 and 70 per cent. During the period October 1897, to March, 1898, with the exception of the north-west of Scotland and England, the rainfall was below the average all over the British Isles, the deficiency over the midland and south-eastern parts of England being from 50 to 60 per cent. below the average. During the period April to September, 1898, two of the six months were excessively dry, and in the southern parts of England at least two others had a deficiency of rainfall. Taking the period as a whole, the rainfall over the eastern, midland, and southern counties amounted to less than 80 per cent. of the average, and in the south-eastern counties to less than 60 per cent., the smallest proportion of all being 51 per cent. in London. From an examination of the Greenwich rainfall records since 1841 it appears evident that for length and severity combined the recent spell of dry weather was the most remarkable experienced there during that period. A paper on the "Climate of Jersey," by the Rev. H. W. York, M.A., was read by the Secretary.

LONDON GARDENS OVER FIFTY YEARS.

No. 5.

AMONGST the events associated with the Diamond Jubilee of our beloved and honoured Queen was the formation of a committee, composed of members of the Commons Preservation Society, the Kyrle Society, and the Metropolitan Public Gardens Association, by which a letter was addressed to all town and district Councils, also to a number of landowners. The object of this was to induce the setting apart in every locality a plot of ground, to be called the "Queen Victoria" park, garden, playground, or field, as it might be, such open space to be dedicated to the free use of young and old.

Already the appeal is bearing fruit, and, in the vicinity of the densely populated districts of London it is particularly important that still further provision be made of public gardens—a portion devoted to the sports of the young in some cases, but chiefly planted with shrubs or trees, and made bright by flower beds. As such gardens, small and large, multiply, there is no doubt they will tend to promote a love for flowers, and encourage gardening pursuits, especially amongst the class which needs to be drawn from low and mischievous pleasures. Some of the smaller plots about London surprise us by their display through the greater part of the year, but of course they cannot afford room for many shrubs, the beds being kept well filled with plants having attractive foliage or showy flowers. So great is the popularity of some gardens now opened in London suburbs, that the gardeners find it impossible to work satisfactorily during the hours when the public are admitted.

London horticulture is already greatly indebted to the exertions and influence of the Metropolitan Public Gardens Association just mentioned, and next century, we may hope, will evidence grander results still should its income enlarge. At present its funds are inadequate to its opportunities; but the money expended represents only a part of the useful work done by this Society, of which the Earl of Meath was the chief originator in 1882. Previous to that, the Kyrle Society and the National Health Society had been actively engaged in the work of acquiring and laying out various open spaces amid a crowded population, mostly neglected churchyards, where interments had been stopped after 1853. Even then there was a danger lest these should be built over, or converted into yards for business purposes, and an Act of Parliament had to be obtained securing them from desecration. It was felt by Lord Meath and others that a society formed for the special purpose of increasing public gardens throughout London had an ample field before it, and when it reached its semi-jubilee the society could show a good record. Above a hundred gardens and recreation grounds had been laid out, or purchased, by the Association, and by its agency many hundreds of trees had been planted. Amongst the larger enterprises on which it has recently been co-operating with other bodies is the preservation intact of Chelsea Physic Garden and of Alexandra Park, also the acquisition of Golders Green and Dollis Hill, besides a fine space upon the bank of the Thames at Wandsworth.

The Metropolitan Public Gardens Association made no great display at its commencement, beginning upon churchyards, small neglected squares, and other spaces which could be secured by a moderate outlay, then put in order cheaply. Enterprises which look little besides such schemes of the London County Council as the purchase and laying out of Ravenscourt Park for £62,000, and Brockwell Park for £122,000, yet many a space of but an acre or two, perhaps less, made free to all, and planted as a garden, is an oasis in the desert of crowded houses and narrow streets to the sick or aged, and often to the weary toiler also. One difficulty with reference to some churchyards has been that, an opposition being made to the removal of certain tombstones, they could only be partially converted into gardens. Then there are churchyards open to the public, several of good size, which have not had their graves interfered with at all, still they furnish places for a stroll amid shrubs, trees, and some scattered plants of a varied nature. An example familiar to West Londoners is the ground in Bayswater Road belonging to St. George's, which is nearly 6 acres in extent. The smaller ground belonging to the Vestry of that parish, in Mount Street, is very tastefully laid out.

In two or three instances the people living around a London garden are so rough that it is impossible to preserve flowers or shrubs from damage, but generally even the irrepressible cockney urchin understands that he must keep his fingers off the plants. I cannot say how it might be if there were fruit to be got at. There, I admit, is an objection to a proposal of mine, that for the sake of variety some fruit trees should be planted in our metropolitan open spaces. One of the ancient City churches, according to tradition, stood in a grove of Apples, and in our time the Charterhouse Burial Ground had several magnificent wall fruit trees. But the only fruit we are likely to discover about most old churchyards is the Elderberry, this tree being often set formerly as a sacred plant possessed of many virtues.

We have referred to five London churchyards, which might be said to have occupied the position of pioneer gardens, when it was being

impressed upon the public mind that even a small open space could be made a pleasant resort, if not given up to cats, sparrows, and all sorts of refuse. Within the central part of London, the churchyards now open are not chiefly frequented by the poor, but give a rest or refreshment to the busy City clerk and the warehouse worker. Very cheerful some of these plots appear in springtime through the judicious planting of bulbs and tubers. A choice nook is the little garden of Benjamin Street, near Farringdon Road, but a quarter acre, once the ground of St. John's, and after it was closed for burials it fell into the hands of a builder, who covered it with workshops. Happily it was rescued, the space cleared in 1881, and since it has been well kept. During fine summer days, crowded is the so-called "postman's park," the old churchyard of St. Botolph's, Aldersgate, enlarged of late by the acquisition of two other grounds abutting. About the same dimensions are the valuable spaces of St. Olave's, Silver Street, and Allhallows's, London Wall, and that of St. Dunstan's in the East, Idol Lane, which has some old trees in a flourishing condition. Obviously, when such grounds have the flower beds partly shaded by trees, it is only certain plants that will thrive, and sowing annuals is apt to be unprofitable. Amongst other novelties, in some of these gardens is a columbarium or pigeon house, as its occupants furnish amusement to children, but I query whether pigeons ever prove good gardeners.

Occupying the position it does in a much frequented part of the City, St. Paul's Churchyard has daily its thousands of visitors; the extent is about 2 acres, but it is not at all garden. Not a bad spot to take a hasty lunch, with the Cathedral close by to retreat into for a cool contrast in summer. The City is not a place of squares, we go westward or northward to find these; yet some there are of old date, which have now been improved and with other odd scraps of land changed into gardens. During the eighteenth century several of these squares were not even enclosed with posts, and laid in a waste condition; two or three are said to have been small nurseries, supplying seeds and plants to the well populated streets adjacent. Out amongst the suburbs, too, it was not unusual for a nursery, which had occupied acres, to shrink finally into the centre of a square, and then disappear. We have an example in Ebury Square, Piccadilly, which, after sundry vicissitudes, is still kept as a public garden. Close to the old Smithfield Market, in Long Lane, we come upon a clear space of but a rood, and a similar plot near Brooke's Market, Holborn, has been rescued from the builder. Both are now laid out as gardens, with fountains, and are a great boon to a poor neighbourhood. Northampton Square, Clerkenwell, an open ground which was a leafy surprise to the by-passer who came up to it from one of the radiating streets, has been public since 1885, over £1000 being spent in laying out this and Wilmington Square near, once a nursery where Auriculas and Polyanthus attracted North Londoners.

Since the spring of 1888 the Tower Gardens, 2 acres in extent, have been made a free resort, the ground being admirably laid out. Previous to that date the name "garden" would have been a misnomer, for the space was in a very neglected condition. The valuable acquisition by the London County Council of Lincoln's Inn Fields with its 7 acres ended a struggle which had been going on for many years to secure this area for the public benefit. Someone has described the amazement shown by the children of the locality on being allowed to enter the precincts, which they had often looked at through the railings. There are some good trees, and the ground still retains the impress of the style of gardening popular in Georgian times, for the legal gentlemen who managed it formerly did not modernise much.

Going north or east of the City we come upon many churchyards, several rather extensive, which some twenty years ago looked doleful indeed, but are now healthful and pleasant gardens. St. Dunstan's, Stepney, has nearly 7 acres, and was opened in 1887 by the Duchess of Leeds. It displays a variety of trees and shrubs, besides flowers. The churchyard of St. John at Hackney is 6 acres; but only part is garden, the rest grass. All Saints', Poplar, is about half that size. It was opened by Lady Reay in 1893, and is well kept. Of similar extent is St. Anne's, Limehouse, also opened twelve years ago by the Countess of Strafford, and which is greatly appreciated. Almost attaining to the dimensions of a little park is the space called Meath Gardens, of 11 acres, and Victoria Park Cemetery, opened by the Duke of York in 1894. Bethnal Green Gardens, of 6 acres, was only secured to the inhabitants after a long and arduous struggle. Its flowers in summer have thousands of visitors.—J. R. S. C.

ERYTHRONIUMS AND CHIONODOXAS IN POTS.—It would be difficult to say which of the two mentioned plants ought to be held in the highest esteem for pot culture. Both are so admirably adapted to this purpose to be used as front-row plants as to necessitate their being grown by anyone possessing a small house, whilst for larger displays they cannot be overlooked. The grandiflorum type of *Erythronium dens-canis* has fine flowers and foliage. Not only are the flowers quaint and pleasing, but the foliage also is handsome. The shade of blue of the *Chionodoxa* is sufficient claim for its inclusion also.—R. P. R.

GROWING CROTONS.

AMONGST ornamental fine-foliated stove plants the Croton stands in the first rank for the rich colour and gracefulness of its leaves. Most varieties differ so much in habit as to make them well adapted to be grown in great numbers together without looking monotonous. Few plants are more beautiful when well grown than a collection of Crotons when the sun is shining upon them. The large dark red foliage of Baron James de Rothschild, the rich golden bronze of Queen Victoria, and the large golden blotched leaves of Morti, blended with the pale yellow and green foliage of variegatus, and the stiffness of these taken off by the graceful drooping foliage of such varieties as interruptus, interruptus aureus, ligarius, Weismann, Cyrus, Cheloni, aureo-punctatus, Princess of Wales, elegantissimus, Warreni, and many others, is a sight to be remembered by all interested in the cultivation of fine-foliated plants.

To perpetuate a variety of any plant it must be propagated by cuttings, buds, or grafts, as those raised from seed rarely come true. As a proof of this I may mention that I have at present six seedling Crotons, from 4 to 5 inches high, raised from one of the narrow-leaved varieties, and not one resembles the parent plant, and no two of them are alike. They differ much in the colour and shape of their leaves, and also in the habit of their growth. Some have narrow leaves of different shades of colour, while others have broad green leaves with no sign of variegation whatever.

PROPAGATION.

Crotons can be propagated at almost any season by inserting strong cuttings of half-ripened wood in small pots in a soil or composition made of equal parts of loam, leaf mould, and silver sand, and plunged in a gentle bottom heat until they are rooted. During this stage the cuttings should be dewed over the foliage with a fine-rose watering pot every day to keep the leaves fresh, and to prevent red spider attacking them. When the cuttings are sufficiently rooted, which will take from three to six weeks, according to the season, they are shifted into pots a size larger, using the following compost: three parts of good fibrous loam, one of peat, one of leaf mould, and about a third of the whole of sharp river sand, which will keep the compost fresh and porous. The plants are then placed in the stove close to the glass, where they will receive as much light and sunshine as possible. As the plants increase in size they are shifted into larger pots, always using the same compost as that just mentioned.

Great care must be exercised in watering the plants. The soil should never be allowed to become too dry or too wet and sodden, or the roots will be injured and decay, and the plants will suffer in consequence. The roots of the Croton are soft and spongy, and are therefore liable to damp off if the soil becomes wet and sour on the one hand, or too dry on the other. Great care and attention should therefore be paid to watering at the proper time, and in sufficient quantity to keep the plants in a healthy growing state.

THE USE OF MANURE.

It has been truly said that one of the secrets of success in the cultivation of any plant is the frequent and judicious application of manure. This is especially so with regard to the Croton. The great amount of foliage which a large and healthy plant has to nourish soon extracts all the fertility from the soil in which it is potted. It is quite different with plants growing in the open air. The soil in which they are growing is always receiving, more or less, natural manures from the rain, for rain and snow never fall to the earth without carrying fertilisers with them. As a matter of course plants grown under glass receive none of these, consequently if they are to be grown successfully manures must be applied artificially, and in greater quantities to large plants that have filled their pots with roots and are growing vigorously, than to those whose growth is at a temporary standstill. The fertilisers I apply to Crotons are liquid cow manure and soot. These are thoroughly mixed together and used when watering.

INSECT ENEMIES.

Crotons are subject to the attacks of several insect pests, but the worst I think is red spider. If once this has possession of any plant its health is ruined in a short time, and the leaves fall one by one, completely disfiguring it if the spider is not checked at once. The yellow varieties I find are more subject to its attacks than any of the others. The best plan is to give the plants a thorough, and individual, syringing as soon as the pest appears and wash it clean off. But prevention is better than cure, and I think if the syringe were used judiciously every day red spider would be kept under.

Thrips are also great enemies to the Croton; if once they get on a plant the leaves are soon disfigured and ruined, no matter how excellent the treatment may have been. A sharp look out should be kept at all times for this pest, for, unlike red spider, its effects on the plant are not seen all at once, and it is only by close investigation that its presence is discovered in its early stage of development. To get rid of thrips I know two methods—the first is by fumigating the house, and the other by syringing the plants with a decoction made from tobacco paper mixed in water.

Scale is another pest which sometimes infests Crotons, but it is easily killed by syringing with a little petroleum mixed in water and kept in perpetual motion while being applied to the plant. Mealy bug can be destroyed in the same way.

POTTING AND TRAINING THE PLANTS.

I have said nothing about draining, potting, and stopping the shoots to make well-furnished bushy plants, or about bent, moisture, and the

ventilation of the house. The pots should be thoroughly cleaned and well drained for all plants that have to be grown for any length of time in them, and in potting the plants are placed a little lower than they were in their previous pots to cover the top of the ball. The soil is pressed firmly down, and when finished sufficient space is left at the top of the pot for watering. The plants are trained with as few stakes as possible to put them in shape, and the strong shoots stopped shortly before they begin to grow in the spring, to make them branch out and furnish the plant with fine leaves from top to bottom. The temperature of the house should be kept at 70°, and ventilation afforded when the heat rises above that degree in sunny weather, and it is allowed to rise to 80° or 90° with air in the summer time. When the plants are growing they require abundance of water. They are syringed twice a day, and the bed and path damped frequently.—P.

ROYAL GARDENERS' ORPHAN FUND.

LIKE Mr. J. B. Stevenson (page 222), I find it very difficult to persuade gardeners to subscribe to this, in my opinion, deserving Charity. It has always been a mystery to me why they will not do so, but I am constantly met by the same remarks as your correspondent. At the present time I have no private gardener on my books, although I have acted as Local Secretary since the Fund started. I have much more difficulty now than I had at first in getting gardeners interested, and have thought it would be a good plan to inaugurate public meetings in some of the towns or districts where gardeners are numerous, and then for our new Secretary (who, by-the-by, I congratulate upon his appointment) to come and explain the objects and working of the Fund.

I quite feel there are times when it is necessary to give the benefit to more than one child, but not when there are several others of the same family earning money. There is no doubt gardeners as a class are not overproud. A gentleman a few days ago told me it was difficult to get good gardeners. I pointed out to him he was paying his mechanics and labourers better than he paid his gardener. Notwithstanding this, however, our Fund ought to win more support than it does.—A. J. BROWN, *Local Secretary, Chertsey and District.*

NOTES ON YOUNG VINES.

To have Grapes ripe at the end of March or the beginning of April the Vines to produce them must be started not later than November, and as they will have to make growth and perfect the crop under adverse external climatic conditions, it is imperative that cut-backs of last year's raising should now receive their final shift, so as to allow time for them to make and mature a good growth early. The pots, 12 inches in diameter, must be clean, efficiently drained, and have a layer of the roughest of the compost on the drainage; avoid bones, as they favour various animal pests. Pot firmly in good fibrous loam, with about a tenth of old mortar rubbish, a pint of steamed bonemeal, a quart of soot, and a gallon of wood ashes to each barrowful of loam. The Vines are best placed on shelves over the hot-water pipes. Keep the house rather close, and if the weather be bright shade for a few days. Train the canes about 4 foot distance from the glass, and give all the light practicable to insure the solidification of the growths.

The planting of young Vines should be done when they are starting into growth, and not more advanced than an inch or two. Where provision has been made for inside and outside borders the Vines should be planted in the former, which will be sufficient for several years, as a width of 4 feet is ample the first year, and about 2 feet width can be added annually. Some growers prefer to do this every second or third year, adding to the border about 4 to 6 feet width. The Vines, if cut-backs of last year, may be shaken out and placed in position either before or after they have grown to the extent of an inch or two, the roots being disentangled and spread out evenly in the border, covering them about 3 inches deep, and watering moderately to settle the soil about them. Vines of the present year's raising will not need to be planted for some time yet. They are preferably raised in squares of turf, and may be planted when the roots are protruding through the sides, the breaking of the rootlets extending beyond favouring a fibrous root formation, or if in pots they should be turned out before they become root-bound. They will require a temperature at planting suitable to Vines in growth—that is, 60° to 65° at night, and 70° to 75° by day, with an advance of 10° to 15° from sun heat. Vines of last year, however, should be allowed to start unaided, syringing them two or three times a day according to the weather, and ventilating freely at 65°, with a little from 50°.

Young Vines planted last year and cut back to the bottom of the rafters or trellis at the winter pruning must be encouraged by gentle fire heat to allow time for their making and perfecting a good growth. The laterals should have their points pinched out at the first leaf to a height of 6 feet up the canes, which will cause the buds in the axils of the principal leaves to form fruit buds and become plump for next season's fruiting; above that height they may be allowed to grow. It is a better plan, however, to stop the cane at about 7 feet 6 inches, train a lateral from it as a continuation, stop this at 3 feet, and so on until the top of the house is reached, stopping all laterals to one joint, and sub-laterals to one leaf as made. This secures the roughly ripened growth and a stout cane from the base upwards. Where the canes have been pruned to three buds of the lot on of the rafters or trellis the growth from the uppermost should

be trained forward as leader, and the laterals or side-growths from the rod be trained one on each side, pinching them at one or two joints beyond the show for fruit, this being the object to test the varieties, and afterwards keep the laterals pinched to one leaf as produced. It is not wise to allow the Vines to carry many bunches the first year, but regulate the bearing according to the vigour of the Vines.—GROWER.

TECOMA JASMINOIDES.

ALTHOUGH by no means a new plant, *Tecoma jasminoides* (fig. 60) is unknown in some gardens. When properly managed it is a beautiful plant for greenhouse decoration, and is usually much admired. The flowers are produced freely, and vary from white with a rosy centre to a uniform pink hue, differing in the brightness of tint, and some of the best marked of these variations have received distinctive names. The plant succeeds in a compost of turfy loam, peat, and sand, or good leaf soil can be substituted for the peat if more convenient. Planted out it grows freely, but it also thrives in a pot, needing thorough drainage in any case.

SOUTH AFRICAN FRUIT.

DURING the last month connoisseurs in fruit have had the opportunity of enjoying what is to most a new luxury. This is the finest fruit of Cape Colony, some of which has been placed upon the London market. There are still great difficulties in the way of its transport, as freezing destroys it, and the maintenance of a cold chamber at a proper temperature gives more trouble than the steamship companies like. But what does arrive in good condition is incomparably good. The large heart-shaped Plum, as full of juice as a Peach, Apricots with a double share of Apricot flavour, Peaches without a suspicion of the bitterness of Californian Peaches, and Williams' Bon Chrétien Pears, are the most prized. There are also three varieties of Grape, small Black Cluster Grapes, and two large varieties, with Muscat flavour, one black and the other white, all grown out of doors, but not inferior to English hothouse Grapes.

The Cape has a great advantage over California for profitable fruit growing. Its seasons are the converse of ours. While we are freezing, the South African sun is ripening the orchards and vineyards of the Old Colony. Nature does so much for the Cape farmers that we wonder that they have not done more for themselves. The perfect climate produces fruit of a flavour unsurpassed in quality, and in quantities as great as Nature almost unassisted will grant. In January, when dessert on English dinner tables is supplied mainly by the dried fruits—the Raisins of California ripened in the previous summer, dried Plums from Bosnia, or dried Figs from Ionia, with only the Orange and hothouse Grapes to give juice and lusciousness—the colonists are picking the last of the Strawberries and Apricots for themselves, and making ready for sale or export exactly the kinds which those who are compelled to eat dried fruit here and in the United States would welcome most eagerly. Early Grapes, exquisitely flavoured Pears, early Peaches, fresh Figs, Plums of a size and flavour surpassing any grown in this country except in the hottest summers, are ripening on the trees of the "Old Colony."

February at the Cape produces the finest of English Peaches and Nectarines, mainly of the late-ripening varieties, which are as a rule the very best in flavour, even of these choice fruits. The difference is that what can only be grown in perfection under glass here, or under exceptionally sunny walls in favourable seasons, is there produced in abundance on standard trees. This fruit can be in London within a month of being gathered, and packed in cold chambers is brought here with the bloom still on the Plums, which look and taste as fresh as if gathered in the garden. This is at a time when the east wind is whistling through the streets, and not a bud as yet appeared on our own Plum and Peach trees. It is in February, also, that the Cape Grapes come to perfection, and have the best and truest flavour. Of these the Colony produces one variety in rude abundance, and does produce a few, and might produce a great quantity, of very high quality.

Wine-making is an ancient industry at the Cape, and the most remarkable thing about the Cape Colonist's wine is that though it has never been properly managed or developed, the growers have always succeeded in producing one wine of high quality. This is the Constantia, which has in it the guarantee, which no one seems ever quite to have accepted, that the Cape climate can bring to absolute perfection the essential vinous constituents of the Grape, which no other country is quite known to do, except the port wine growing district of Portugal. Roasting sun, good soil, and something else, probably a very dry, pure air, do this, and there always has been a district of the Old Colony where these natural qualities of soil and climate were so far appreciated as to make vineyard planting a staple industry. But it is one thing to grow Grapes for wine, and another to grow them for the table. At the present moment there are tons of little black vineyard Grapes arriving from the Cape. Their condition and taste are an object lesson both as to what the Cape can do and what it might do. These are of a first-rate flavour, but of all sizes, unthinned, crowded on the clusters, with many half-ripe inside the bunches. They are, however, pleasant to taste, and remind

the buyer of the days of vintage abroad. Their flavour is also evidence of how excellent they might be, if properly pruned and thinned. Later, in April, very fine white, or rather green, Grapes, grown well and carefully packed, come from the Cape. They are of medium size, of a beautiful clear green like chrysopræse. The flavour is not that of Muscat, but is excellent of its kind.

For early winter fruit the Cape also contributes varieties which are most welcome at that season. Figs ripen in November, and there is practically an unlimited market for fresh Figs in London. The Cape colonists are anxious to develop a business in dried Figs, so that they may rival Smyrna. The Karoo is looked upon as the future centre of Fig

FIG. 60.—TECOMA JASMINOIDES.

growing and drying. It is intended to introduce the Fig insect which assists in bringing the Smyrna Figs to perfection. But we think that before this industry is developed the trade in fresh Figs will be so large as to repay the growers. The price in this country, even in the natural season, is so high that there would be an immense margin for profit if they were offered here in December. In early winter Cape Strawberries and Apricots are in season together, the former being in perfection in November, while the latter last all through December. It is maintained that these Cape Apricots are, without exception, the best in the world. We have tried them both fresh, as delivered here, and preserved, and this experience, limited necessarily to a few cases, entirely bears out the claim made for the fruit. It is incomparable.

Loquats in October and Cape Gooseberries, a wild variety, which in the form of preserves is almost the best confiture in the world, make up the list of the best Cape fruits, and we have no hesitation in saying that these, when properly cultivated and of good varieties, are some 25 per cent. better than any other, except certain varieties grown in England and Western Europe under glass. It is worth remembering also that in addition to the happy accident of the Cape autumn occurring at a season which enables its fruits to be sent here in winter and early spring, there are differences of season in the colony itself. The first plateau, which runs all round the coast, produces its crop at an interval from that on the second plateau, while the roasting heat and drought of the Western

province cause a different season for the crop from that in which the table Grapes ripen in the East, where there are rains in November and February.

Nor are the Cape growers handicapped, as are those in the West Indies, by want of adequate steam service or easily reached markets. The huge increment of wealth in the goldfields has caused passenger lines to increase their steamers in number, size, and accommodation. These steamers, meant to carry those enriched by the goldfields, or those who in hope of being rich are careless of expenditure, are the ideal vessels for fruit transport—speedy, roomy, and furnished with ample cold storage. Yet Cape fruit, except the little black Grapes is very dear. It is still a costly luxury, not a popular delicacy. The Japanese Plums grown in South Africa were recently selling at 1s. apiece in Covent Garden, Cape Peaches were 1s. 6d. each, and Pears 8d. The quality of all three kinds was perfect, but they could only be regarded as specimen fruit. While the crop remains dear and uncertain it is not strange that little Cape fruit is yet imported, compared with the demand. The blame lies entirely at the doors of the growers themselves. Their Government is endeavouring to awaken Afrikaner opinion on the subject. They need teaching that only the best fruit is wanted here, that this must be carefully sorted, beautifully packed, so that in the package the fruit looks like a piece of decoration, or, at least, as fresh as when plucked, and that then the English public will pay a good price for it. At present the farmers are mostly too ignorant and indolent to do this. The fruit, as the Government botanist complains, is thrown into kerosene tins, or any chance receptacle, and sent off to be hawked about the local towns instead of being properly graded and sold in Europe and America. They should be taught the methods of California.

Unlike the Cape, California has no near markets, as at Cape Town and Johannesburg. The shortest journey is to Chicago, 2500 miles by rail, which costs £10 for every ton of fruit. New York is 3500 miles distant, yet tens of thousands of tons are sent by rail to each city. They also ship their fruit another 3000 miles by sea from New York to England, making 6500 miles in all, and they make this pay, though their season is the same as our own. If California had the season of the Cape, and could get its Peach and Grape crops into our market in the winter and spring, it would double its industry. But the organisation of the Californian growers is perfect. The Fruit Growers' Union, in "acre shares," so that the smallest and the largest owners are members, collects the fruit, despatches it, and finds a market. The Cape growers have only to study the Californian system of business and modern modes of culture, and Nature will complete an industry as valuable as the goldfields and more lasting.—("The Spectator.")

PRIMROSES AND POLYANTHUSES.

I AM exactly of the same opinion as "A. D." (page 220) with regard to the sowing and general treatment of these plants, and, like him, wonder at the unnecessary trouble some growers put themselves to in obtaining a stock of plants. There can be no question as to the relative advantage of autumn over spring sowing of Polyanthus seeds; especially is this true when it applies to indoor sowing.

I always make a point of sowing as soon as the seeds are ripe enough to gather from the plants, in drills sufficiently wide apart to allow of the ground being kept free from weeds. Old seed is very stubborn of germination, even when sown indoors; but with outdoor sowing of quite new seeds apparently every one germinates with regularity. By sowing in August, and the beds kept free from weeds, the resultant plants become sturdy and in fine condition for planting in their permanent or temporary quarters in April. The latter course is adopted when providing for the flower garden in autumn, several beds being annually furnished with them both in mixed and separate colours. For flower beds I find the large golden coloured sorts the most effective, as the mixed ones, though individually pretty and interesting, pale before the self-coloured flowers.

"A. D." correctly describes the method of autumn sowing and spring planting as simple and satisfactory: nothing could be more so. Plants intended for the flower garden in autumn are given the benefit of a shady border, one situated under a north wall, where their growth proceeds slowly, but surely, even in hot summer weather. The same border is reserved for the purpose every year, and is kept in a suitable condition by the addition of decayed manure and old potting soil at the time of or just previous to planting. After they have done duty in the flower garden they are thrown away, unless there are any of special merit and it is desired they should be retained for seed purposes. By making an annual selection of the finest it is easy to get an assortment of the best either in separate shades or in mixture.

The abnormally dry state of the soil, and the absence of water for daily watering of the seed beds, has resulted in smaller plants than I have had in any previous spring; but with fresh soil and showery weather they will no doubt make headway, and perhaps become quite large enough by October next. In the pleasure ground borders they will stand three or four years, the soil being somewhat heavy, and many positions shady; still blanks occur from one cause and another, and are made up from the annual sowing, either in autumn or spring. In light soils it would be necessary to plant stock plants in cool positions, or the tax imposed on them in seed-bearing would cause a partial if not a total collapse at the critical time. During tropical

weather, which invariably occurs during the seeding time, the plants flag badly when exposed to full sunshine. A mulching of the surface with short manure would sustain them materially during the summer months. Lifting and dividing is not worth the trouble, especially when seed saving and sowing is so simple. They reproduce themselves from seed fairly true to variety when planted in separate colours for the purpose.

It would be advisable in the case of any specially choice, which it is desired to perpetuate true to character from seed, that some means of protection be provided against insect fertilisation, muslin being as good as anything. For shrubbery borders, mixed colours afford the greatest interest, but for bedding separate colours, especially the yellow Polyanthuses, make the brightest display. Taking into account the ease with which they can be cultivated, and the floral feast made in summer, the wonder is they are not much more largely grown.—W. S.

THE YOUNG GARDENERS' DOMAIN.

YOUNG MEN'S DREAMS.

RESPECTING the article on page 99, to which "Thistle" refers on page 174, there certainly is much there that should demand the interest of the young readers of the Journal, and to some it might prove more useful than the reading of an article concerning the cultivation of a plant. I quite agree with "Thistle" that it would be better if all the young gardeners knew what was expected of them before they started gardening; doubtless it would save many a pang, certainly there would be less "weeds" of which to complain. But what of the amount of trouble involved in informing every beginner of the numerous items he would be subject to as a gardener? Only years of experience will convince him what gardening really is. I am of the opinion that not a few who start gardening do not enter into it seriously, and eventually awake and realise they have begun at the wrong end, or mistaken their calling.

Many of the young hands who are turned out of private gardens and nurseries have, I consider, a poor foundation for making a practical man, more especially should they solely follow the private garden. The reason for this, I think, is that having had about two years in the glass department, they prefer to continue indoors rather than seek experience in the kitchen garden or pleasure grounds, though there are, of course, exceptions.

When I first applied for a vacancy in a garden and asked for particulars, I was told to a willing lad there was plenty of work, and such I found to be true; but had I been told then that it would fall to my lot to assist in fitting hot-water pipes, and in planting acres of forest trees, another occupation might have been mine. However, I hope to see other remarks than mine in connection with young men's dreams, as it will give additional interest for the readers of the Domain.—PARVO.

BEGONIA MANICATA.

THIS is one of the fibrous-rooted Begonias which is oftener seen in a neglected condition than otherwise. When well grown, as it fully deserves to be, it makes a splendid plant for house furnishing during the winter and spring, with its glossy green foliage and tall spikes of small pink flowers. If good stout cuttings made from the leading shoots are inserted round a 48-pot in a light sandy compost, they will root readily in a night temperature of 60°. As they are of a succulent nature there is a danger of their decay if kept too close and wet at this stage. To get good plants for winter flowering the cuttings should be put in by the end of March. When well rooted transfer the young plants to a small pot, using a compost of three parts good-turfy loam to one of leaf mould, with enough charcoal and sand to keep it porous. A warm pit is suitable during the summer months, where they can have plenty of light and air. When thoroughly established a weak stimulant will prove beneficial in keeping the foliage a healthy colour and producing good stout spikes; a thin shading will be necessary during the hottest hours of the day.

In the autumn the plants may be given a light place in a vinery, the stove being too close and moist. Care must be taken in staging and removing the plants not to injure the foliage, or the appearance of the plants for decoration will be spoiled. With judicious feeding and top-dressing they will remain satisfactory a second season in the same pots. We have two such plants now in bloom, each carrying about two dozen spikes. They are, of course, rather straggling as regards the growth, but this we consider enhances their beauty, as formality is done away with, which is a thing to be desired from a decorative point of view.—M. I. P.

THE GLOXINIA.

GLOXINIAS are amongst the finest flowering plants that are used for the decoration of the stove during the summer and autumn months. Not only do they make a beautiful display, but the flowers are also valuable for cutting, and by potting at different times they may be had in succession for several months. Old tubers that are stored under the stage or elsewhere should be carefully examined, and any that show signs of growth must be brought from their resting place, leaving the dormant ones for succession. If there are no signs of growth, place the pots containing the tubers in a temperature of 65°, syringing them twice daily. As soon as they commence to grow they should be repotted, removing the old soil from the tubers and putting them into well drained pots, using a compost of equal parts of good fibrous loam, peat, and leaf soil, with a liberal addition of sand, keeping the top of the tuber level with the surface of the soil.

The tubers may be put into small pots and be moved as required, or they

may be put into their flowering pots at the commencement. By practising the latter method a saving of time is effected, and they do equally well. Stand the pots in a light but shaded position, and apply water sparingly until the roots have taken possession of the soil, when they will require an abundant supply, and the application of liquid manure once a week will be of great benefit to them. Syringe well every day to prevent an attack of thrips or red spider. It must be remembered that the Gloxinia is a shade and moisture loving plant, and care should be taken that these essentials are supplied.

In addition to potting the old tubers successionally, the season of flowering may be still further prolonged if young plants are raised from seed each year, as these under suitable management will form a succession to the old plants. Seeds may be sown in February or March in well-drained pots in a light sandy compost; cover very thinly, place a square of glass over the pots, and plunge in a bottom heat of 80°; keep them very moist and shaded until the seeds have germinated. When the seedlings are large enough to handle prick them off into pans, in a compost similar to that in which the seed was sown, replacing again in bottom heat, so as to encourage them to make as much growth as possible. Before the young plants become crowded place them into small pots, using a compost as recommended for the old tubers; put them in the stove, as near to the glass as possible to prevent them becoming drawn and weakly, and shade from sunshine; when they have made sufficient growth transfer them to their flowering pots, 4-inch pots being quite large enough.

As the leaves, both of the young and old plants, begin to turn yellow, water should be gradually withheld, but they must not be dried too rapidly. When all the leaves have died the tubers may be taken from the pots, freed from soil, and stored in boxes of cocoa-nut fibre refuse or sand in any dry place, with an even temperature of about 55°; or they may be allowed to remain in the pots, which should be laid on their sides under the stage of the greenhouse or stove. They must not, however, be allowed to get wet, or the tubers will either decay or start prematurely into growth, and such a state of things should be carefully guarded against.—S. P.

FRUIT FORCING.

Vines.—Earliest Houses.—Colouring will shortly be proceeding in the very early started houses. To insure well developed berries afford a thorough supply of tepid liquid manure, and mulch the border at once with an inch or two of partially decayed manure, preferably rather lumpy. Stable litter, having the strawy portions shaken out, thrown into a heap, and when commencing to heat turned over twice, forms excellent mulching material. This will give a stimulus to the roots and secure healthy foliage, while the moisture will be sufficient, in most cases, for the Vines until the Grapes are cut, but they must not lack water at the roots, as this will cause the premature ripening of the wood and the loss of the principal leaves, which may induce fresh growth when the Vines should be going to rest. Damping the house must be continued until the berries are well advanced in colouring, after which reduce the moisture gradually, and insure a circulation of warm air day and night by regulating the ventilation judiciously. The temperature should be maintained at 70° to 75° in the daytime, with a rise of 10° to 15° from sun heat, allowing the temperature to fall during the night to 65°, or even 60°.

Vines in Flower.—Afford a circulation of warm rather dry air, and a temperature of 65° to 70° at night for Black Hamburgs and similar varieties, and 70° to 75° for Muscats. The extra warmth draws out the bunches, aids the development of the flowers, and the potency of the pollen. Muscats and other shy-setting varieties should be brushed over with a camel's-hair brush about the time the blossom is fully expanded, so as to rid the stigmas of the caps and glutinous substance, choosing a warm part of the day after the house has been freely ventilated. This will render them fitted for fertilisation, which should be effected by brushing them over with a brush surcharged with pollen taken from such free-setting sorts as Black Hamburg and Alicante.

Succession Houses—Disbudding.—It is not good practice to attempt this until the bunches appear in the points of the shoots, and then it ought not to be done in a hurry, or a large reduction be made at one time. Proceed gradually and with determination, so as to give as little check to the Vines as possible. Retain no more shoots than can have the full benefit of light, as crowding is one of the greatest evils in Vine culture. Allow for the due extension of the laterals, for on this depends sustained root activity till the crop is perfected.

Stopping the Growths.—The bearing shoots should be allowed to extend in accordance to the space. If this is limited, the Vines being close, the shoot may be pinched at the first joint beyond the bunch, and this should be done when the leaf at the joint is the size of a penny. If there is a moderate space between the rods, allow two joints beyond the show for fruit. When there is abundance of room allow the shoots with fruit to extend three or four leaves beyond the bunches before taking out their

points, doing this when the leaf at the stopping joint is the size of a farthing. Laterals will push from the joints both above and below the bunches. Those below may be rubbed off except from the two lowest leaves, which should be pinched at the first joint; or if there is a good distance between the spurs on the rods all the laterals below the bunch may remain, pinching to one leaf. But laterals above the bunch may either be pinched to one joint, or allowed to extend until available space is fairly furnished; then pinch, and keep them within bounds afterwards by stopping to one joint as made.

Thinning.—This is a very important operation both as regards the bunches and berries. Remove all superfluous and duplicate bunches before they flower. Setting depends on the good form of the bunch, and on its receiving the essentials of fertilisation. Free setting varieties may have the berries thinned as soon as they are out of flower, but Muscats and other shy-setting varieties should not be thinned until it is seen which berries have been properly fertilised by their taking the lead in swelling. Every berry should have room to swell without becoming wedged, and yet leave enough berries to insure the bunch retaining its form when cut.

Watering, Feeding, and Mulching.—Until the Vines are in leaf they require very moderate supplies of water, sufficient only to keep the soil moist, but when the leaves are full-sized the evaporation from them is considerable, and from that time until the fruit ripens they must not lack water at the roots. It is difficult to state how often the borders will need watering, through their being so variable in dimension and formation. A narrow border will require watering twice as often as one double the width, assuming the Vines to be equally extended and cropped, while a border of loose materials will need water much more frequently than one formed of firm retentive loam. Consequently the grower must be guided by the state of the Vines in relation to the rooting area, and have due regard to the weather, as water will be required much oftener in hot, dry weather, than when cold and dull. The proper procedure is to examine the border, and when water is necessary give it abundantly. Surface dressings of artificial fertilisers are of much benefit for the health of the Vines and the swelling and perfecting of their crops. There are several advertised which are excellent, and may be applied, according to the instructions, at intervals of three to six weeks. A dressing may be given as soon as the Vines start into growth, a second when they are going out of blossom, another after the Grapes have been thinned, a fourth during stoning, and a final one when the Grapes commence colouring and are taking the last swelling.

Liquid manure is more prompt in action than a top-dressing, and may be supplied whenever watering is required, taking care that it is not too strong, and is warmed to the mean temperature of the house. Vines restricted to narrow borders will need higher feeding than those with large rooting areas, affording liquid manure whenever water is requisite, but it is well to change the food occasionally. A mulching of short, sweet, lumpy manure, as stable litter freed from straw, about an inch thick, and added to from time to time, so as to maintain that thickness, is excellent for ordinary borders, but those composed of light porous materials should have a mulching of well-decayed manure, as it lies closer, and the roots of the Vines are attracted to it through its retaining moisture better and longer.

THE KITCHEN GARDEN.

Globe Artichokes.—Plants of these not having been crippled by frosts are growing strongly, and suckers are exceptionally numerous. Remove the protecting material at once and thin the growths freely, as for cropping purposes three or four strong ones to a clump will do better service than greater numbers. Under starvation treatment Globe Artichokes are unsatisfactory. Remove the soil, to the extent of baring some of the root, to a distance of not less than 15 inches from the stems, and after dressing heavily with decayed manure, return the soil. The next best thing is to mulch with manure in April or early in May. These Artichokes may easily be raised from seed, either in gentle heat now or by sowing in the open ground next month, but rooted suckers from ordinary stocks are preferable.

Asparagus.—A heavy covering of manure keeps the beds cold and unduly moist, retarding growth accordingly. Comparatively dry strawy manure hovered over the beds does not keep the ground so cold, but yet serves to protect the points of the delicate shoots, many of which are injured by frost just as they are coming through the ground. Decayed manure should, then, be carefully removed, and the surface of the beds lightly loosened with forks. If the plants and roots are very near to the surface a top-dressing of 3 inches of fine light, moderately rich, soil will act beneficially. Where the plants are grown singly—that is to say, not less than 2 feet apart—the finest shoots are produced, and if blanched stems are desired a mound of fine vegetable mould should be drawn up and banked over each clump. It has to be moved with the hand when the shoots are traced out and cut, and returned after the cutting. Seeds may be sown now, or a fortnight later, and early next month; or just when top growth commences new beds may be formed with young plants.

Celery.—Plants resulting from seeds sown now in gentle heat should maintain the supply till next spring. Standard Bearer and other known hardy red or pink varieties are the best for present sowing. Very early raised plants are best moved twice before they are put out. By the time these are thoroughly rooted, beds, raised in preference to sinking trenches, should be ready for their reception. The finest exhibition Celery is in some instances grown in raised beds, kept together by means of stakes and boards. The plants are put out in a mixture of loam, garden soil, manure, and burnbake, and the blanching eventually accomplished by means of bandages of brown paper. Celery forms a good successional crop to Brussels Sprouts, Broccoli, and Borecole, and as the ground is cleared of

these the trenches may, with advantage, be got ready. Especially is early digging desirable where the ground is naturally of a clayey, bad working nature.

Lettuce.—Lettuces can be grown to perfection on the ridges between early Celery trenches. If a width of nearly 4 feet is allowed, there is room for a central line of Dwarf Kidney Beans and a row of Lettuces on each side, all coming off the ground before it is wanted for earthing the Celery. Well hardened Lettuce plants may be planted either on ridges or the flat, and more seed sown at the same time. Plants raised moderately early ought now to be large enough to prick out 3 inches apart in sheltered beds of good light soil. During a showery period slugs are troublesome, and are very plentiful this spring. They should be trapped under heaps of Broccoli or other leaves, and, in addition, frequently dusting the plants with soot and lime is necessary.

Sowing Peas.—If several rows of Peas are sown at one time they are apt to give pickings of pods also at much the same time. A good rule to follow is to sow one or more rows, according to circumstances, directly the plants resulting from the preceding sowing are coming through the ground. It is a mistake to crowd either the rows, or the plants in the rows. Allow room to develop, and admit light and sun to all. The rows should at least be as far apart as the known height of the varieties, and a pint of a good main crop sort is enough seed for a row 60 feet long. Open wide rather than narrow drills, and cover the seed with 3 inches of fine soil. Protect from slugs as advised in the case of Lettuce, and if birds are troublesome, either cover with galvanised wire netting, or strain a network of black thread over the rows of plants.

THE BEE-KEEPER.

SPRING DWINDLING.

DURING the early spring months bee-keepers are often perplexed owing to the comparative weakness of many of their stocks, which, instead of increasing in strength, gradually become weaker. They continue in this condition until a favourable spell of warm weather sets in. This, for want of a better name, is called spring dwindling. But what is the cause? The chief causes are old queens, shortness of stores, a damp or badly ventilated hive. It may also happen with a colony headed by a young queen introduced the previous autumn. This usually results when the hive is crowded with bees hatched during the summer months. These will survive the winter, but will succumb during the changeable weather usually experienced in early spring, and by the time the young queen has filled the hive with brood and bees the season will be well advanced.

In the case of old queens, which from various causes may not have been removed, the dwindling is more apparent than in the above, as she would not commence to lay for some weeks after a young queen had filled several combs with brood. This fact alone shows the advantage of having all colonies headed by prolific young queens.

Bees cannot be expected to increase in numbers if there is a shortness of stores in the hive. The same effect, however, may be caused by feeding late in the autumn, so that the bees have not sufficient time to seal their stores before the cold weather sets in or the temperature is too low for them to carry out this necessary operation. A damp or badly ventilated hive is more often the cause of spring dwindling than anything else. This may be quite unknown to the bee-keeper until it is too late. It is such a simple matter for the interior of the hive to become damp, owing to a leaky roof, and how can bees be expected to progress when in this unsatisfactory condition?

EARLY SPRING FLOWERS.

Owing to the mild winter and the favourable weather experienced of late, the early spring flowers already in bloom are somewhat numerous. But, strange to say, some are later than usual. For instance, the common Daffodil, which is plentiful round our apiary, is not yet showing the colour of the blossoms, whereas in some former years we have found blooms of this variety fully expanded at this early date. Probably the hot weather experienced last autumn is the cause of it. The Winter Aconites are now over. Bees were observed working on them in January. Snowdrops have been plentiful, and are not yet over; they have not been visited by the bees as freely as we have sometimes observed them. This was probably caused by the wealth of Crocuses, which have been a mass of bloom for several weeks past. These are visited by the bees more than any other of our early spring flowers, owing to the large amount of pollen that is obtained from them. Unfortunately sparrows are very fond of the blooms, and play havoc with them. In some districts this is so serious that their cultivation has had to be given up. The different varieties of Scillas are very showy, and are not neglected by the bees.

The common Palm Willow is now in bloom. From this the bees derive much benefit, as, like all the Salix tribe, it yields a large amount of pollen early in the season, and is much more valuable than the other varieties.—AN ENGLISH BEE-KEEPER.

TO CORRESPONDENTS

•• All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," 8, Rose Hill Road, Wandsworth, S.W., and NOT to 12, Mitre Court Chambers, Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *nom de plumes* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Lawn Patchy (E. W.).—We have never known half-decayed cow manure to kill grass, but the reverse. Of course, if applied too thickly it would smother the grass. If it be actually killed it would be advisable to sow the whole with seeds, not a mixture containing Clover, but of finest lawn grass seeds only, at the end of this month or early in April, choosing mild weather.

Potting Young Melon Plants (Idem).—In potting young Melon plants from the seed pan they should be sunk to within about half an inch of the seed leaves, or when they are leggy, about an inch. If the seedlings have been grown sturdily they will not have much more than an inch of stem, therefore the roots in potting will only be just covered with soil; very deep burying of a long stem is not desirable. We recommend the cordon system of growing in houses or on trellises, because we find it most satisfactory after trying it extensively.

Large Beetle (W. P.).—The fine specimen is the great water beetle, *Dytiscus marginalis*. It is quite harmless to vegetation, but voracious in both the larval and perfect state, even not sparing members of its own family. It may do harm to spawn and fry of fish, otherwise it is useful in keeping down insects that feed upon aquatic vegetation.

Leaves of Tomato Seedling Discoloured (R. L.).—The second leaves appear to be affected by what is termed "curl," which gives the leaflets a peculiarly twisted appearance, due to the tissues being in part injured or destroyed, and in some cases discoloured or browned. It has been attributed to "brunure," or browning disease. We, however, could not detect any trace in your plants of the parasite, hence consider the appearance due to sudden and excessive evaporation from the leaves. We can only advise more air, especially early in the day. There does not appear anything to be alarmed about, the plants being sturdy and apparently healthy in the stems. The roots, however, are rather browned, possibly by being out of the soil.

Grubs from Soil (W.).—The grubs are those of the so-called "fever fly" (*Dilophus vulgaris*). There are two broods, one appearing about May and the other in the early autumn. The larvae or grubs are both saprophytic and parasitic in mode of life—that is, they live on vegetable matter in a state of decay, commonly in both horse and cow manure, and on the roots of living plants, such as grass and corn in fields, roots of Hop plants, and Lettuces in gardens. The eggs are often laid in manure, and thus the grubs are introduced to the plants; but the flies also deposit eggs on ground rich in decaying vegetable and animal matter, we having found them abundantly in the mulching of Vine borders, but not, so far as we could make out, feeding on the Vine roots. The best remedy is gas lime, but it must only be used on bare ground. Half a hundredweight per rod should be spread on the surface evenly, and left there for a month or six weeks, then dug in with a fork. Where there are plants, such as roots of fruit trees or Vines, apply 1 cwt. per rod of best chalk lime spread evenly as soon as slaked, and dig in, not deeply, in the course of a few days, or not longer than a week, and always choosing dry weather for applying the dressing. We have also found kainit, 7 lbs. per rod, to act promptly on grubs of this kind, distributing evenly on the surface, and leaving for the rains to wash in. In the growing season finely powdered nitrate of soda stupefies and kills the grubs. Apply 1½ lb. per rod when the ground is moist, but with a prospect of fine weather, as then the nitrate acts better on the grubs, which are usually near the surface. The nitrate must be kept from the hearts of growing plants, especially when these are moist with dew or rain.

Improving the Colour of Ferns (T. E. R.).—It is usual for plants that "have been wintered in a low temperature at rest" to become pale in the fronds, as they have not developed any chlorophyll. With fresh growth the plants would no doubt improve in colour or become greener, but you may probably secure more colour in the present fronds by using clear, weak soot water, about a tablespoonful of soot to a gallon of water, allowed to settle before use, say for three or four days after mixing. Sulphate of iron or green vitriol, $\frac{1}{2}$ oz. to a gallon of water, has a good effect on the development of the chlorophyll, but must be used judiciously.

Monkshood Poisonous (Veritas).—The statement that "persons have swooned and lost their sight for some days through inhaling the odour of the flowers" of *Aconitum napellus* is not without foundation, as the circumstance is recorded in Dr. Hogg's "Vegetable Kingdom;" it is also there stated that four gentlemen were poisoned at Dingwall through a servant ignorantly digging a root of Monkshood and serving it at dinner for Horseradish. The leaves of the plant are also poisonous, though goats and horses are said not to be injured by eating them. Having regard to the facts recorded, we should not consider it prudent to grow the plants, as in your case, close to a dwelling, where children might innocently eat the leaves or take a strong smell of the flowers. We have grown the plant for years without any accident occurring, but they were not in positions to which children had free or ready access, or near beds of Horseradish, where the roots might be accidentally dug up and used.

Temperature for Maidenhair Ferns (S. B.).—The term "Maidenhair Ferns" embraces the whole of the species and varieties of the genus *Adiantum*, but is frequently applied to the common Maidenhair, *Adiantum capillus-Veneris*, with its varieties, which is a native of Great Britain. It succeeds in a greenhouse or even a frame, hence would thrive in the position you describe, but is not nearly as useful for decorative and cut purposes as that more generally grown—namely, *A. cuneatum* and its charming form, *A. gracillimum*. *A. cuneatum* will succeed in a greenhouse, better in a warm one or cool stove, and is a native of Brazil. By keeping comparatively dry in winter the plants might be grown in the greenhouse, but they would then be at rest, for which they are all the better, and would give very useful specimens for decorative purposes and fronds for cutting; yet, as you say, in the summer months only. To have fronds in winter time it requires a temperature of 55° to 60° at night, and 60° to 65° by day, with 5° to 10° more from sun heat. In summer time the temperature rules 5° to 10° more all round in a cool stove.

Artificial Manure for a Lawn (A. B.).—The advertised lawn manures are excellent, and save the trouble of procuring separately and mixing the articles. If the latter, there is probably no better than Sir J. B. Lawes' and Sir J. Gilbert's mixture: Sulphate of ammonia, eight parts; kainit, five parts; sodium silicate, four parts; superphosphate, four parts; sodium sulphate, one part; and magnesium sulphate, one part, mixed, using 7 lbs. per rod on a rough lawn, and half that quantity on a lawn neither coarse in grass nor very mossy. If the latter, add a part of sulphate of iron to the mixture, thus making twenty-four parts, and still use at the rates named. The fertiliser should be applied in advance of sowing the renovating mixture of lawn grasses, so as to allow the salts to pass into the ground—say sow the mixture of manure a fortnight previously. For the new lawn we should use the lesser quantity of the mixture, or $3\frac{1}{2}$ lbs., adding this amount of native guano, mixing, and sowing a few days before the grass seeds, and raking in. Or use a similar quantity of rape meal instead of the native guano, especially if likely to be troubled with wireworm.

Spotted Pelargonium Leaves (W. W. B.).—The sickly spotted appearance of the Zonal Pelargonium leaves is caused by the fungus, *Ramularia geranii*, which is assisted in germination and development from spores by a wet condition of the soil and a somewhat cold damp atmosphere. There is no remedy, as the growth of the parasite is endophytic, the mycelial hyphæ being situated in the interior of the leaf tissues. Very lightly dusting the plants on the under side of the leaves with a preparation of sulphate of copper in powder, such as fostite, which has been advertised in our columns, arrests the spread of the disease, but the main points to attend to are a drier condition at the roots and in the atmosphere. No more water must be given than suffices to keep the foliage from flagging, and the ventilation should be free, so as to dissipate moisture before the sun acts powerfully on the foliage. With finer weather or the season more advanced the plants will, at least they usually do, grow out of the disease. The worst infested leaves should be removed and burnt, but do not practise extreme defoliation. A gentle warmth, about 50°, by day, would be an advantage to the plants.

Exhibiting Rhubarb (Secretary).—You are quite right. There was a slight mistake in the hurry for press in the reply to "Young Gardener" on page 226 last week. It would have been more correct to have stated that Rhubarb is exhibited as a vegetable, but used as a fruit in the form there mentioned, and sweetened with sugar. For the purpose of exhibition Rhubarb is properly classed as a vegetable in the R.H.S. "Rules for Judging." It is there stated that the "stalks should be fresh and well coloured, straight, uniform, and of medium size;" also that if included in a collection of vegetables to be judged by points 4 shall be the maximum—2 for size and uniformity, and 2 for colour and freshness. If lacking in any of the four qualifications—size, uniformity, colour, or freshness—points, or half points, would be deducted accordingly. We have said that Rhubarb when shown is "properly" classed as a vegetable, because there cannot be a fruit without a flower to produce it, and flowers are not seen on the leaves or stalks of this useful culinary plant. The late Dr. Hogg's definition was concise and sensible—namely, "Rhubarb is a vegetable used as a fruit." It is said that our American cousins compromise the matter by referring to Rhubarb as the "pie plant."

The Shamrock (Ireland).—The plant sent (*Trifolium minus*) is the generally accepted Shamrock of Ireland, but old authorities believe that the original Shamrock is the Wood Sorrel (*Oxalis acetosella*). An early writer (Sir Henry Piers) says, "Between May Day and harvest, butter, new cheese, curds, and Shamrocks are the food of the meaner sorts." Now Wood Sorrel is an agreeable salad herb, whereas Clover or Trefoil, which is usually considered as the Shamrock, is anything but palatable. Then Fynes Morrison writes of his countrymen, "They willingly eat the herbe Shamrock, being of a sharpe taste." A description applicable to the Wood Sorrel, but not to any species of *Trifolium*. Moreover, the Clovers never grow in woods, whereas the Wood Sorrel has there its native place, and coincident with this the "Irish Hudibras" states:

"Within a wood near to this place
There grows a bunch of three-leaved grass,
Called by the boglanders Shamroques,
A present from the Queen of Shoges (spirits)."

These authorities, we think, justify the conclusion that originally the Wood Sorrel was the Shamrock of ancient times.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (C. S.).—1, *Polystichum viviparum*; 2, *Pteris cretica albo-lineata*; 3, *P. tremula*; 4, *Adiantum Farleyense*; 5, *Pteris longifolia*. (P. H. B.).—1, *Forsythia suspensa*; 2, *Rivina humilis*; 3, *Erythronium dens-canis*. (D. T.).—1, *Mahonia aquifolia*; 2, *Andromeda floribunda*; 3, *Cotoneaster microphylla*; 4, dead. (J. C. C.).—1, *Adiantum pedatum*; 2, *Asplenium lucidum*; 3, *Polypodium angustifolium*; 4, *Nephrodium molle*; 5, *Nephrolepis davallhoides furcans*; 6, *Davallia canariensis*. (L.).—*Marica (Cypella) gracilis*.

THE FRENCH DAIRY INTEREST.

We are so apt to consider the Danes, and the Danes only, as our great rivals in the production of dairy delicacies, that we overlook the other nations who have turned their attention to this particular industry. We must correct ourselves. In southern England, those parts nearest Normandy, there is some knowledge of French enterprise. Of course it is natural that perishable goods should be landed at the nearest port, so we on the east and northern coasts are more conversant with Danish wares than we are with those of "La Belle France."

From early Norman days these two countries, separated by a silver streak, have been more or less antagonistic. We have scoffed at and despised the "Mounseer," and he has made game of "John Bull." First one of us, and then the other, has had the advantage, but, on the whole, affairs have been pretty evenly balanced, and we can neither give each other great odds. Indeed, when we consider how much Norman blood runs in our veins, it is no wonder we are in many things so much alike. Climatic influences bring about the differences, but racially we are in a measure one.

The enterprise of the Frenchman does not stop at butter and cheese, he actually has the audacity to send us over milk; but it is not with his milk exports we are at present concerned, it is more his butter and his cheese. The writer of to-day, a man at home equally on an African "veld" as on a Norfolk pasture, does not give, as an eye witness, the most pleasing accounts of the butter and its surroundings as found in Brittany.

The custom appears there for the butter to be gathered up from all the small farmers (peasant proprietors) and then re-made, worked, and blended in a manufactory. Well, that is not quite our idea of the way to make good butter, but this mixture or manufactured article finds a ready market. We should not like the raw material. The French farmhouses and surroundings (the small ones we mean) are not arranged with much idea as to sanitary matters, and the people themselves are too hard pressed by constant toil to be ultra-particular about the methods employed.

We should prefer that the manufactories began with the milk rather than with the already made up butter; there would be more chance of rudimentary cleanliness at any rate. In northern France we find a good class of cow, very much after the stamp of our Shorthorn, and it is to these northern provinces that we look for butter production. The grass land of Normandy is sound and good, well calculated to produce milk, and also well calculated to produce grand well-developed cart horses. The principal butter districts are the departments of Ille et Vilaine, whence come 18,000,000 lbs. of butter; Nord, touching on Belgium, Pas du Calais, and further west, Calvados and Manche. This butter is sold by the kilogram, equal to 2.2 lbs., and the price varies from 1s. 3d. to 2s. 4d. per kilogram, just about what most English farmers get for theirs. We do not often fall below 7½d. per lb., and do not often exceed 1s. 2d., although we see that for two weeks in August we actually made 1s. 4d., and in October and November 1s. 3d. (This was owing to the prolonged drought, which caused great scarcity of food).

France produces yearly somewhere about 136,000,000 kilograms of butter as against Denmark's 50,000,000, and Italy's 16,500,000. But after all it is not in butter production that France exceeds the other nations—she takes the lead in cheese, and gives us cheeses many and varied. The working classes of France have always been much more frugal than the same class in England. They live more carefully and on a plainer diet, vegetable soups, salads, any bread but wheaten, no beer, and not much meat, not half the luxuries that the British workman demands.

Of all forms of food nothing is much more concentrated than cheese. It may be a little hard of digestion, but when that is accomplished the system is enriched by many valuable constituents. The Englishman does not put cheese quite in its right place, he uses it as a finish to his meal rather than making it the *pièce de résistance*. Cheese is not consumed by the working classes as it used to be. In our young days most farmers made at least a few cheeses to be used

for himself and his men, and now, except in the cheese districts proper, where is the cheese-maker? Gone with the home brewer and bread maker.

Cheese used to be sent out always for afternoon luncheon in harvest, and filled many a gap at other times; now cheap pork pies and cakes take its place. The French are very proficient in soft cheese manufacture—the taste for these goods is certainly growing in England, but slowly. Our dairy teachers are now prepared to show us how to make many varieties of small inexpensive cheeses, but the market is not quite here yet. We stick to our hard varieties, and for a change in summer enjoy a real cream—an expensive luxury only for the few.

Like the hard or pressed cheeses the soft ones can be made either plain or rich. It is simply a question of removing the cream, and for immediate consumption the plain cheeses are most excellent. They are made up into small shapes, easy of purchase, easy to consume, and form a most pleasing variety in the menu. Whether we as a nation shall ever take the matter up seriously remains yet to be proved. France makes £2,500,000 of her hard cheese, but a good deal more of her soft cheese. When the English palate is sufficiently cultivated, perhaps the English farmer will be found ready to put on the market such and similar varieties known abroad as Brie, Loudom, Miers, and Camembert.

WORK ON THE HOME FARM.

Farmers are renowned as grumblers, but the man who would grumble at the present weather must indeed have a soured mind. We had just a sufficiency of frost, though not too much, some nice rain, which has invariably fallen in the night, and so hindered no work, and now we are enjoying bright sunshine and a June temperature.

Barley is being sown under perfect conditions of soil and temperature, and there is now quite the full regulation supply of March dust. Wheat is being rolled and harrowed; some fields are much too thick of plant, and harrowing is necessary for thinning purposes.

Where top-dressing for Wheat is thought necessary it is time the manure was put on. If sulphate of ammonia be used it should be sown immediately without delay, as it is so much slower in its action than nitrate of soda. Nitrate may be sown until the end of April. Salt can be put on the Wheat, and will do good on sandy soils; 4 to 5 cwt. per acre.

Clover seeds may now be sown, and if the land be clean and as free from weed seeds as it ought to be, they had better be sown with the Barley immediately after the corn drill. This is the only sure and certain way of attaining a good plant of seeds.

Farmers who can spare time from the spring sowing are doing a little more to the fallows; we see the smoke of twitch burning in several directions to-day. Thus thousands of little bits will be utterly destroyed which, if left, would have quickly made the land as foul as ever.

Lambing proceeds satisfactorily, and, generally speaking, losses are very small, both ewes and lambs being exceptionally healthy. Young seeds are looking very green and fresh, the Rye grass providing a nice bite for the ewes with pairs, which are now being favoured with the first taste of it. Turnips are nearly done, and the fat hogs are quickly going to market, leaving a poor look-out for the supply of the April fairs.

The beef trade is better, and store beasts are making good prices, good yearlings making up to £9 and £10 each. We see that anthrax is again reported from North Lincolnshire, two farms being affected. This sounds very serious, as one is the second outbreak within a few months, and we should sympathise with the occupiers in what must be a very prolonged time of anxiety.

12th.—Fair day, with bright sunshine at times.

13th.—Foggy morning, with the sun visible; bright afternoon.

14th.—Fog all day, generally rather dense.

15th.—Fine and sunny day; haze or slight fog in morning.

16th.—Overcast all day; wet fog early and most of the morning.

17th.—Smoke fog nearly all day, and lights necessary, but clearing towards sunset.

18th.—Overcast, with occasional drizzle in morning; fine, and frequently sunny, after noon.

Fogs early, much bright sun, no rain, and temperature near the average.—G. J. SYMONS.

BARR'S GOLD MEDAL
DAFFODILS
 The Most Lovely
 of all Spring Flowers.

Barr's Prizes for Daffodils.

AN ELEGANT SILVER CUP,

Specially designed by H. G. MOON, is offered by us for Competition at the following Exhibitions:—

APRIL 5th & 6th.—At the Spring Show of the ROYAL CALEDONIAN HORTICULTURAL SOCIETY, Edinburgh.

APRIL 12th.—At the Spring Show of the ROYAL BOTANIC SOCIETY, Regent's Park, London.

APRIL 13th & 14th.—At the Daffodil Show of the MIDLAND DAFFODIL SOCIETY, Birmingham.

APRIL 18th.—At the Daffodil Show of the ROYAL HORTICULTURAL SOCIETY, London.

Full particulars of the Competition can be had on application to the Secretaries of the Societies.

BARR'S NURSERIES, LONG DITTON, SURREY
 (Near to Surbiton Station, L. & S.W. Ry.).

VISITORS INVITED

To see the grand display of Daffodils in bloom during April.
 We shall be pleased to advise intending visitors when the Daffodils are at their best.

A constant display of Daffodils is also maintained during April at

12 & 13 KING ST., COVENT GARDEN, LONDON

RIVERS' FRUIT TREES, Roses, Vines, FIGS, ORANGES, AND Orchard-House Trees.

A LARGE AND SELECT STOCK
 ALWAYS ON VIEW.

ILLUSTRATED AND DESCRIPTIVE CATALOGUE,
 Post Free, 3d.

THOMAS RIVERS & SON,
 SAWBRIDGEWORTH, HERTS.
 HARLOW STATION, G.E.R.

To Nurserymen, Builders, Local Bodies, Vestries,
 AND OTHERS WHO INTEND
 PLANTING TREES AND SHRUBS THIS SEASON.

ROBERT NEAL, F.R.H.S.,
 THE NURSERIES,

319, TRINITY ROAD, WANDSWORTH, S.W.,
 Begs to offer an extensive Stock of FOREST and
 ORNAMENTAL TREES, SHRUBS, ROSES, GRAPE
 VINES, FRUIT TREES, CLIMBING PLANTS, &c.,
 which, being grown in the neighbourhood of London, are
 especially suitable for Town Planting. DESCRIPTIVE
 CATALOGUE FREE.

HIGH CLASS

NURSERY STOCK.

LAURELS for single bushes, splendid heavy broad plants (not thin or weak), every one a specimen; all well rooted and with good foliage, of the hardiest varieties (no tender Common Laurels included), 2 to 2½ feet, 25/-; 2½ to 3 feet, 30/-; 3 to 4 feet, 35/- to 50/- per 100.

Thinner Plants for Covert Planting, &c., 2 to 3 feet, 16/-; 3 to 4 feet, 25/- per 100.

PORTUGAL LAURELS, very fine, 2 to 2½ feet, 6/-; 2½ to 3 feet, 9/- and 12/- doz.

AUCUBAS, well-coloured, well-rooted plants, mostly as wide as they are high; fine for ornamental grounds; stand well under trees; fine shrub for smoky situation, and if planted with male Aucubas beautiful for berries; 12 to 18 inches, 6/- doz.; 18 to 24 inches, 9/- doz.; 24 to 30 inches, 12/- to 18/- doz.; 30 to 36 inches, 18/- to 30/- doz.; cheaper by the 100.

HOLLIES, green, splendid pruned specimens, mostly furnished to the bottom, from 5 to 10 ft. high. This is a grand stock which every buyer of Hollies for ornamental grounds, screens, tall hedges, &c., should see. Prices on application.

HODGINS and other ornamental green-leaved varieties, and Silver variegated, same sizes and in equally fine plants, probably the finest stock of Hollies in the Kingdom.

RETINOSPORA AUREA, Broad Pyramids, each plant a model, 12 to 18 inches, 9/- doz., 60/- 100; 18 to 24 inches, 15/- doz., £5 per 100. Cupressus and other Conifers in great variety. For List Prices and Descriptions—

SEE CATALOGUE.

CLIBRAN'S, ALTRINCHAM & MANCHESTER

ASPARAGUS.—This delicious vegetable does not require half the expense usually incurred. For simple instructions see SEED LIST, free on application. Strong roots from 2/6 per 100.—**RICHARD SMITH & CO.**, Nurserymen and Seed Merchants, Worcester.

PENTSTEMONS, PHLOXES, ANTIRRHINUMS.—For the best of these and all other sections of FLORISTS' FLOWERS and HARDY PLANTS, see Forbes' Illustrated Catalogue, 152 pages, free on application.—**JOHN FORBES**, Nurseryman, Hawick, Scotland.

IMPORTANT TO MUSHROOM GROWERS.—**CUTHBERT'S SPECIALITE MUSHROOM SPAWN.** Always alive; most productive. Hundreds of Testimonials. Per Bushel, 5/-.—**R. & G. CUTHBERT**, Seed, Bulb, and Plant Merchants, Southgate, N. Established 1797.

ALL WHO WISH GRAND RESULTS should use **THOMSON'S IMPROVED VINE, PLANT and VEGETABLE MANURE.** This valuable Manure is yearly growing in public favour. Can be had of all Nursery and Seedsmen, or direct from the makers, **WM. THOMSON and SONS, Ltd.**, Tweed Vineyard, Clovenfords, Galashiels, N.B. Price Lists and Testimonials on Application. 1 cwt. and upwards Carriage Paid to all stations in Britain and Ireland. London Agent—**Mr. J. GEORGE**, 14, Redgrave Road, Putney. Agent for Channel Islands—**Mr. J. H. PARSONS**, Market Place, Guernsey. Also **THOMSON'S SPECIAL CHRYSANTHEMUM MANURE.** ½ cwt. Carriage Paid to all Stations in Britain and Ireland.

STANDEN'S MANURE.—Established over 30 years, the strongest and most perfect fertilizer in the market, only very small quantities required to obtain the best results, thus rendering it by far the cheapest manure on offer, analysis on application. In Tins, 1/-, 2/6, 5/6, and 8/- each, and in Kegs, ¼ cwt. 10/6, ½ cwt. 18/-, 1 cwt. 32/-. Proprietors.—**CORRY & CO., Ltd.**, Finsbury Street, London. Sold by all Seedsmen.

PURE WOOD CHARCOAL, Specially Prepared for Horticultural use. Extract from the *Journal of Horticulture*: "Charcoal is invaluable as a manurial agent; each little piece is a pantry full of the good things of this life. There is no cultivated plant which is not benefited by having Charcoal applied to the soil in which it is rooted." Apply for Pamphlet and Prices to the Manufacturers—**HIRST, BROOKE & HIRST, Ltd.**, Leeds.

GARDEN NETTING, small mesh, keep out the smallest birds, oiled and dressed; will not rot if left out in all weathers. 105 yds. by 1 yd. wide, 3/-; by 2 yds. wide, 6/-; 105 yds. by 3 yds. wide, 9/-; and so on to any width; carriage paid on all orders over 5/-. As supplied to the Royal Gardens. Commoner Netting, 50 square yds. for 1/-. I do not require payment until you have received and approved of the Netting.—From **H. J. GASSON**, Garden Netting Works, Rye.

VINE CULTURE UNDER GLASS.—By **J. R. PEARSON**, The Nurseries, Chilwell, near Nottingham. Price 1/-; post free, 1/1. Fifth Edition. OFFICE, 12, MITRE COURT CHAMBERS, FLEET STREET, E. C.

GREENHOUSES from £3 5/-; **VINERIES**, **CONSERVATORIES**, **FRAMES**, **SUMMER HOUSES**, &c. Illustrated List Free. Makers to **H.M. THE QUEEN** and **H.R.H. THE PRINCE OF WALES.**

POTTER, HAWTHORN & CO., London Works, READING. (Name Paper.)

Journal of Horticulture.

THURSDAY, MARCH 30, 1899.

THE JOURNAL OF HORTICULTURE can be obtained from the Office, 12, Mitre Court Chambers Fleet St., London, post free for a Quarter, 3/9. Editorial communications must be addressed to 8, Rose Hill Rd., Wandsworth, S.W.

THE FLOWING TIDE.

WHO has not stood by the seashore which surrounds our island home, and watched the waters of the mighty ocean swelling and pressing onward as the tide comes in? Its movements are as fickle and erratic as the weather of an April day; sometimes the surface of the waters shows but little movement beyond the natural swell of the flowing waves, at others the waves run high, the surf is dashed in fitful fury in all directions, and the roar of rushing waters inspires us with feelings of awe for the power and grandeur of our land's defender. Yet through all these changes the course is onward, ever onward till full tide is reached.

How great may be the simile between our own lives and the ocean's daily movements of flowing and ebbing tides. As the gardener passes through the various seasons of the year, each bring their pleasures and their difficulties; sometimes the latter are as pronounced and sudden as the rushing waters of the ocean, and need the grit of the true British Oak to withstand their force, yet the course is plain—onward, still onward, till the goal is reached. A goal that brings pleasure with it, in the consciousness of good work accomplished, and a good fight won.

With the advent of spring begins the flowing tide of the gardener's year, and in proportion, as opportunities are grasped as they arise, will the varying degrees of success be achieved. From the beginning of the year till now the chief signs of activity in vegetable life have been confined to the inmates of glass structures; but all nature is now awaking in the open air, and each day brings with it fresh evidences of the return of spring, even though winter may obstruct it sternly. Fruit trees on walls are in many places already in flower, in others they are ready to unfold their buds; if left to themselves one night's frost may ruin the prospect of success, and provide cause for lamentation for the whole year. Those who are fortunate in having plenty of canvas or tiffany in readiness may, by the aid of a few poles placed against the walls, soon make the flowers secure from frost,

even when the expense of coping boards and pulleys is not incurred, though the latter arrangement is preferable on account of the ease with which the coverings may be drawn up or lowered as required. Unfortunately, however, in many cases the necessary materials are not provided in time to be effectual.

After a sharp frost it is a good plan to let the trees remain covered till near noon, when they are in position which the sun catches early in the morning, as many instances might be recorded in which both plants and fruit blossom have, after being slightly frozen, been saved from ruin through warding off the sun's rays. It is not always the frost alone which does the damage, it is the rapid change from cold to heat which causes scald. Spruce boughs or fronds of bracken fastened over trees in flower in cases of emergency will often prevent disaster, and a plentiful supply of these materials are useful for many purposes in spring.

We may, perhaps, some day find out a way of protecting fruit trees in open quarters from the devastating effects of frost which occur while they are in flower. When we do there will be a good time in store for the British fruit grower. The resourceful Americans seem to be stealing a march upon us in this respect, for they have long been trying experiments in that direction. Their plan of procedure is to light fires in their orchards during the evening when sharp frosts are expected.

The fires are made of green brushwood and other rubbish which burn slowly, and they claim to be able to arrest the lowering of the temperature of the air around their fruit trees by several degrees, through checking radiation by the cloud of smoke, which is also provided in the morning to prevent the injurious effect of sunshine after frost. This seems at least to be a plucky attempt at grasping an opportunity. I wonder if any British fruit grower has tried the plan? It was, I believe, borrowed from continental Vine growers.

Turning to the kitchen garden we find hosts of important matters requiring attention while the conditions are favourable for the work. The land is in that beautifully dry crumbling condition so favourable to seed sowing. Onions and Parsnips should have been sown several weeks ago; if not done the work ought to be attended to at once, though in the case of Onions such late sowing paves the way for a bad attack of maggot, as the young plants do not have time to grow out of the critical stage before the egg-laying flies are hatched out. It is true they cannot always do so, but it is wise to give them a chance.

Successional Peas, Beans, and Spinach will also need sowing, and the main crop of Carrots. Where there are warm sunny borders, early stocks of Lettuce, Cabbage, and Cauliflower will be making good progress if the soil is kept frequently stirred during sunny days, and other sowing need be made in similar position. Cauliflowers planted in open quarters should be set in drills, and have refuse placed around them for protection; if these are allowed to remain till the present spell of cold nights has passed, removing them when the weather is open, it is surprising how little a few degrees of frost will affect them. Slight protection where possible seems to be the golden rule to observe with so many spring crops in our treacherous climate. There is also the great work of Potato planting. Many early ones have already been "committed" to the soil, and will perhaps later on feel the keen touch of a May frost; but it is always a good plan to plant some of the early varieties at the end of March or early in April, and throughout the latter month every opportunity should be taken to plant both midseason and late kinds till the whole of such work has been completed.

To lay a sure foundation upon which to rear success in vegetable culture, the autumn and winter work of deep digging must be practised, but it is not less important that work should be kept well in hand during the spring; and while taking advantage of favourable opportunities for sowing and planting, the frequent stirring of the soil to let in warmth and keep weeds in check, must not be neglected, if the tide of spring promise is to flow onward to a bountiful harvest.—ONWARD.

LÆLIO-CATTLEYA ERNESTI PRINCESS OLGA.

At one or two of the more recent meetings of the Royal Horticultural Society, Mons. Ch. Maron of Brunoy, France, has been represented by some superb hybrid Orchids, and on February 28th amongst others exhibited was *Lælio-Cattleya Ernesti Princess Olga*, which is admirably depicted in the woodcut, fig. 61. This bigeneric hybrid came from a cross between *Lælia flava* and *Cattleya Percivaliana*, and is of exceptional beauty. In form, substance, and colour it is well nigh perfect, and every visitor to the Drill Hall was charmed with this superb addition to the Orchid family. The colour is a rich yellow with a deeper suffusion in the sepals and petals, the latter being comparatively broad and wavy at the margins. The splendid lip is crimson, paler at the edges. The Orchid Committee recommended a first-class certificate to the plant, which we understand passed immediately to the collection of Mr. Norman C. Cookson.

LÆLIA FLAVA.

THIS little Brazilian species, although not so showy as some of the larger *Lælias*, is well worthy a place in any collection, on account of its clear, shining, yellow colour. To the hybridist it has proved invaluable, as by its aid such valuable hybrids as *L.-C. Princess Olga* and *L.-C. Myra* have been raised. The former is a hybrid between *Cattleya Percivaliana* and this species, and the latter a cross with *Cattleya Trianae*. It succeeds under the same conditions as *L. cinnabarina*, which it resembles, only it is much smaller, therefore should be hung close to the glass in the intermediate house.

LÆLIO-CATTLEYA BELLA.

This beautiful hybrid is now in flower, and although one of the first to be raised by Mr. J. Seden it is still one of the most charming, but, unfortunately, is still very scarce. It is a cross between *Lælia purpurata* and the old stock of *Cattleya labiata*. The flowers are large, quite 10 inches across, the sepals and very broad petals being of a rosy lilac colour, and the lip over 2 inches across, with a broad anterior wavy lobe of rich purple or lake, with a lighter purple disc. The colour is white, tinged with rosy purple at the side, and at the mouth of the tubular portion of the lip are two oblong zones of yellowish white, and in front of them two spots of the same colour. This, like many other fine hybrids, was first flowered in the collection of Baron Schröder, The Dell, Staines. The treatment given *Lælia purpurata* will answer its requirements admirably.

BULBOPHYLLUM BARBIFERUM.

This curious and interesting plant is again pushing its fascinating flower spikes, and to the lover of botanical curiosities will be of great interest. I have found it succeed in the warmest house the whole year, with a good supply of water during active growth, and a reduced quantity when at rest. It will succeed in the ordinary Orchid compost, in small pans or baskets suspended close to the glass. It comes from Sierra Leone, and is well grown by Mr. White, who has charge of Sir Trevor Lawrence's collection at Dorking.

DENDROBIUM RUBENS GRANDIFLORUM.

This, one of the best of the *D. Lecchianum* and *D. nobile nobiliss* crosses, was raised by Mr. J. Cypher of Cheltenham. It is a very fine flower, being nearly 4 inches across, and the petals almost 1 inch in width, of a peculiar rosy purplish crimson. The finely feathered lip is extremely beautiful, and the plant is a worthy companion to *D. n. nobiliss*.—J. BARKER, *Hessle*.

LÆLIA DIGBYANA HYBRIDS.

THE set of hybrids raised from *Lælia (Brassavola) Digbyana* and sundry of the *labiata* *Cattleyas* are very beautiful plants, each showing the delicately fringed lip of *L. Digbyana*, more or less delightfully tinted. The first of these appeared some ten or twelve years ago, and is the result of a cross effected by Mr. Seden in Messrs. Veitch's nursery, the other parent being *Cattleya Mossiae*. The pseudo-bulb and leaves are most like those of the *Lælia* parent, but without the peculiar grey tinge; the flowers are large and very handsome, the sepals and petals are a pretty soft rose tint, the latter much broader than the former.

The lip is a beautiful feature, broad and massive, the outer portion and the fringe a little lighter in colour than the sepals and petals, but having more or less of a deep crimson streak in the open portion. There is then a large white central area leading to the golden yellow throat, from which lines of an old gold tint lead to the under side of the column. The parentage of the other *Lælio-Cattleyas* raised being

very similar to this one, the description generally tallies with them, but there are differences, as will be noted. The next on the list was also raised by the same successful hybridist, who in this instance used *C. Trianae* as the seed parent.

L. Digbyano-Trianae was exhibited before the Royal Horticultural Society in 1897, when a first-class certificate was deservedly awarded by the Orchid Committee. This is an even more beautiful plant than the last, having more colour, though of course its general characteristics are similar. Then in April of last year Messrs. Veitch exhibited a third, *L. Thorntonii*, though this pretty plant was not raised in the first instance in their nursery, but by T. W. Thornton, Esq., after whom it was named. It is not equal to any of the preceding, still a lovely plant, its second parent being the summer-flowering *Cattleya Gaskelliana*. The fringed lip is again beautifully reproduced, but the colour is less bright.

A very beautiful plant is *Laelia Digbyano-purpurata*, the parentage being represented in the name. This, though showing its affinity to *L. Digbyana*, has not the same delightful appearance as the rest, the influence of the strong-growing *Laelia* being apparently too much for the weaker one. In shape it resembles *L. purpurata*, and the lip is light purple in front with a very narrow fringe only. And now the latest addition is from quite a different source, having been exhibited at the Drill Hall on March 14th by Mons. Chas. Maron of Brunoy, France. The beautiful *C. Mendeli* has been used here in conjunction with *Laelia Digbyana*, and very pleasing indeed is the result.

The radiating lines of yellow so prominent in *C. Mendeli* are reproduced, and there is something about the white frilling at the upper part of the lip that reminds one of this fine species. A great many other species have been used as seed parents, and in more than one large establishment seedlings in various stages of development can be seen. Of these, of course nothing can as yet be said, but the present day custom of using only the finest types of each species for hybridising purposes will have its effect, and we may look forward to their flowering with interest at least, and a considerable amount of confidence.

DENDROBIUM WIGANÆ.

This is one of the finest of hybrid *Dendrobiums*, and a lovely form of it was that shown at the Drill Hall on March 14th by Sir Trevor Lawrence. Many of the forms recently flowered have shown a certain amount of yellow in the ground colour, but none that I have seen have been so fine as this chaste form, which was named *D. W. xanthochilum*. A remarkable point about this hybrid is that it was raised by Sir F. Wigan, Sir Trevor Lawrence, and by Messrs. Veitch & Sons, Ltd., at, or about the same time, and it is to the credit of all concerned that it was only once named. It is the result of crossing *D. nobile* and *D. signatum*, and first flowered in 1896.

ANGRÆCUM CITRATUM.

Though very small in comparison with such giants as *A. eburneum* and *A. sesquipedale*, this is a very pretty and chaste plant. It takes its name from the colour of its flowers, which when growing in a state of nature are pale citron yellow, so we are told. Under cultivation this colour wholly disappears, or at most is only a cloudy white. Looking at a number of plants of it in full flower recently, I could not find a trace of yellow on the sepals or petals, so the name is rather misleading. The racemes are often 18 inches or more in length, so make a pretty show when in flower.

The culture of *A. citratum* is not difficult when plenty of heat and atmospheric moisture is at command. Being of small stature the plants are not at home in large roomy receptacles; they like being pinched as it were for room, and the best thing to use is the small wire baskets about 4 inches across for single-stemmed plants. Two or three large lumps of charcoal may be placed in the bottom of each, and a little more mixed with clean freshly gathered sphagnum moss for compost. Fix the plants firmly, using a few strands of matting if necessary, though this will be seldom. Water must be freely given all the year round, and light sprayings overhead serve to keep the plants healthy and free of insects. It is a native of Madagascar, discovered there early in the present century by M. du Petit Thouars.

A NOTE ON DENDROBIUMS.

There are few more popular genera of Orchids than *Dendrobium*, and none more beautiful. If a grower were tied to one house of Orchids, those to be of one genus, he would probably get more beautiful plants and more variety out of it by growing them than by growing any other. The lovely golden tint of the evergreen kinds, like *D. densiflorum* and others; the showy hybrids raised from our old friend *D. nobile*, *D. aureum*, and many others; the lovely *D. phalaenopsis*, and others of the New Guinea kinds, to say nothing of the most popular class of all the long-stemmed deciduous groups, of which *D. Devonianum*, *D. Pierardi*, and *D. Wardianum* are well-known examples. Of quaint and fanciful forms there are plenty, such, for instance, as *D. taurinum*, *D. stratiotes*, and others, and although they lack to some extent the grace and elegance of the deciduous kinds, there are chaste and fine flowers among the nigro-hirsute groups.—H. R. R.

FARM ORCHARDS—IMPORTS AND PRICES OF APPLES.

WE take the following extract from a paper read at a farmers' club by Mr. Spencer U. Pickering, F.R.S., Director of the Duke of Bedford's Experimental Fruit Farm at Woburn. As might be expected, the paper, which was read by Mr. Pickering at a recent meeting of the Royal Horticultural Society, was of a different character, and from what we hear, it appears to have been too scientific to meet the approval of some of the audience. However that may be, there is evidently a practical side in the mind of the scientist, for this is what he said to the farmers:—

"I am not aware of the conditions under which the old farm orchards were originally planted, but the conditions under which they are now generally renewed are the most unfavourable which could be devised. To plant a young tree in ground which is probably exhausted by having supported a similar crop for a century or more, in ground still being drained of whatever good it contains by the spreading roots of large neighbouring trees, is, to say the least, unfair treatment. In addition to this, dead wood, both above and below the surface, abounds, and affords a supply of every parasite which is likely to injure a tree,

FIG. 61.—LÆLIO-CATTELEYA ERNESTI PRINCESS OLGA.

and the young trees can rarely obtain a proper supply of light and air through the network of branches of the older ones; while, even if properly secured to stakes and sufficiently protected from the onslaught of the farm stock, the trees too often come to grief through the fall of rotten branches from their old neighbours.

"When advocating a little more attention to orchards we are always met with the stock objections of low prices, foreign competition, and high railway rates; these are, I fear, generally urged rather as excuses for not making exertions, than as valid reasons against fruit-growing. In the case of soft fruits there certainly are occasional gluts, when it does not pay to gather or market ordinary orchard produce, but with Apples, good fruit of good varieties, when properly marketed, will always pay for carriage and yield a good return. I need only quote my own experience in Bedfordshire. In years of plenty Apples are hawked about the country at 1s. 6d. to 1s. a bushel, having been obtained from farm orchards where the grower probably did not receive more than a quarter of these prices for them; yet at the same time we can send properly grown Apples to Covent Garden and obtain a return of 4s. to 8s. per bushel, sufficient to pay carriage and all other charges, leaving a substantial profit for the grower. Foreign competition scarcely affects soft fruits at all at present, and with the hardier fruits its effects are but small, owing to the bulk of such fruit arriving in the market after the English fruit has for the most part been disposed of.

"The enormous quantities of Apples which are now imported into England from abroad have, so far as I can ascertain, had but little effect on the average prices realised. The public taste for fruit seems to be eminently capable of cultivation, and the market for fruit is consequently a very expansive one. I have attempted to obtain accurate statistics as to the amount of the importations and the

average prices during the last twenty or thirty years, and also data showing the amount of land under fruit in England throughout this same period—which latter would show how far this increased demand has been responded to by English growers—but without success, and I fear that such data as have been collected are not applicable for this purpose.* The annual importation of market Apples, however, during the last ten years amounts to from three to six million bushels, and is probably equal to or greater than the total amount of English-grown Apples marketed thirty years.

"There is no doubt that we have lost markets which might have been captured, and are likely to lose others, which are at present scarcely affected by foreign competition. For this, I fear, we have only ourselves to blame. It is in the fruit trade, as in almost every other, our want of adaptation to the requirements of customers, and our obstinate adherence to traditional practices, however antiquated, which lead us to be ousted by the more observant and painstaking foreigner. The careless way in which English fruit is generally picked and handled before it is sent to market is sufficient to prevent it from ever realising high-class prices, and the niceties of grading and packing it, so that it may not only travel without damage but present a tempting appearance to the purchaser, are almost wholly unknown to English farmers. It is lamentable to walk through Covent Garden Market and see the prices asked for foreign Apples and Pears, and compare them with those fetched by the generality of English produce, especially when we know that—as regards the former at any rate—we can produce fruit equalling, if not excelling, any foreign produce, both in quality and appearance, while we have all the advantages of short distances to the market."

But here come the causes—the complaint against the railway rates, which are "no doubt capable of improvement in favour of the grower; but those who inveigh most strongly against them, and contrast the rates paid for sending English produce a short distance with those paid for foreign produce, are apt to forget that small packages of fruit sent occasionally cannot possibly receive such favourable treatment as large and regular consignments. Cases have also come under my knowledge of railway companies having taken the initiative in trying to induce farmers to adopt some sort of co-operation for placing goods on their line in bulk, so as to secure lower rates, and I may notice the instance of the Great Eastern Railway Company taking the initiative in helping small producers by supplying wooden boxes at a cost less than that at which they could be made, except in a large quantity. I am glad to learn, through the courtesy of the Company, that this step seems to have been appreciated to a marked extent, and that the annual sale of these boxes now reaches nearly 130,000."

THE BEST PEACHES.

THE variety Dymond I have never grown under glass, but have invariably found it excellent on the open walls. It bears well, and the fruits are large, handsome, and of the best quality. Waterloo has proved the best of the earlies, Early York and Hale's Early following with Dymond and the midseason varieties, then Gladstone, Sea Eagle, and Princess of Wales as the latest. With regard to flavour, much depends on the management of trees and the way they are cropped. It is my practice, and has been for some years, not to crop merely for quantity; fewer fruits, larger in size, and better in flavour, should ever be kept in view.

As yet I am at a loss to know the real cause of Peach trees when early forced shedding a portion of their buds. Even when the golden rules are strictly adhered to the buds will drop more or less. We have been told that lifting the roots and relaying them in fresh soil nearer the surface will in a great measure prevent the malady. One does not dispute this, but if the borders have been properly made, the compost suitable and sweet, the depth 2½ feet, surely the roots should be safe and right for some few years and require no disturbing. Then we are told if the trees be subjected to too high a temperature when starting them into growth the buds will fall, and so they will at times, no matter how careful you are and have been, which satisfies me that the mischief is done before the starting time. Goshawk I must not omit to mention, as it is a first-class Peach.—H. MARKHAM, *Wrotham Park, Barnet.*

* "Since the above was written I have received, through the courtesy of Major Craigie, of the Board of Agriculture, a collection of data relating to the amount and value of imported fruits, from which I have drawn the following summary as regards Apples:

	Bushels imported.	Value.	Value per bushel.
1883—1890 inclusive.....	22,509,195	£6,268,585	5s. 8d.
1891—1898	33,218,561	9,457,891	5s. 8½d.

"Thus, when these two periods of eight years are compared with each other, we find that the imports have increased by 50 per cent. without appreciably affecting the value per bushel. At the same time, however, I must remark that these data are deserving of a more careful analysis than it is possible to give them here, and that any general conclusions drawn from them without such an analysis should be accepted with some reservation, especially as the 'values' are those declared by the consigners, and not the prices realised in the market.

KINGSTON CHRYSANTHEMUM SOCIETY.

At a meeting of the Committee of this Society, held on Friday evening last, to revise the schedule for the next November show, the Chairman, Mr. W. Drewett, was enabled to announce that Sir J. Whittaker Ellis, High Sheriff of Surrey, not only had consented to become the President for the year, but would also, for himself and Lady Ellis, offer a prize of 5 guineas. It was later agreed to make this sum the first prize in the miscellaneous group of plants class, and should help to create severe competition. Arising out of what took place last year, the Committee agreed to bar from the class all such accessories as cork and mirrors. It was also agreed to introduce a dinner table class for lady amateurs. The champion class now to be for thirty-six Japanese, distinct, instead of the old cup class for Japanese and incurved, entrance into which was a costly item, will now be open to all at one-half the previous charge. It was further agreed to retain the old "incurved" classes, but practically leaving to exhibitors their own interpretation of the term, quality still being the leading element, and also to introduce a class for recognised incurved Japanese, and a similar one for Japanese reflexed, in the hope that these may help to arouse greater interest in the Show. The Committee fully realised that constant repetition of the stereotyped classes leads to monotony and to stagnation. It is hoped, therefore, that the introduction of new features will in this way help to arouse new interest in the Society's exhibitions.

EUCHARIS AMAZONICA.

HAVING read the *Journal of Horticulture* for twenty-five years I must admit nothing gives me greater pleasure than to see a few lines appear respecting the cultivation of this plant. I am at one with Mr. J. Shalford in his able article on page 162. What with loam, leaf mould, decayed manure, sand, soot, paraffin and water combined with consideration, we are as strongly fortified as the "mite" itself. To follow the method Mr. Shalford adopts will, I think, put us in a fair way to do just as we please in respect to flowering the *Eucharis* at any season of the year. I have had to do with the *Eucharis* plant a few years longer than I have had with the *Journal*, but still I read the *Journal* first and attend to the *Eucharis* plants as soon as possible afterwards, as by so doing I think I am more likely to steer clear—by the valuable hints now and again thrown—of the dreaded mite.

The present time, perhaps, is opportune for me to give an account of the only *Eucharis* plant under my charge at present. I may say that when I took charge of these gardens a little over two years ago I found at one end of a span-roofed house a pot about 8 inches in diameter, over the sides of which were hanging a few dead leaves. I could see it was nothing more than a pot of *Eucharis* in trouble, so determined to kill or cure. I procured an old round-mouthed shovel, which I took to the field, dug a turf, and placed it on the fire till it was nearly red hot. I next went to where a fire had been burning a few days previously and secured some charred ashes, then some sand and soot, all of which were thoroughly mixed. It was very dry, so I took a two-gallon canful of water, into which I put two wineglassfuls of paraffin, and watered the compost through a rose until in a fit condition for potting.

Then the supposed dead plant was fetched, knocked out of its pot, and eight or nine bulbs, minus of roots, were disclosed. I examined them through my glass, and could see a number of very small white grubs. I placed them in a rather strong solution of paraffin and water for ten minutes, and afterwards in pure water for the same time. They were then put in a 10-inch pot, with the result that growth soon commenced, and at the present time I am pleased to tell you the plant is looking the picture of health, carries splendid foliage, and is promising to give a good display of bloom in the coming season. As I adopt Mr. Shalford's culture with the exception, perhaps, of one or two instances, such as watering at the roots with paraffin and soot water, also syringing over the foliage with this mixture, I think success is bound to follow. To my mind nothing is more pleasing to the gardener than to see the beautiful spikes rising from this plant, as the blooms are so valuable.

And now I would speak a word about a good *Eucharis* grower. On April 23rd, 1885, page 337, are some notes from my pen, and the plants then referred to have been seen many times since, as also has the grower, who looks almost as well as his plants. However, I must be content to say that at Cardiff Castle Gardens there are six of the finest plants of *Eucharis* I ever had the pleasure to see. I once happened to just catch them at their best, and they put me very much in mind of a snowstorm when the sun was shining. The plants were monsters, and I require no further proof that Mr. Pettigrew is a thorough master in the art of *Eucharis* culture.—H. MITCHELL, *Druidstone.*

RECENT WEATHER IN LONDON.—Several cold and heavy showers fell on Saturday afternoon and evening. Sunday was bright and fine with cold north and north-east winds. Since Monday it has been brilliantly fine and distinctly milder.

— WEATHER IN THE NORTH.—The past week has been one of wintry rigour. Beginning on the 19th with 6° frost, the 24th showed 14°, the cold intensifying daily. A slight shower of snow fell in the afternoon of that day; Saturday brought a heavy fall of fully 5 inches. Thaw set in on the afternoon, and continued with steady drizzle all Sunday. Monday afternoon was fine, and a west wind rapidly cleared off the snow. Greater depth of snow and harder frost are reported from several districts. —B. D., *S. Perthshire*.

— HESSLE GARDENERS' SOCIETY.—Mr. G. Wilson, Swanland Manor, read a paper before a moderately attended meeting of the above Society on Tuesday, the 21st inst., on "Cottage Gardens and Allotments." Mr. F. Mason presided in his usual manner, and the ensuing discussion was entered into by Mr. G. Picker, Hesslewood; Mr. Barker, West Hill; and several other members. The usual votes of thanks to the essayist and the Chairman brought a pleasant evening to a close. —J. T. B., *Hessle*.

— APPLE NEWTON WONDER.—This is the age of novelties and new introductions, and when any flower, fruit, or vegetable possesses high quality it is not long in becoming universally popular. Newton Wonder is not an old Apple, neither can it now be called a novelty, but so good are its qualities that in a comparatively short time it has secured a place in the forefront of popular Apples. The market grower has found out its worth, and Newton Wonder is now represented in many plantations, so that in a few years' time we may expect to find it among those sorts which are sent to market in bulky quantities. The other day I was shown a sample of Newton Wonder which had been grown in a Kentish plantation. Though late in the season for Apples, the fruits were firm and sound, large, and highly coloured; proving that not only does this variety succeed well in the south, but that it is one of the sorts capable in every way of competing with foreign produce. —V. T.

— A PERSISTENT PEA ENEMY.—In his interesting notes on Peas (page 211) Mr. Shalford makes reference to the damage done by the mischievous sparrow when the crop is nearing perfection. There is a worse pest among the feathered tribe than the sparrow, and lucky are those growers who have never been troubled with it. I refer to the hawfinch, a beautiful bird of the bullfinch type, which seems to be confined to certain localities. It is not the leaves that the hawfinch seeks, but the peas themselves, and its short thick strong beak might have been intended by Nature for the express purpose of shelling Peas. In localities where hawfinches abound they will frequently make a set at a row of Peas just when ready for picking, and if not checked at once they will soon clear the row. Their impudence is only surpassed by the sparrow, and they soon get used to anything in the shape of scares. The gun seems to be the only efficient means of checking their depredations in districts where they abound. —H.

— CAMELLIAS MATHOTIANA AND MATHOTIANA ALBA.—There can be no question as to the superiority of these two varieties, more especially the latter, which it is to be regretted is comparatively little grown in this country. It is said that it is somewhat difficult to cultivate, consequently that may be one reason as to its rarity. Such a reason, however, would seem to be illusory, if the two fine and flourishing examples I noticed a short time ago growing in the grand long corridor attached to the range of Orchid and other houses at Whetstone, Edgbaston, the residence of G. H. Kenrick, Esq. They were both profusely in flower, and the fair glossy foliage and substantial, deep, and creamy white petals of the latter were most attractive, forming also a distinct and pleasing contrast to the pure white colour of an adjacent fine specimen of *C. alba plena*. It may also be observed that about a score of similar fine specimens of other kinds of Camellias ranged along the whole length of the corridor in question present, either in bloom or otherwise, a pleasing effectiveness, and they reflect much credit upon Mr. J. V. MacDonald, the expert head gardener. —W. G.

— MINIATURE ZINNIAS.—Everyone who has had experience with these charming flowers—and what gardener has not?—will readily endorse all that "R. J." says on page 215 about their beauty, usefulness, and ease with which they may be grown. The writer of the article made no reference to classification, and perhaps the majority of Zinnia growers confine themselves to the tall growing section. I notice, however, that a new departure has been made in favour of dwarf Zinnias, and some seedsmen are offering them under the name given in the title. It is stated that the habit is dwarf, sturdy, and compact, and the flowers comprise such colours as white, crimson, scarlet, purple, and yellow. Such being the case, doubtless the miniature Zinnia will prove valuable for planting in positions not suitable for the taller growing kinds. —G.

— SWEET ALYSSUM.—Simplest of flowers! How often is its usefulness overlooked for bedding purposes? For forming edges, growing in clumps, mixing with scarlet "Geraniums," and a score other uses *Alyssum maritimum* is well worth its place. The pretty white flowers, produced in great profusion, are very pleasing, as also is the graceful habit of the plant. A packet of seeds will produce a stock of plants, and I have found the propagation from cuttings a good way of providing for the future. My practice is to raise a quantity of young plants from cuttings in small boxes in the summer. These are placed on a shelf in a cool house during the winter, and the following spring they provide ample cuttings for bedding later on. Plants raised from cuttings I find flower more freely, and do not grow so robustly as those grown from seeds. Sweet Alyssum is among the most accommodating of plants, and succeeds well in positions unsuitable for others of a more tender character. —H. R.

— THE CHELSEA BOTANIC GARDENS.—It is announced that the trustees of the London Parochial Charities have come to the rescue and saved the "Physic Garden" from the ruthless hands of the builder. They have agreed to devote a sum of £800 yearly for its maintenance, which the Apothecaries could not afford. Under the new scheme the garden is to be administered by a representative Committee exclusively for the promotion of the study of botany, with especial reference to the requirements of general education. Earl Cadogan represents Sir Hans Sloane, who conveyed the garden in 1722 to the Apothecaries' Company in trust for the purpose specified. The Garden was, however, founded in 1673, and the manor was purchased by Sir Hans Sloane, who gave the site, a freehold of 4 acres, to the Company on the conditions that they should pay £5 a year for it, and that the demonstrator of the Company should in their name deliver annually fifty new species of plants to the Royal Society until the number amounted to 2000. The presentation of plants continued until 1773, when 2500 species had been contributed. The first great Curator of the Garden was the celebrated Philip Miller, the last the diligent and respected Thomas Moore.

— PRESENTATION TO MR. THOS. TURTON.—When it became known that Mr. Turton was leaving Maiden Erleigh to go to The Gardens at Sherborne Castle, Dorset, a feeling was manifested amongst his numerous friends that the occasion presented itself to show the high esteem and regard in which he was held. With this object in view a Committee was at once formed, with Mr. J. Woolford as Chairman, Mr. J. Pound, jun., Hon. Secretary, and Mr. Jas. Martin, Hon. Treasurer, and the result of their labours was shown on the 22nd inst., when Mr. and Mrs. Turton met a few of the Committee in the committee room of the Abbey Hall to receive from the hands of Mr. C. B. Stevens (the President of the Gardeners' Mutual Improvement Association), the presents set forth in the following address:—"Your numerous friends join in offering their hearty congratulation on your important appointment to the position of head gardener at Sherborne Castle. At the same time they are conscious of the great loss the Reading District will sustain by your departure from Maiden Erleigh. In the prominent position you have occupied as Chairman of the Reading Gardeners' Association and as a member of the Committees of the Reading Horticultural and Reading Chrysanthemum Societies, horticulturists have had the benefit of your knowledge and wide experience. Especially do the younger men feel indebted to you for wise guidance and assistance on numerous occasions. It has been felt that your departure cannot be permitted without an expression of the high regard entertained for you as a successful exhibitor, a generous comrade and a true friend, and you are now asked to accept the accompanying gold watch and chain with a purse of money as a token of good-will and esteem from those friends whose names are hereafter appended. We also beg Mrs. Turton's acceptance of a tea and coffee service. We again heartily wish you continued success in your new sphere of labour." There were upwards of one hundred subscribers to the testimonial, which was highly appreciated by the recipients.

The week has been very cold, with strong north-westerly winds; snow fell on the 21st, and rain on the 25th.

— **SEVERE FROST AT WOBURN FRUIT FARM.**—At the lowest part of the farm we registered an extremely low temperature this morning (March 22nd), which is fortunately a rare experience at this time of year. A severe frost yesterday was followed by a snowstorm of about two hours' duration, and the temperature began falling rapidly shortly afterwards. The air was very still and clear, and this morning a tested radiation thermometer on the ground registered, minus 2.8° Fahr., nearly 3° below zero. The buds of Gooseberries are very advanced, and are likely to suffer. Pear flower buds are also forward, but not open, and the same remark applies to Plums, while Apples are in a quite safe condition. The elevation above sea level is about 260 feet, and the position of the thermometer is near a running brook.—R. L. CASTLE, *Woburn Experimental Fruit Farm, Beds.*

— **THE WEATHER AND FRUIT PROSPECTS.**—During the past week the weather has been of a very wintery character. On several nights the temperature has been very low. On the 21st 19° of frost were registered. In the afternoon a heavy snowstorm passed over, and in the short space of an hour upwards of 4 inches fell, followed by 19° of frost. The trees and shrubs were wreathed with snow, and the landscape had more the appearance of midwinter than spring. Under the circumstances the snow was beneficial as a protector of the crops, but fears are entertained that Peaches, Nectarines, and Apricots on unprotected walls have suffered a good deal, though most kinds of hardy fruit blossom is in a backward state, except a few Pears. Large breadths of Potatoes have been planted in the neighbourhood of Sandy. For several nights the frost has been so severe that for a time most kinds of outdoor gardening was at a standstill.—G. R. ALLIS, *Old Warden Park, Beds.*

— **MARCH FROSTS.**—Everyone interested in fruit culture will look forward with deep anxiety to hear of what effect, if any, of a disastrous kind has been exercised on fruit buds and the all too early blossom by the recent severe, and, for March generally, intense frosts. Were we to judge of what the effect has been by what is seen on the expanded blossom of Almond, we should assume that the harm done has been great. But there is wide distinction between what is seen on expanded blossom and on that which is yet so far sheltered by bud scales and undeveloped. But whilst the intense frosts have been for us in March somewhat unusual visitations, we may be assured that they are far from being such in North America; and if there the blossom eventually opens quite unharmed, why not ours here also? There has been, too, in our favour unwonted dryness, both of air and of soil; indeed, in reference to the former, we seem to have had conditions very much resembling those of North America, and dryness of the air does very much to mitigate the effects of the frost. Then, in spite of the saturation the soil received through the earlier part of the winter, it is now generally very dry. That, again, is an important factor in the matter, and it has much to do in creating so dry an atmosphere. No doubt the organs of fertility in fruit, the flowers, so sheltered in the undeveloped buds will endure much frost, because, as we all know, the chief harm is done when pollen grains, pistil, and ovary are in expanded flowers first exposed to moisture and then to sharp frosts. If any bloom has suffered, probably it will have been the expanded flowers on precocious wall trees, but even with these it often happens, that whilst open blossom is killed, unopened flowers escape. So far, however, all is conjecture; well may we hope that any harm done may be of the smallest.—ALEX. DEAN.

— **THE RAISER OF ERICAS WILLMOREI AND HYEMALIS.**—Mr Willmore's gardener, the late Mr. Williams, Harborne Road, Edgbaston, instead of, as stated on page 214, Miss Willmore's gardener at Strawberry Vale, was the reputed raiser of the Heaths in question—excepting, however, that there appears to be a doubt as to the real origin of *E. hyemalis*.—W. G.

— **READING GARDENERS' ASSOCIATION.**—At the fortnightly meeting of this Association on Monday evening last "The Arrangements of Hardy Plants in the Garden" was the subject of a lecture given by Mr. A. Wright of Falkland Park, South Norwood, when Mr. C. B. Stevens presided over a good attendance of members. In introducing the subject, Mr. Wright pointed out that no branch of gardening was so important as that of the arrangements of plants in gardens. Many practical hints were given. An animated discussion followed. A vote of thanks was proposed and carried unanimously.

— **BOURNEMOUTH GARDENERS' ASSOCIATION.**—A lecture on the *Primula* (Chinese Primrose), illustrated by lantern views, was given on Tuesday evening before a large attendance of members by Mr. James Martin, from the firm of Messrs. Sutton & Sons, Reading. Mr. Martin, in the course of his lecture, referred to the progress made in the cultivation of this useful winter-flowering plant since its introduction in 1819, and by the aid of the lantern (manipulated by Mr. Cox) forcibly demonstrated the great improvements made by cross-fertilisation, resulting in a great variety of colour, from the purest white to the deepest crimson, as seen in the New Crimson King, introduced for the first time this season. He also drew attention to the star or stellata form of this flower; a reversion to the original type, but which, on account of its graceful habits, is now becoming a favourite variety. He regretted to say that many gardeners were neglecting the *Primula* and other winter-flowering plants in favour of the *Chrysanthemum*, and which he thought was being overdone to the exclusion of other useful flowers. Mr. Martin, who is a most able and entertaining lecturer, concluded with some practical remarks on cultivation. A cordial vote of thanks was passed to Mr. Martin, Mr. Cox, and Messrs. Sutton & Sons for the interesting and instructive lecture.

NOTES ON MELONS.

THE earliest plants from a sowing made at the beginning of January, planted out at the beginning of February, and duly attended to in a light well heated structure, have the fruits set or setting on the first laterals. A rather drier atmosphere, and no more water than to prevent flagging, with an increase of temperature of about 5°, and a circulation of warm air, are desirable during the setting period. The flowers should be fertilised every day when fully expanded; pinch out the points of the shoots one or two joints beyond the fruit. When the fruits are set, and about the size of a Walnut, give the bed a thorough watering, and in a day or two add soil to the sides of the ridges or hillocks, pressing it firmly, and again supply water. Both the soil and the water should be of the same temperature as the bed. Stop the subsequent growths to one or two joints, and prevent overcrowding by rubbing off shoots from which there is not room for the foliage to have full exposure to light.

If the bottom heat be kept steady at 85° the fruits will swell all the better. Do not overcrop the plants, but leave the fruits proportionate to the vigour—two on weakly, three or four on vigorous, and very strong plants may carry six fruits. The night temperature may be 65° to 70°, 75° by day, ventilating from that point, increasing to 85° or 90°, closing between those heats, and sufficiently early to increase to 90°, or 95°, or 100°. Damp the house in the morning, syringe moderately by or before three o'clock on bright warm afternoons, damping the paths and walls in the evening. Keep the evaporation troughs filled with liquid manure. Plants in narrow beds will require plenty of liquid nourishment, always an advance of the mean temperature of the house, and top-dressing of rich material.

The growths on successional plants should be trained regularly, removing every alternate lateral, rubbing them off directly they are perceived, the remainder being trained to the right and left of the main stem. Pinch out the points of primary growths after they have extended two-thirds of the required distance. Increase the supply of moisture both at the roots and in the atmosphere as the days lengthen, but avoid making the soil sodden or the atmosphere saturated constantly with moisture.

Pot seedlings directly they show the first rough leaf, shading until re-established. Stop plants for pits and frames at the second rough leaf; those for trelliswork should have a small stick placed to each, securing loosely, and rubbing off the laterals while small up to height of the trellis. Transfer to larger pots as required, not allowing them to become rootbound, but plant out as soon as the roots are well hold of the soil and showing round the sides of the pot. Sow more seeds to afford plants according to the demand. Plants from seed sown now will give excellent results grown in frames after clearing them from forced Radishes, Potatoes, &c. In pits and frames a bottom heat of 80° should be secured to plants that are growing freely, renewing the linings as required. In newly made beds the bottom heat should be about 90°.—GROWER.

AN AMATEUR'S REMINISCENCES.

[On reading the spring number of "our Journal," with its "portraits of some famous writers of the past, and of some veteran contributors," I was stirred by an irrepressible impulse to send a few reminiscences of one of the "veteran readers" of the time-honoured publication, which, under its original name of the *Cottage Gardener*, gave me my first book knowledge of "the purest of human pleasures."

It is now forty-seven years since I purchased my first number of the *Cottage Gardener*. I was then a young man contemplating marriage. Though born and bred in a large manufacturing town I had a large quantity of country blood in my body, for my father and mother were both natives of one of the most rural parts of Worcestershire, as were their parents and grandparents before them. They both possessed ingrained country tastes, which survived, spite of the many antagonistic tendencies and influences of town life. I was thus fortunately surrounded by many things, the result of these country tastes, which the bulk of townspeople in those days had few opportunities of being acquainted with. For instance, my parental home was always brightened with well-grown window plants, which were the admiration of everyone who saw them; we usually had cut flowers in the living rooms; and we kept poultry and pigs. I thus had from my earliest days a loving familiarity with plants and flowers, and knew the taste and goodness of new laid eggs and home-cured bacon.

My parents had many country relatives and friends at whose houses and farms I usually spent my holidays from school; and these good-natured people kept us well supplied with all sorts of country produce, which arrived by coach or carrier in well-remembered hampers—poultry, honey, and fruit. Doubtless my surroundings and daily experiences had a share in giving me a taste for country life and pursuits, though heredity, probably, had quite as much, if not more, to do with it. Anyway, it seems to me quite natural that I should have made up my mind to possess a garden as soon as I commenced housekeeping and had a house of my own.

Looking forward to the possession of a garden some day, I, as a matter of course, felt that I ought to know something of the management of one. But the problem was "How to get this knowledge?" Present day readers will probably think this a rather silly question, for to them the obvious answer would be to get a good manual and subscribe for the "Journal." Ah! but in those far off days there were practically no such books as there are now; and what townsmen fifty years ago knew anything about gardening weeklies? Even then, however, two such publications had commenced their long careers of usefulness—"The Gardeners' Chronicle" and the *Cottage Gardener*, but I had never heard of either.

Among my friends I had the good fortune to possess one who, as I afterwards found, was one of the best amateur gardeners of his day. He was one of the earliest men to advocate the establishment of village flower shows; and I cannot help thinking that the *Cottage Gardener* had much to do with the worthy part he took as a pioneer in that work. He was a subscriber from the issue of the first number; and it was from him I learned of its existence, and on his recommendation that I became a subscriber in the year 1852. Later on he gave me a complete set of bound volumes, from vol. i. to vol. xiii. From that time I read the *Cottage Gardener* sedulously, and from it gained all my earliest ideas about gardening. Bit by bit I slowly acquired knowledge, for the articles were many of them written with special reference to the needs and requirements of those, who like myself, knowing nothing about the subject, earnestly desired to know everything.

Much as I have read since about gardens and gardening, I still look back on the articles which appeared week after week from the pen of dear old Donald Beaton and his revered fellow workers with the warmest appreciation of their interest and merits, and think they gave me more pleasure than anything has done which I have read since. The writings of "D. B.," from their suggestive unusualness, originality, practical value, and quaint humour have always had a special charm for me, and I shall always regard that worthy old man as my first master in the refining art of gardening.

It did not take me long to find out that I should understand the articles in the *Cottage Gardener* to more purpose if I knew more of the technology and technique of the subject; hence I was early led to buy another work by the contributors to the *Cottage Gardener*—namely, the "Cottage Gardeners' Dictionary." Thus equipped I made enough progress in theoretical knowledge to make one yearn for personal acquaintance with some good gardener, so that I might have the chance of seeing something of practical work. Now, among my country friends was one who farmed somewhat largely on the estate of the late Sir William Smith, of Eardiston, in Worcestershire, and the worthy baronet had a fine garden in the heart of one of the fruit-growing districts of that beautiful county. During one of my summer holidays my farmer friend made me acquainted with his landlord's head gardener, Mr. John Miller, the elder brother of a still more

famous gardener, Mr. William Miller, whose recent retirement from Combe Abbey Gardens was chronicled by the gardening press a few weeks ago. This worthy man gave me my first introduction to high-class gardening. The cultivation of dwarf fruit trees in gardens, especially Pears, had not long before been introduced by the late Thomas Rivers of Sawbridgeworth; and in the Eardiston gardens I saw numbers of such trees finely burdened with handsome fruit, of which Mr. Miller was very justly proud. It was no doubt the sight of these trees at a very impressionable period of my life that gave my mind a bias towards outdoor fruit growing, the pursuit of which has been one of the greatest pleasures of my life.

In March, 1854, I entered into possession of my first garden. It was situated in a pleasant village outside of the town of my birth, and overlooked a finely wooded park, now alas! covered with roads and houses. A more neglected plot of ground I never saw. The ground was trampled hard, as though it had been a playground, and it possessed neither tree nor plant of any kind, except a few weeds. Its only merit was that it was pleasantly situated in pure air, uncontaminated by smoke. I afterwards proved that it was capable of growing good crops of flowers and vegetables, and the salubrity of the situation was shown by the success I subsequently had with such susceptible plants to the smoke of towns as the old China Rose. On my first gaze I did not think it an ideal spot for a young would-be gardener to make his first attempt at cultivation.

My course of reading for a year or more in the *Cottage Gardener* and the "Dictionary" fortunately led me to think that deep trenching was the best thing to be done, and this was my first job in practical gardening. The soil proved deep enough to suggest this, rather than bastard trenching, as the more advisable operation. As the work progressed plenty of well decomposed stable manure was intermingled with the soil. My next step was to lay out the part nearest the house into a small geometrical flower garden, based on one of the designs in my beloved *Cottage Gardener*. These small beds I filled with herbaceous plants and the seeds of a quantity of the best annuals, selected from an excellent list furnished me by Mr. Miller, whose directions as to sowing and cultivation I most carefully followed. The remainder of the plot was devoted to vegetables and a few fruit trees. My success with this, my maiden attempt, was sufficiently great to encourage me to more ambitious efforts later on. It is needless to say I made a few mistakes, but even they proved excellent helps in the way of training.

Such was the commencement of my career as an amateur gardener; and looking back to that time I feel that I owed whatever success I achieved to the wise teaching of the *Cottage Gardener*, and can never be grateful enough that I made acquaintance with it so early in my career. From that day to this, as the *Cottage Gardener* or the *Journal of Horticulture*, it has always had a first place in my regard, and always will have, I feel sure. Should the worthy Editor encourage me with his approval of this communication I may at some future time attempt a few more of my reminiscences, and give more proofs of my indebtedness to "our Journal."—AMATEUR.

[We shall welcome further reminiscences from an ardent lover of gardening who has made great progress in the world, and induced many other amateurs by his teaching to learn to love and labour in the pursuit that has added so much to the happiness of his life.]

THE AURICULA—A HINT.

WHATEVER the future of the Auricula in Scotland, may be, its fortunes are at present at a low ebb. I speak of what are called stage varieties. Of my acquaintance, eight growers of the flower have died within fifteen years. Of two large collections the remnants still exist, I believe, in their owners' hands, and now I know of only four who make a speciality of the Auricula, one of these being an enthusiast, and the only recruit to the dwindling ranks. It is so far satisfactory that the flower is so much esteemed and well cared for in the south.

To the inexperienced, a repeated word of timely advice may be useful. At this season many a plant may be lost or saved. I have just been over my stock, giving each a little fresh surface soil. This, besides improving their appearance, encourages the emission of roots at the neck. But in a few cases I turned out the plants altogether and repotted. Growth had generally well begun, but these were laggards, and in one or two there was slight rotting of the stem and fibres. Where this is the case, and the inward turn of the edge of the leaf is an indication of something wrong, scrape the affected part quite clean, rub with powdered charcoal, repot, and a plant is saved that would otherwise probably dwindle and go off. If the rot be slight and near the surface, repotting may not be necessary. I know that beginners hesitate to turn out their plants. I do so at any season, and I have frequently exhibited successfully in May Auriculas repotted in March. In fact the Auricula rather likes to be knocked about in this way.

Severe weather at this time makes protection advisable, not that the plant itself would suffer, but the truss, in some cases already well above the foliage, would be spoiled by the frost.—A NORTHERN AMATEUR.

TRANBY CROFT.

BEING in Hesse recently I made a point of having a look round the gardens of Tranby Croft. I am not now going to attempt a full description of them. My notes were brief, time being an evening. Besides, this is not the time of year to do full justice to the several branches of gardening so well carried out by Mr. Leadbetter. In the fruit houses I noticed the earliest house of Vines swelling off a nice crop of bunches after thinning. Later Vines were breaking very well, with a promise of abundance of Grapes later on. Peaches and Nectarines were swelling freely in the early house, and the trees betokened their ability to carry a full crop of fine fruit to maturity.

In the general plant houses there was a fine display of bulbous plants of sorts—viz., Amaryllis in variety, Hyacinths and Tulips, Lachenalia Nelsoni, Begonia Gloire de Lorraine, Cyclamens, and to my great surprise some very nice heads of Poinsettias. The plants were in only 3 and 4-inch pots, and yet had heads fully 6 to 8 inches in diameter. I was assured they had done duty on the dinner table and other forms of

point north and south. It is about 75 feet in length by 18 in width. The pitch of the roof is somewhat flat, say at an angle of about 30°. As will be known to many of your readers the temperature in houses of this form is not so liable to sudden fluctuations as when the roof is of a steeper pitch. The lights on each side are about 3 feet high, and so hung that an abundance of ventilation can be given when required. Mr. Leadbetter tells me that free ventilation is one of the main necessities of successful Carnation culture indoors. Of course in the bitter weather like we are having at the time of writing care is required. For a week we have had keen north and north-east winds, with from 10° to 14° of frost every night. At no time must a stuffy damp atmosphere be allowed, or the plants are certain to suffer thereby.

There are side stages all around the house with a path and a central stage, as is usual with the general run of plant houses of the width given. These stages are covered with small, clean, sea gravel. The centre division is filled mostly with varieties of Tree Carnations. Flowers have to be supplied all the year round. Some fine plants of Winter Cheer full of flowers were very prominent. Uriah Pike promised well shortly; I

FIG. 62.—TRANBY CROFT.

house decoration on several occasions, and yet were quite fresh when I saw them. Mr. Leadbetter should give your readers his method of producing them at this time of year. In a north house were some very fine potfuls of *Disa grandiflora*, which promised to give a fine display later on. Amongst forcing shrubs were a good lot of *Spiraea confusa*. It was new to me in this form, but I am disposed to think it has a future before it for forcing. I am not sure as to its lasting qualities when used for cutting, but can answer for its adaptability for this purpose.

The night previous to my visit to Tranby there was a fairly large meeting of members of the Hesse Horticultural Mutual Improvement Society. This society offers small prizes during its winter session to various objects in connection with gardening. Many of these competitions are confined to under gardeners. The night in question the competition was for the best arranged vase of cut flowers for a drawing room table. One of the under gardeners from Tranby, viz., Mr. Donoghue, was rightly adjudged the winner. Cut sprays of *Spiraea confusa* along with a few flowers of single *Narcissi* were with foliage the occupants of his vase. However, I must not wander away from what mainly took me to Tranby. It was to see the Carnation houses.

I had heard from gardening friends who had recently seen them that they were very good, both the structures and their occupants. The house the plants are growing in is a span-roof in three divisions. Its ends

have not seen such healthy, free-growing plants of this variety as were here. The two end compartments were filled with varieties of *Malmaison* Carnation. They certainly were fine, well-grown plants. Mr. Leadbetter does not grow them on after the second year from the layers, unless it chances to be a plant or two of some new variety. Last year's layers were on the side stages, mostly in 5 and 6-inch pots. The previous year's layers were on the centre stages in 8 and 9-inch pots. These latter are allowed to carry one flower only to a shoot. I could see that many of them would thus produce from fifteen to twenty flowers.

The potting material is mainly Banstead loam, with clean sand, and in some cases a little fine peat or well decayed leaf soil is added. Good drainage is an absolute necessity. Some broken oystershells may be used over the crocks. Firm potting should be attended to, as if potted at all loosely the roots are sure to suffer in winter from over-moisture. When the flowers are opening occasional waterings of weak clear soot water are given. Great care should be used in giving artificial manure. The flowers may be increased in size by it, but there is risk in the constitution of the plants being injured, which tells later on when either repotted for the second year's blooming or used for increasing the young stock of plants raised annually about August.

Mr. Leadbetter affirms that if a suitable structure is at hand and attention paid to airing, watering, firm potting, also good general attention

is given, there is no difficulty in the successful cultivation of these very useful and beautiful all-the-year-round flowering plants, at any rate the results of his work and directions are self-evident.

I append names of the leading varieties grown at Tranby: Winter Cheer, Uriah Pike, Duke of Fife, Mrs. Leopold Rothschild, Princess of Wales, Churchwarden, Lady Grimston, Mrs. E. Hambro, Trumpeter, Calypso, Prime Minister, and Princess May, which is very highly spoken of by experts in this class of plant.—H. J. C., *Grimston*.

[Though our contributor shrinks from making reference to the grounds of Tranby Croft, we may say of them, after a visit paid during the early summer of last year, that they are amongst the most charming that it has been our pleasure to see. As a suburban home Tranby Croft is ideally beautiful, and the interest of Mr. and Mrs. Arthur Wilson is in favour of the embellishment of its many beauties rather than the reverse. The variety and excellence of the Conifer avenue would be difficult to excel in the county of Yorkshire. The trees are in splendid form, though rather too thick to allow of their individual proportions being appreciated to the full. In the pleasure grounds and gardens

them, as he was a frequent visitor at The Grange Gardens, Wallington, when I was local secretary for that district, and he scarcely ever left without contributing at least a shilling, sometimes more, to the money box there. In that way he paid more than the usual 5s. annual subscription, but owing to the manner it was given it was credited to me, and forms part of the £80 that is placed to my name in the list, which is sufficient to pay allowances to six orphans for one year. As it happened, his children had left the country before the date of the election, and were thus disqualified from receiving any benefit from the Fund.

It would be a great help to the Fund if every gardener would adopt the practice of having a money box and drop in a weekly coin himself, and give other people an opportunity of doing likewise. Mr. B. Wynne, the Secretary, would be delighted to receive the contents of the boxes, and the total amount from these should be sufficient to insure the election of several poor children.—G. W. CUMMINS, *Balmedie, Aberdeen*.

YOUR correspondent "A. D." (page 153) is anxious to know why there is so much indifference shown on the part of gardeners towards this Fund

FIG. 63.—IN THE GARDENS OF TRANBY CROFT.

surrounding the mansion endeavour has been made to form fresh features and to present additional charms to the visitor, and success has crowned the efforts made. The winding paths, the nooks and corners, convey the impression that the estate is very extensive, whereas it is compact, and the best use has been made of the space to be dealt with. The skilful hand of Mr. Leadbetter is seen out as well as indoors, and in every department of a busy establishment there is a tidy cleanliness that is most pleasant to observe. It is not now possible for a complete description of the estate to be given, so two photographic views are provided. The former affords a peep into the pleasure grounds and a glance at the mansion beyond, and the latter shows the herbaceous borders in the kitchen garden. Tranby Croft is one of the estates in the north of England that are best worth a visit, and when anyone makes a tour, however brief, must be included. Our photographs were taken by Mr. W. E. Martin, *Hull*.]

ROYAL GARDENERS' ORPHAN FUND.

I MUST take exception to the statement of "H. D.," page 153, that "not one of the fathers of the nineteen children nominated for election this year had been a subscriber to this Charity." True, their names are not in the list of subscribers, but I was personally acquainted with one of

I will not attempt to answer this question, and not being a subscriber myself I know nothing of the inner working of the Fund. One cannot, however, shut one's eyes to the fact that there is a great amount of dissatisfaction expressed amongst subscribing gardeners in the provinces as to the salary given to the Secretary, which is £100 per year. This is more than nine-tenths of the gardeners in the country receive. It thus takes the subscriptions of 400 gardeners to pay the Secretary his salary before there is anything for the orphans. I have heard subscribers discuss this subject in various parts of the country, and in no instance have I heard one of them uphold the management. One and all expressed themselves as opposed to so much being paid in salary. There are probably many subscribing gardeners in the country who would do the work equally well for half that amount, which would benefit the poor children for whom it was intended. In any case, a little light on this subject will do no harm to the society.—S., *Yorks*.

"A. D." asks why more gardeners do not subscribe to the funds of this Charity. I will give him one reason—viz., the appointment of a Secretary at a salary of £100 a year. Country gardeners fail to see why their money should be spent in this lavish manner. One would have thought half that sum was sufficient remuneration for secretarial duties. This is not merely the opinion of myself but that of hundreds of gardeners throughout the country.—A COUNTRY GARDENER.

EARLY SPRING AROUND JERUSALEM.

THE writer recalls many features of interest, such as an ardent lover of Nature might revel in, during a sojourn in the unique configuration of this for all time wonder-enthralling country. At the first blush I must confess the soil seemed as if its powers of fertility had been utterly extracted, and only a grey rocky and barren crust survived, not much else than the sombre but useful Olive being in evidence, and many of these gnarled and stunted to a degree.

Standing as it does some 2500 feet above the level of the Mediterranean, Jerusalem and the peaky mountainous tableland around has, as may be surmised, an atmosphere keen and extremely invigorating early in the year. I recollect if I made a start betimes in the morning, the roads were hard and the ground white with hoar frost. You may, too, experience a cutting cold wind. Nevertheless the sun is very powerful, and by midday of such great heat as to account for the early growths in flowers that one comes across.

Even on these elevated heights, and no later than mid-January, I was delighted with the lovely red Anemones and Orchids amongst other flowers which I saw in my saunterings round about Bethlehem, Solomon's Pool, and Hebron. The latter is, I think, considerably lower in altitude than Jerusalem, and is famous, besides the mosque where the patriarchs are buried, for the time-honoured Abraham's Oak. This said tree is of gigantic girth and proportions, and evidently sufficiently venerable looking to sustain its legendary character. I bore away with me as a trophy one of the huge acorns with which the ground was strewn. A precocious kind of Gentian revealed itself to me in the Valley of Jehosaphat between Jerusalem and the Mount of Olives. On the very summit of the latter, after enjoying the hospitality of a resident there, I gazed my fill from the house top upon the most sublime and marvellous *coup d'œil* which I have ever experienced, the most striking features being the far away Dead Sea, with the blue mountains of Moab in the extreme background bathed in the glories of the setting sun. Had the "latter" rains not failed the season I was in Palestine, doubtless many other flowers would already have burst into bloom.

A fairer and more likely field at this early period affords itself down in the plains of the Jordan. Quite a carpet of the red Anemone we galloped over in our scamper on our game little Arabs across these plains from Jericho to the Dead Sea. Were such ever again taken in hand and cultivated by irrigation, what a rich and fertile harvest would result. The Jericho Oranges are the finest in the world, eclipsing those even of Jaffa, but unfortunately do not stand exportation. The contrast in the climate from Jerusalem owing to its position under the mountains, and the remarkable descent to 2500 feet below the level of the Mediterranean, causes Jericho to be a place of very great heat and the lowest city in the world.

Having trusted myself to the rather uncanny looking waters of the Jordan by way of an early morning bathe, in company with several others we rowed down the river into the Dead Sea, and after another bathe, in which I tried the possibility of sinking without any success, my dragoman and I plunged into the wilds of the Dead Sea Mountains, with the view of reaching the lonely monastery of Mar Saba before sunset. A weirder spot it would be hard to find. Built on the very edge of a precipitous gorge, the monks, to the bearer of a letter of introduction from the Armenian Patriarch, receive a traveller, and give him a bare sustenance of bread and water, and a lodgment for the night. In my own case we were not destined to reach there as soon as hoped, for after going up and down the most pathless and impossible-looking mountains, my dragoman (a Syrian Jew) frankly acknowledged he had lost us. I intimated to him that his backsheesh would be lacking, and broke my umbrella over his back, but to no avail; and being almost dark (there is scarcely any twilight) we accepted *faute de mieux* the hospitality of a Bedouin Arab encampment, and reposed our limbs in the tent of a patriarchal Sheik after a sumptuous repast, together with two pure white camels, a lot of black goats, and innumerable smaller companions of a more troublesome nature.

Here towards dawn the jackals and hyenas helped to wake us for an early start across those wild and desolate regions in the howling wilderness of Judæa, towards our belated goal. Very fresh and beautiful, however, was the sunrise, and the dew sparkled like crystals on some fragrant blue and yellow cup-shaped flowers, which were just appearing in the more sheltered nooks of this vast elevated tableland of mountains. Our Sheik guided us to Mar Saba, and there left us, rejoicing in a liberal amount of backsheesh. Truly these sons of the Desert are a fine, enduring, and heroic race, of splendid physique, and possessing a most dignified and patriarchal mien.

I realised a peculiarly subtle charm in this historic part of Palestine, and left the country by the difficult and dangerous Port of Jaffa with much regret, and a keen desire to revisit the scenes of such abiding interest.—J. A. CARNEGIE-CHEALES.

THE OSAGE ORANGE.

I HAVE read the interesting account of the Osage Orange in your issue of 15th December last, page 453. Perhaps you would kindly give me some further information on the subject. I may say that I know little of gardening or horticulture. In the year 1880 I brought from St. Louis a strange fruit that was new to me, called the Osage Orange. It had a delicious scent, but was apparently quite uneatable. I dried the seeds and planted them, and in a few years we had at Chislehurst, in a sheltered but not protected garden, a fine impenetrable hedge, growing 6 or 7 feet in the year, and which had to be severely cut back to keep it within bounds. I have just obtained from America some cuttings to plant in Worcestershire, as we found that the plants we endeavoured to take from Chislehurst would not grow.

In January of this year we found in the markets of Algiers and Biskra a fruit which we fancied must be an Osage Orange, though the rind of the fruit was rather smoother than that of the one we brought from America.

The Osage Orange makes such a magnificent hedge, with its long stiff thorns, and seems to be so hardy, that I should be glad to know how to cultivate it to advantage. I may mention that our hedge at Chislehurst never had flowers or fruits.—RICHARD B. MARTIN.

[It would be interesting to know if the Osage Orange hedge at Chislehurst passed without serious injury through the memorable frost of February, 1895. We do not know of any better account of the shrub or tree than that of Mr. Jefferies above cited. It has been long known, but not, so far as we are aware, grown to any noticeable extent in England.

Some years ago a proposal, if not an attempt, seems to have been made to cultivate the tree for its fruit in this country, a rather curious notion, as it is not conceivable that anyone would eat the fruits if they were produced, for, though they are not unpleasantly perfumed, there is no evidence that the native North American Indians ate them. They smeared their spears with the juice before going to war, and made bows, if not arrows, of the wood for shooting their enemies, and hence the tree is popularly called "bow-wood."

As to "cultivation," this, for the purpose of fruit production would, we presume, be much the same as that which is appropriate to the Fig, which belongs to the same natural order. Whether grown against walls, or as open standards in favourable positions in the south of England, Fig trees do not bear till they arrive at maturity, and produce firm, short-jointed wood, which ripens to the tips. They would never do so if cut closely back yearly to keep them in hedge form, as then they would produce gross and essentially fruitless growths after the manner of the "Orange" hedge of Chislehurst.

The Osage Orange (*Maclura* or *Toxilon*) however, does not belong to the Orange (*Citrus*), but, like the Fig and the Mulberry, to the Nettle family, and the trees when mature are said to attain a height of from 20 to 60 feet in some parts of America. Moreover, as Mr. Jefferies remarked, *Maclura aurantiaca* is dioecious, the staminate (male or pollen bearing flowers), and the pistillate (female or fruit producing forms) being produced on separate trees, so that both kinds are necessary for fruiting purposes, and then specially favourable conditions and many years of waiting for a crop. The tree from which the specimen figured in December was taken is said by Mr. Jefferies to have been growing for many years against a wall with a southerly aspect.

Reverting to the proposed Worcestershire "hedge." The failure of the plants removed from Chislehurst probably resulted from their either being too large for successful transplantation, or to their not having been cut down nearly to the ground after planting. If they were not so cut down, and more are obtainable, let the plan be tried. We fear there is no certainty that the cuttings procured from America will grow. Cuttings of the roots are said to be more likely to do so than cuttings of the shoots, and plants are also increased by layering. If more seeds can be procured from America the Chislehurst experiment might be repeated, with the expectation that it would answer in Worcestershire.

We shall be glad to have particulars of further attempts to establish a hedge and the results of them. There are plenty of Osage Orange hedges in America, and there may be some in England, though we do not happen to have seen them. The Chislehurst example certainly showed abundant freedom of growth, but we should like to know what effect the arctic frost of 1895 had on the quickly formed and "impenetrable hedge."]

BROCCOLI SPRING WHITE.—For early use this is a particularly reliable and useful variety, and is one that has been proved, not once or twice, but over a series of years. Broccoli is neither abundant, nor in my case of normal size and strength. Small heads are nevertheless of much value now, and furnish an agreeable change to Brussels Sprouts, forced Beans, Asparagus, and other green and root crops. It is a variety that those who may have had a difficulty in getting an early spring supply in past seasons should make a point of securing, to sow during the next fortnight.—W. S.

COMMISSIONS.

BUT for the revelations—of whose truth or otherwise one does not venture to express an opinion—in a certain notorious case, it is doubtful if the question of commissions would have engaged the attention of the Legislature. Now, however, that the Lord Chief Justice of England has taken up the matter, and has prepared a Bill to deal with it, it is probable that some attempt will be made to strike a blow at what are called illicit commissions. That the attempt has not been made too soon is evident from the statements in the Press and from what has come to one's notice. How far the system can be coped with is doubtful, but one cannot but hope that some good may result. The system rules everywhere, and many of its forms are indefensible. We cannot, for instance, defend a system which enables, say a solicitor advising a client over an investment, pocketing a commission from the transaction in addition to his fee for advice and ordinary legal charges. The commission system is hydra-headed, and not at all easy of solution. It is, however, of its application to gardeners and gardening that one would like to speak.

Those best acquainted know that the commission system as it affects employers and their gardeners is comparatively innocent. It is a matter of notoriety that a small commission on orders is generally given by nurserymen to gardeners. This is, one knows, often with the cognisance of employers, who look upon the 5 per cent., or sometimes more, as a small addition to the wages—none too large—of their employés. Some nurserymen set themselves against this practice, and apparently carry on flourishing businesses without its aid. Yet they seem to be the exception rather than the rule; but there is no doubt that nurserymen generally would be glad to see the commission system abolished.

Looking at the matter from the point of view of the employer, who is unaware of it, or who knows it is practised yet is powerless to prevent it, there is little doubt that its prevention would be a gain. All men are not patterns of virtue and honesty. Gardeners, exemplary as they are as a class, have black sheep among them. Among such even a small commission may lead to carelessness in many forms—to extravagant orders for seeds, plants, or sundries, and to general wastefulness in their use. It can hardly be doubted either that the abolition of commissions would in the long run tend to the advantage of the purchaser.

To the gardener, however, who, in accordance with long-established custom, has had his salary supplemented from this source the change would be unprofitable, and in many cases unpleasant. It can hardly be denied that gardeners as a body are not over-well paid, when one takes into consideration their experience, skill, and responsibility. It would thus seem that in defence of the retention of the system could be urged the plea that as far as regards gardeners it is recognised by most people, and is a legitimate addition to their earnings. Yet how small it is in the average garden, and how little an addition to the salary would it prove when put down in £ s. d. It would be better for all if the employer in making his agreement would give a little higher wage, and make the bargain that no commissions were to be taken.

There is in existence, one has had too good reason to believe, from what has occasionally been seen from the columns of the *Journal*, a more demoralising thing still. This has been the giving of testimonials to new seeds or plants in return for a consideration. One recollects a case in which identically worded notes recommending a new speciality were received at the office. This was properly condemned by the Editor, no names, of course, being given. Such practices bring undeserved discredit upon the honest opinions of good men and true in the gardening ranks and among the writers to the horticultural press. Because some are dishonourable those who would scorn to give anything but an unbiased opinion have suspicion cast upon their honest recommendations or criticisms.

The writer has had not a little experience in writing for the *Journal*, and it is due to the great body of those with whose products he has had to deal to say that he has not been approached corruptly to speak favourably of what was offered for sale. Yet offers have been made which would have been to his advantage, and would have tied his freedom to write without regard to personal considerations. He may thus be excused for writing at length upon a question now before the minds of many, and of much importance to gardeners and to the horticultural trade.—PENMAN.

P.S.—Since writing the foregoing I have had an opportunity of perusing the report from the Special Committee of the London Chamber of Commerce on this question. If anyone thinks my studiously carefully written letter goes too far, they will discover ample justification for it in the report. I believe the abolition of commissions would eventually be to the advantage of all concerned—employer, gardener, and nurseryman.—P.

THE TEMPLE FLOWER SHOW.

I NOTICE with regret that the Council of the Royal Horticultural Society have resolved to eliminate from the next great flower show in the Temple Gardens all floral decorations, whether vases, stands, bouquets, sprays, or others. I think that is a mistaken interdiction, because it helps to reduce the show more than it previously was to one dead level of monotony in the material and in the arrangements. Admittedly some of the floral decorations did show the art of preparing them sometimes rather run mad, a few simple regulations might have soon brought the exhibitors into a sane frame of mind. But without doubt exhibits of this nature are remarkably popular and attractive, especially with ladies, and the fair sex invariably comprises the larger half of the visitors.

The art of floral decoration is one of great importance in connection with horticulture, because it presents ways and uses for flowers commonly both beautiful and domestic, which is not only to be greatly commended,

but gives wonderful encouragement to production. There is not a flower show in the provinces, or indeed anywhere else, whereat floral decorations are not made prominent features. There are usually many exhibits at the Temple Show that could bear great reduction with benefit, and thus make ample room for the decorators' and bouquetists' displays. It is true the Council have this year very rigidly limited spaces for certain things, and some good should result, for the great evil of the show hitherto has been too much liberty to make big exhibits, rather than calling for the very best products only.

There is one regulation which a little bothers me to comprehend, and that is the requirement that the backs of rockeries, whilst not over 6½ feet in height from the ground level, must, if on the central stage, have the backs of such erections neatly covered with green baize on both sides. Whenever did a back have more than one side? Evidently something is meant that is not conveyed. Perhaps it means that if there are two backs both must be covered, but then the front side is invariably covered with the rockery and plants upon it. Really such erections should not be permitted at all on the centre stage. The side tables, or on the ground, are the proper places for them. I regret to see so much as 400 feet of ground space allotted to such monotonous plants as *Caladiums* in single groups. Were they used to furnish a carpet to pleasing tall or standard plants each would enhance the beauty of the other.—A. D.

NORTHERN SPY APPLE FOR STOCKS.

THE MARIANNA STOCK FOR STONE FRUITS.

I HAVE been much interested by the controversy that has lately been carried on in your *Journal* on the subject of fruit culture, more especially that of Apples cultivated on the dwarfing system, of which I greatly approve. I have been a grower of fruit, and interested in fruit culture all my life, and in this country for over forty years, so that perhaps I have some little claim to make the following statements.

Owing to the mildness of this climate, one of the worst, if not the worst, enemies to the cultivation of the Apple is the woolly aphis, which attacks both roots and branches to such an extent that until the resistant stocks—viz. the Winter Majetin and Northern Spy—were introduced only a few varieties of Apples could be grown, and those were generally only short-lived. Of the two stocks mentioned, the Spy is decidedly the better—in fact, I believe it is the best stock in the world, apart from its resistant qualities.

I have grown over 500 varieties on it, and from the strong-growing Blenheim Pippin to the weakly Siberian Crab have found the union perfect—no throttling between stock and graft, but a perfect smooth union, which cannot be said of any of the Paradise stocks used. Mr. Sharp, owner of a large experimental orchard at Waikomete, near Auckland, tells me he has fruited upwards of 1500 varieties of Apples grown on the Spy stock, and has never met with any variety in which the union was not perfect. I have found, too, that they bear heavily, and produce extra fine fruit, also by judicious pruning of top and roots dwarf trees can be obtained. In one of our Government Experimental orchards there are numbers of trees not more than 3 feet high bearing Apples, which for size and general appearance cannot be surpassed by those produced in any other part of the world. I feel certain that if some of the English nurserymen would experiment with the Northern Spy as a stock it would prove a success. It is easily grown, either from layers, root grafting, or from root cuttings.

I would like also to recommend a stock we have been using lately for stone fruits, called the Marianna. I believe it came originally from California. Plums, Peaches, and Apricots thrive on it, growing well and fruiting freely. It does not sucker, and grows here as freely from cuttings as a Willow.

I may add in conclusion that few people take more interest in horticulture than myself, and if I can interest others I take a pleasure in so doing.—W. J. PALMER, *Government Pomologist, North Island, New Zealand*

[Though we have seen trees of Northern Spy Apple entirely free from the woolly aphis, or American blight, while the branches of other varieties of Apple trees adjoining were infested, it still appears singular that the roots of the "Spy" stock should render the branches of the Margil, or other varieties of Apples that might be established on the "Spy" proof against the attacks of the enemy. The characteristic essences of Apples—at least that prevail in the fruit—seem to be the same on whatever stock the trees are grown, as is apparent in the case of several varieties being established on the same stock by grafting. This goes to show that the leaves are the agents in providing those essences that give to varieties of fruits their particular flavour, and not the roots, which gather the crude materials that the stems convey to the leaves for elaboration and assimilation. We could understand a branch of the Northern Spy growing, as the result of grafting, on a tree of the Margil, or any other Apple, being free from the aphis, while the other branches of the tree were infested, but cannot so clearly see how and in what way the roots of a stock should have the potent influence suggested. We do not for a moment question the accuracy of Mr. Palmer's statement. We have heard of the same freedom from the aphis of trees on the "Spy" before, and shall be obliged if our Antipodean correspondent can explain the reason of the immunity in question—a matter which can scarcely have escaped the attention of Government scientists. We have no doubt whatever that Apple trees can be made abundantly productive on the "Spy" stock, and it seems to be worth trying in this country. Of the "Marianna" stock for stone fruits we have no knowledge, at least under that name. We are obliged to Mr. Palmer for his interesting communication.]

ROYAL HORTICULTURAL SOCIETY.

DRILL HALL.—MARCH 28TH.

THE meeting was very much smaller than usual at this season, the Orchids were almost conspicuous by their absence, and the exhibits of fruit and vegetables were practically nil, while the chief of the floral displays consisted of spring flowers, Roses, Clivias, and Ferns.

FRUIT AND VEGETABLE COMMITTEE.—Present: Philip Crowley, Esq. (in the chair); with Messrs. W. Wilks, J. Cheal, Jas. H. Veitch, A. F. Barron, A. H. Pearson, A. Dean, S. Mortimer, W. Bates, G. Wythes, H. Balderson, F. Q. Lane, J. Smith, J. Willard, and R. Fife. The duties of this Committee were very light.

Mr. A. J. Thomas, Rodmersham, exhibited a dish of seedling Apple Diamond Jubilee, which the Committee desire to see again. Messrs. Richard Hartland & Son, Cork, staged a dish of Drought's Favourite Apple. The R.H.S. Gardens contributed a collection of twenty-eight varieties of Onions to illustrate their keeping properties. The best were Bedfordshire Champion, Danver's Yellow, Sutton's Al, Magnum Bonum, and Sutton's Eclipse, while the whole were in a good state of preservation. Mr. R. C. Notcutt, Woodbridge, Suffolk, sent a dish of Pear Winter Orange, a variety well known in the eastern counties. Messrs. Walker Bros., Basinghall Street, E.C., sent a bunch of Grapes from the Cape; the flavour was good for the season, but the cork dust should have been removed before placing the fruit on the table.

FLORAL COMMITTEE.—W. Marshall, Esq. (in the chair). Present: Messrs. O. Thomas, H. B. May, C. Jefferies, R. Dean, J. H. Fitt, W. Howe, C. J. Salter, G. Gordon, E. H. Jenkins, J. D. Pawle, C. R. Fielder, C. E. Shea, J. W. Barr, H. J. Cuthbert, E. Beckett, E. T. Cook, H. J. Jones, H. Turner, R. W. Kerr, G. Paul, J. Jennings, and H. Selfe-Leonard.

Messrs. W. Paul & Son Waltham Cross, staged a good display of flowering shrubs; the Carnation-flowered Peach with its rosy flowers, the Camellia-flowered form of a more delicate shade, the double Almond, *Pyrus floribunda* Scheideckeri, the double *Prunus sinensis* flore pleno, double French Cherry, *Cytisus scoparius* præcox, *Choisya ternata* beautifully flowered, and *Magnolia stellata*, a beautiful form, contributed to the collection, while the whole was edged with variegated Ivies, *Deutzia parviflora*, and *Osmanthus ilicifolius* variegatus (silver Flora medal). Messrs. J. Veitch & Sons, Chelsea, staged a group of *Cerasus pseudo-cerasus* in very fine form, with a good basket of *Chionanthus virginicus*, *Azalea mollis* albicans with creamy flowers, and *Loropetalum chinense*; also a small group of *Hippeastrums*, one plant bearing seven spikes receiving a cultural commendation. Messrs. J. Hill & Son, Lower Edmonton, contributed one of their well known exhibits of Ferns, comprising specimens of *Cyathea insignis*, *Asplenium caudatum*, *Gymnogramma peruviana* and *chrysophylla*, *Pteris tremula* Smithiana, *Asplenium nidus*, and *Pteris Wimsetti*, excellent plants of *Asplenium Hilli*, and baskets of small *Pteris palmata*, *P. cretica nobilis*, *Adiantum cuneatum* Legrandi, *Nephrodium lepidum*, and *Nothochlæna nivea*.

Messrs. R. & G. Cuthbert, Southgate, staged a collection of *Azalea mollis*. The plants were masses of bloom in a wide range of delicate colours, set up in a bed of Ferns, making a bright attractive exhibit (silver Banksian medal). Mr. G. Mount, Canterbury, again staged a beautiful collection of Roses in boxes, also in vases, with about 18 inches of growth. The most noteworthy were Bridesmaid, Captain Hayward, Madame Montet, La France, Catherine Mermet, Madame Gabriel Luizet, Mrs. John Laing, and Niphotos (silver Flora medal). Messrs. R. Wallace and Co., Colchester, exhibited a small but interesting display of spring flowers, chiefly *Erythroniums*, including *E. revolutum*, Hartwegi, and Johnstoni, with a variety of the Grape Hyacinth, and *Iris reticulata* and *I. caucasica*. Messrs. B. S. Williams & Son, Upper Holloway, exhibited a collection of Clivias. The plants were well grown, and the flowers bright and fresh. The best forms were Marie Reimers, aurantiaca, Prince of Orange, Scarlet Gem, and Van Houttei. Messrs. W. Balchin and Sons, Hassock's Nurseries, Sussex, contributed one of the most interesting displays in the hall in a group of *Boronias*, grown and flowered in splendid form, reminding one of the old days when these plants were popular. *B. heterophylla* was really wonderful, while *B. serrulata* and the curious megastigma were also remarkable alike for their growth and perfume (silver Flora medal).

Mr. H. B. May, Upper Edmonton, staged a fine collection of *Blechnums* and *Lomarias* in forty species and varieties. The chief were—*Blechnum corcovadense* crispum; *Lomaria gibba* robusta, *L. ciliata* Mayi, *L. gibba*, and *L. ciliata* undulata (silver-gilt Banksian medal). Messrs. Barr and Sons, Covent Garden, staged an extensive display of *Narcissi*, comprising the beautiful Queen of Spain, bicolor Horsefieldi, Barri conspiens, tortuosus, Henry Irving, b. Victoria, grand; Emperor, Madame de Graaff, cernuus, Golden Spur, albicans, and many others too numerous to note (silver Flora medal). Mr. P. Purnell, Woodlands, Streatham Hill, exhibited a collection of *Primulas* and alpine plants, forming a very interesting feature. The blue *Primroses*, *Sempervivums*, *Saxifragas*, *Iris persica*, and *Gentiana acaulis* were very attractive to all lovers of this interesting class of plants. Mr. J. Russell, Richmond, exhibited a group of *Dracæna lentiginosa*, a capital decorative plant, with the foliage of *D. indivisa*, but copper-coloured, also a basket of *Viburnum macrocephalum*, a gigantic Gueldres Rose, closely resembling a *Hydrangea*.

Messrs. F. Sander & Co., St. Albans, contributed specimen plants of *Acalyphas* Sanderi and *Godseffiana*, also *Sanderiana*. The *Acalyphas* were very bright at this season. Mr. W. Rumsey, Waltham Cross, staged an extensive display of Roses, comprising five good boxes and numerous sprays. The best were Maréchal Niel, Magna Charta, Général

Jacqueminot, Mrs. Rumsey, The Queen, Gloire de Margottin, Susanne Marie Rhodocanachi, and Souvenir d'un Ami (silver Banksian medal). Messrs. T. S. Ware, Ltd., Tottenham, exhibited a group of spring flowers, consisting chiefly of *Narcissi*, *Chionodoxa sardensis*, *Muscari*, the curious *Fritillarias pudica* and *aurea*, *Gaultheria procumbens*, *Hepaticas*, and *Primulas*. Mr. F. Cant, Colchester, staged a box of Roses, and a few sprays of W. A. Richardson of the correct colour. The best specimen blooms were Niphotos, Madame Hoste, Cleopatra, The Bride, Catherine Mermet, and Maréchal Niel; also plants of *Polyantha* Rose Thalia, a white form, which appears to be very free flowering.

ORCHID COMMITTEE.—Present: Harry J. Veitch, Esq. (in the chair); with Messrs. J. O'Brien, R. B. White, H. Ballantine, N. C. Cookson, A. Outram, A. H. Smee, J. T. Gabriel, H. J. Chapman, W. H. Young, F. J. Thorne, E. Hill, W. H. White, J. Jaques, H. T. Pitt, W. H. Protheroe, J. Colman, W. Thompson, J. G. Fowler, F. Mason, T. B. Haywood, and S. Courtauld.

Sir Trevor Lawrence, Banford, Dorking, staged a very choice group of Orchids, consisting of *Odontoglossum Halli*, *O. prionopetalum*, *O. triumphans*, and *crispum*, with a well flowered specimen of *Cattleya Lawrenceana*. The *Cypripediums* *Rothschildianum* and *C. Stonei grande* were very attractive, as were good specimens of *Dendrobium Wiganæ* and *D. Euterpe*, a cross between *nobile* and *Wardianum* (silver Banksian medal). Messrs. Hugh Low & Co., Bush Hill Park, Enfield, staged an interesting group of Orchids, comprising excellent specimens of *Cattleya Trianae* Amesiana, *C. T. enfieldense*, a very beautiful pale form, *Lycaste Skinneri* Imperator, *Dendrobium Vennii*, a deep form of *nobile*, and a good variety of *Odontoglossum*. Mr. Pitt, Stamford Hill, staged a very interesting collection. The *Odontoglossums* were excellent, as were also the *Miltonias* and *Dendrobiums* (bronze Banksian medal).

Messrs. Linden, Brussels, sent a good form of *Odontoglossum Halli* and a *Cypripedium Pauli* superbum. Mr. N. C. Cookson, Oakwood, Wylam, exhibited some good forms of *Dendrobium nobile*. Mr. de B. Crawshaw, Sevenoaks, staged a grand variety of *Odontoglossum crispum* with very broad flowers, also a well flowered plant of *O. Andersonianum*. Mr. W. Thompson, Walton Grange, exhibited a plant of *Odontoglossum Halli* leucoglossum nigrum, which attracted a lot of attention; also a good *O. Wilckeanum* Primate, a yellow form with broad blotches of brown throughout the flower. Mr. W. C. Walker, Winchmore Hill, exhibited a well-flowered plant of *Eriopsis Ruidobulbon*.

CERTIFICATES AND AWARDS OF MERIT.

Azalea hybrida (R. & G. Cuthbert).—A cross between *A. mollis* and *sinensis*. A rosy orange form with the upper segment spotted with a deeper shade (award of merit).

Cattleya Trianae Amesiana (Hugh Low & Co.).—A good variety. Sepals and petals white, lip white with orange at the base, the outer portion pale mauve (award of merit).

Dendrobium emalculatum (J. Sparkes).—A small, but pretty flower, having a violet lip; the sepals and petals white at the base, with yellow tips (botanical certificate).

Erica propendens.—A good *Erica* with mauve flowers, very free (first-class certificate).

Lælio-Cattleya nigra var. *Etoile d'Or* (Jules Hye).—Sepals dull yellow, petals slightly paler, throat veined with chocolate lines (first-class certificate).

Narcissus King Alfred.—A fine form with broad perianth and a bright yellow tube (award of merit).

Odontoglossum nobiliss (Jules Hye).—Sepals and petals yellow with large blotches of chocolate, lip slightly fringed, yellow at the base with paler edges (award of merit).

Pear Winter Orange (R. C. Notcutt).—A stewing Pear of considerable merit, said to be well known in the eastern counties; a short fruit with a deep brown skin, and an open eye (award of merit).

SCIENTIFIC FRUIT CULTURE.—When I asked a distinguished Welsh fruit grower, at the close of Mr. Pickering's recent lecture on the experimental work being conducted on the Woburn Fruit Farm, what he thought of it all, he said, "Well, I have come hundreds of miles to hear this lecture, and I am none the wiser." Possibly hard-headed, practical fruit growers cannot appreciate new forms of scientific teaching. Still, with every disposition to be a learner, I could not for the life of me comprehend how or in what way much of what seemed to be trivial experimentation carried on at Woburn was going to benefit fruit culture. I could but fancy that some of the grave and experienced seigneurs who sat and listened to the lecture must have wondered what they, as fruit growers, had been at all their lives that this sort of thing should be needful. I found it difficult to repress a smile, for I like to show all possible courtesy to those from whom I may differ, when I learned that it was the practice to have the sixth leaf from the point of each shoot on the young trees gathered each season and weighed, to enable a test to be obtained of the respective tree's development; also that it was the practice to have all the prunings from the trees severally weighed also, and even thought the person who had to perform such duties, and tabulate them, merited some sympathy. Really, should there be anything of a practical nature to be deduced from the Woburn experiments, it is evident that nothing useful or tangible can be so obtained until some ten or twelve years have elapsed since planting, and if the work of leaf picking and weighing has to go on all the time, as well as taking the weights of the prunings of each tree, it must be a time of trial to somebody. Let us hope that great good, not apparent now, will be the eventual outcome of what must be a tedious and time-absorbing operation.—A. D.

KEW NOTES.

THE north wing, added to the temperate house last year, is to be opened to the public at Easter. The erection of this house completes the building according to the original design, modifications only being made in such modern improvements as would insure the maximum amount of light with safety to the structure. Its dimensions are similar to those of the south wing—Mexican house, finished in 1897—i.e., length inside 112 feet, width 62 feet, height 37 feet. As in the Mexican house, everything is planted out, the beds being arranged similarly. The centre path is a continuation of that running through the entire structure, making in all a promenade 200 yards long. Although fitted with hot-water apparatus, fire heat will only be given in cases of a very severe frost.

Using this building as a cold house fills a long felt want at Kew, there being many choice flowering and ornamental foliage trees and shrubs that are not altogether hardy, but require little protection. Particularly is this the case with many of the Chinese, Japanese, Himalayan and Californian plants, and it is from these countries—more particularly the three former—that plants have been selected to furnish the structure.

The place of honour is given to Himalayan plants, and the house will in future be known as the Himalayan house. Rhododendrons naturally take the foremost place, a large number of species being represented. Of the species may be mentioned *R. arboreum*, *Falconeri*, *barbatum*, *niveum*, *argenteum*, *Nuttalli*, *Dalhousiae*, *calophyllum*, *fulgens*, *formosum*, *Edgeworthii*, *Griffithianum*, *triflorum* (fig. 64), and *ciliatum*. In addition to these there are a number of garden hybrids, such as *Kewense*, *Countess of Haddington*, *Forsterianum*, *Lady Alice Fitzwilliam*, *Gibsoni*, *Sesterianum*, and others. Several plants of *R. præcox* have been a mass of bloom during the last few weeks, showing what a little protection does, as outside every flower has been killed by frost. Other notable Himalayan plants are *Pentapterygium serpens* and *rugosum*, *Vaccinium leucobotrys*—"Bengal"—*Luculia gratissima*, *Buddleia Colvillei*, *Agapetes buxifolia*, *Elæagnus latifolius*, and *Magnolia Campbelli*. Several other genera are represented by one or more species, as *Decaisnea*, *Acer*, *Cornus*, *Pieris* and *Liliums*.

Turning to Chinese and Japanese plants the following are worthy of mention:—*Camellias* *Sasanqua*, *rosæflora*, *Thea*, *reticulata*, *hongkongensis*, and varieties of *japonica*. *Rhododendron decorum*, *lacteam*, *Delavayi*, *hybridum*, and *yunnanense* from Yunnan, and *R. serpyllifolium*, *Schlippenbachii* and *linearifolium* from Japan; *Styrax japonica*, *Stuartia pseudo-Camellia*, *Loropetalum chinense*, *Diospyros Kaki*, *Photinia japonica*, *Pæonia Moutan*, and *Nandina domestica*. In addition to these the following are represented:—*Lilium*, *Clerodendron*, *Ardisia*, *Rubus*, *Dendropanax*, *Quercus*, *Rhaphiolepis*, *Akebia*, *Rosa*, *Citrus*, *Acanthopanax*, *Magnolia*, *Ligustrum*, *Edgeworthia*, *Illicium*, *Meliosma*, *Euonymus*, *Abelia*, *Hydrangea*, and others.

Among the few plants from other countries are *Magnolia grandiflora*, *Fremontia californica*, *Carpenteria californica*, and *Tricuspidaria Hookeriana* from the New World, the extremely rare *Quercus alnifolia* from Cyprus, and some of the winter flowering *Kniphofias* from S. Africa. For clothing pillars and roof, garden *Clematis*, *Roses*, and other plants are employed.

Variation is given by two rock pools, the ends of two centre beds being utilised for the purpose. Here water and marsh plants are to be grown, while the rocks are utilised for *Saxifrages*, *Ferns*, and other plants.

From the plants mentioned it will be seen that a fine display of flowers will be had during winter and spring, while a dozen or more species of *Lilium* will make an effective show in summer.—W. D.

HORTICULTURAL SHOWS.

TORQUAY.

THE eighth show promoted by the Torquay District Gardeners' Association, of which Mr. F. C. Smale is the efficient Secretary, was held last week, and considered superior to all its predecessors. Entries were more numerous than at any previous time, and the competition was both larger and keener and the classes more generally filled.

A welcome alteration was made in connection with the groups, which, instead of being arranged in a circle, were elliptical, the first prize being noteworthy for a triple top, in which the centre Palm was flanked by two charming *Azaleas*. In the classes generally the quality showed an advance on former years, many of the plants being immensely improved on previous displays. Probably the table decorations attracted most attention and criticism. The eight designs stretched down the greater part of the room. The premier award was to an arrangement of *Daffodils* that won on its simplicity, though many preferred a light combination of *Narcissi*, *Jonquils*, and *Lilies of the Valley*, which was placed second. Red *Azaleas*, with *Spiræas* and Guinea Grass, made a very bright third, and the fourth award consisted mainly of *Violets*, *Daffodils* and *Orchids* being fifth.

The chief competitors were Dr. W. Ford Edgelow (Mr. C. R. Powse, gardener), J. W. Kimber, Esq. (Mr. F. C. Terris), Mrs. Rawson (Mr. W. R. Satterly), Miss Lavers (Mr. G. Lee), P. W. Bushby, Esq. (Mr. F. Peacock), Mrs. R. Whitehead (Mr. G. Green), and Mrs. Hassall (Mr. W. H. Minifie, gardener). Among honorary exhibitors were J. Snelgrove, Esq. (Mr. W. Bale, gardener), Mrs. Wilson (Mr. C. B. Elliott), Miss Lavers (Mr. G. Lee), and J. W. Kimber, Esq. (Mr. F. C. Ferris). Miss Lavis' *Orchids* evidenced considerable care and attention. Mr. Snelgrove's collection was selected and arranged with great taste. The Judges were Messrs. J. D. Nanscawen, Chudleigh; D. C. Powell, Powderham; and C. Lock, Crediton. Specimens of Egyptian Papyrus,

or Paper Reed, as used by the ancient Egyptians, were shown by Mrs. Wilson. Messrs. Curtis, Sanford & Co., Ltd., had some fine *Roses*; the South Devon Fruit Farm large luscious *Strawberries* at 5s. a basket, and beautiful *Violets La France*; other nurserymen represented being Messrs. T. S. Ware, Ltd., Tottenham; Veitch & Son, Exeter; W. B. Smale, W. Allward, J. Heath, Horn & Sons and W. Burridge & Sons.

Lady MacGregor, in opening the Exhibition, said she could scarcely realise that a year had passed since she last had the pleasure of seeing their show. But the winter passed so mildly and quickly in Torquay, that spring came before they were aware of it. They all loved the spring flowers because they showed that winter was passed, and because they were distinguished for the delicious odours and delightful colours with which Nature had endowed them. She thought the greatest encouragement should be given to the Association for arranging the shows and making them so attractive.

At the luncheon the President, Dr. R. Hamilton-Ramsay, in proposing the Royal Family, said that the day-before the Princess of Wales left England for a trip in the Mediterranean she honoured their President by sending him a most magnificent photograph of herself, with an autograph letter expressing admiration for the flowers he sent her every year—her

FIG. 64.—RHODODENDRON TRIFLORUM.

favourite flower, *Lilies of the Valley*, which this year were grown by the founder of the Association, Mr. W. B. Smale, J.P., their Vice-President (applause). Mr. W. A. Masterman, in proposing "Success to the Show," said it was one of the very best they had ever had. Great credit for its success was due to Mr. Fred. C. Smale, who made one of the best Secretaries they could possibly have. Mr. Veitch, in proposing the health of the President, eulogised his services highly. Dr. Ramsay, replying, said no one could be asked to be President of that Association without being highly honoured. The admirable way in which the Committee and others worked together with the skilful whip of their Secretary assured success. He thought the Show the most beautiful he had ever seen.

BRIGHTON AND SUSSEX:

THE eighth annual show of the above Society, held in the Dome and Corn Exchange last week, was a great success. Through being a fortnight earlier than usual, *Cinerarias*, *Roses*, *Auriculas*, *Azaleas*, and *Pelargoniums* were not shown to the best advantage, but, on the other hand, *Hyacinths*, *Tulips*, and *Narcissus* were much better than usual.

Groups are always good at Brighton, and in the open class, 13 feet by 8 feet 6 inches, the first prize was awarded to Mr. E. Meachen, gardener to Mrs. Armstrong, Woodslee, Withdeane, for a very light, bright, and attractive arrangement of foliage and flowering plants. Mr. J. Hill, gardener to Clarkson Wallis, Esq., Springfield, Withdeane, was second; and Mr. G. Miles, nurseryman, third. In the second division, for gentlemen's gardeners and amateurs, 10 feet by 6 feet, Mr. W. E. Anderson, gardener to B. Parish, Esq., Preston Park, was placed first with a taste fully arranged group; and Mr. G. Simms, gardener to J. B. Cattle, Esq., Dyke Road, Brighton, second. Tables of plants arranged for effect made an attractive display. In the open class Mr. G. Miles was first with a neat arrangement of *Lily of the Valley*, *Hyacinths*, *Primulas*, *Imantophyllums*, with small *Crotons*, *Aralias*, *Dracænas*, *Ferns*, &c. Mr. B. Lister, gardener to E. A. Willis, Esq., Brighton, second; and Mr. W. Goodliffe, florist,

Worthing, third. In the smaller class for gardeners and amateurs the successful exhibitors were Messrs. A. J. Blake, W. E. Anderson, and L. Wickens respectively.

Hyacinths made a good display. For twelve plants, not less than six varieties, Mr. A. E. Golding, gardener to Mr. H. St. George Voutes, Brighton, was first with Charles Dickens (pink) (2), Alba Superbissima (2), La Grandesse (2), Queen of the Blues (2), Grand Lilas, Lord Macaulay, Baron Van Tuyll, and King of the Blues; second, Mr. J. Harper, gardener to E. A. Tucker, Esq., Preston; third, Mr. W. Goodliffe. For six distinct, first, Mr. B. Lister; second, Mr. F. Rapley.

Tulips, twelve pots.—First, Mr. W. E. Anderson, with Joost Van Vondel, Thomas Moore, Duchesse de Parme (2), Keizers Kroon, Cottage Maid, White Pottbakker (2), Proserpine, Van der Neer (2), and Bronze King; second, Mr. J. Harper; third, Mr. J. Hill. For six pots.—First, Mr. B. Meachen; second, L. Wickens.

Narcissus were good. For twelve pots, not to include Polyanthus varieties.—First, Mr. J. Harper, with Horsefieldi (2), Figaro, Sir Watkin (2), Emperor (2), Frank Miles, Empress (2), Cynosure, and Barri Conspectus; second, Mr. C. Smith, nurseryman. For twelve pots of Polyanthus varieties Mr. J. Harper was again first, Mr. A. E. Golding second. For six pots any varieties.—First, Mr. W. E. Anderson; second, Mr. B. Lister.

Cinerarias.—Mr. Jas. Pearl, gardener to R. Y. Bevan, Esq., Witheane, was first for twelve with plants scarcely at their best; second, Mr. E. Meachen. Mr. G. Simms was first for six plants, the best in the show, and Mr. J. Hill second. Lily of the Valley and Spiræas were well shown. With the former Messrs. W. Miles & Co. secured the first prize in the open class, and Mr. E. Meachen in the class for gardeners; in the latter the Brighton Florist Stores were first in the open division, and Mr. B. Lister in the gardeners' section. Callas made a fine display at the end of the Corn Exchange, Mr. Anderson taking first for six with remarkably fine well bloomed plants in 10-inch pots; second, Mr. B. Lister; third, Mr. J. Harper. Mr. E. Meachen was first for nine Azaleas, distinct, also for six well flowered Deutzia gracilis, and six pots of Solomon's Seal. Mr. C. Murrell, gardener to Mrs. Jenkins, Franklands, was first for twelve Cyclamens, really grand plants, and Mr. H. Head, nurseryman, first for twelve Genistas, well grown plants, in 8-inch pots.

For a table of Orchids arranged with Ferns Mr. Goodliffe was placed first with a tastefully arranged display, consisting of Dendrobium fimbriatum oculatum, D. nobilis, Cattleya Trianae, Odontoglossums, Cypripediums, and others; second, Mr. H. Garnett, gardener to R. Fletcher, Esq., Mount Harry, Brighton, whose collection included fine plants of Cattleya Trianae, Odontoglossum crispum, O. Andersonianum, Cypripedium Bovali, and Dendrobium nobilis; third, Mr. J. Harper.

Cut flowers were not numerous. For twelve varieties Mr. H. Garnett was first, consisting principally of Orchids. Second, Mr. J. Harper, who also took first for cut Narcissus. Miss M. Baldock was first for table decorations with a light arrangement of Miss Jolliffe Carnations, Lily of the Valley, and Narcissus poeticus ornatus, with Ferns and Caladium argyrites. Second, Mr. E. Meachen; third, Mr. F. Rapley.

Silver-gilt medals were granted to Messrs. Balchin & Son and Messrs. Boldock and Croysdel for valuable non-competitive exhibits, and silver medals to Messrs. Webb & Sons, Stourbridge, for a collection of Cinerarias, well bloomed plants of a good strain, and a large collection of Hyacinths; to Messrs. Cutbush & Sons, Highgate; Mr. W. Goodliffe, Worthing; and Mr. A. Kemp, Coothurst, Horsham, for a fine collection of Alicante Grapes, twenty-five dishes of remarkably well kept Apples, also twenty-five varieties of Potatoes, clean and even tubers.

THE YOUNG GARDENERS' DOMAIN.

SEAKALE.

AFTER reading Mr. D. Thomson's remarks on page 202, I must confess that we young gardeners have "almost entirely ignored" the kitchen garden department. I am therefore sending a few remarks on the cultivation of Seakale, which I think I may safely say is one of the most highly appreciated winter vegetables. It is of extremely easy culture, as given strong land, well manured and fully exposed to the sun, satisfactory results may be expected.

The best time to plant Seakale is during the month of March, in ground that has been trenched two spits deep, and has had a layer of manure placed between the spits. As strong plants, when in full growth, take up a considerable amount of space, they should be planted from 2 to 2½ feet asunder in rows 1 foot 9 inches to 2 feet apart. The crowns must be buried about 2 inches below the surface. When the roots are growing, care should be taken to remove all flowering shoots, as these, if allowed to remain, will prejudice the crop of the following season. The growth may be materially helped by the use of liquid manure or good mulchings of manure during the growing season. In the autumn when the leaves decay they must be removed at once, and the plot be kept free from weeds and rubbish. Later the crowns ought to be covered with a ridge of leaves weighted with a sprinkling of soil, to prevent them being blown away by the wind.

At the proper time place Seakale pots or boxes over the crowns, and cover these with leaves or straw to encourage an early start. The plants must be kept perfectly dark, or the Seakale will be improperly blanched. Under this system when ready for use it will be found far better than if the plants had been lifted and forced, inside. When all the growth has been cut from a crown, remove the pot or box, and apply a covering of leaves or straw for protection.

If Seakale must be forced quickly, lift a number of roots, and put them in pots in soil or leaves in a temperature of from 55° to 60°, keeping perfectly dark. After the roots have been forced inside they will be of little further use, and should be thrown away. I may state that in the Seakale plantation the spaces between the rows can be used to advantage for Lettuce, Radish, or some such quick growing crops.—ONE OF THE YOUNG SCHOOL.

FRENCH BEANS.

FRENCH Beans constitute one of the most valuable vegetables in cultivation if obtained early, and they are well worthy of a few cultural notes. For the earliest crops seeds must be sown in 8-inch pots, but later in the year they can be grown in beds in heated frames until it is safe to sow out of doors. At the beginning of the year the earliest should be sown in clean and well-drained pots, with a little soot spread on the crocks to prevent the ingress of worms.

Place from ten to twelve beans in each pot, using a compost of three parts loam cut up roughly, and one part sweet horse droppings, with a little old mortar rubble and wood ashes incorporated, making it firm in the pots with a rammer, covering the seeds about half an inch. Give a good watering, and afford them a temperature of 60° to 65° at night, 65° to 70° by day, keeping the pots as near the glass as possible. Very little water will be required until the Beans appear above the surface, and then it should be carefully afforded. Syringe the plants in the morning and at midday when the weather is bright, and it will be found beneficial to them if some weak liquid manure is syringed between the pots two or three times daily. A little thinning will be required, leaving about eight plants in each pot, as abundance of air is essential to success. It will be necessary to stake the plants to prevent them falling down over the pots, and pieces of old birch broom will be found suitable for the purpose.

When the plants come into bloom keep the house somewhat drier, and give the pots a little shake about midday. Apply weak liquid manure when the Beans are set, increasing its strength gradually. Treating them in this manner they can be obtained fit for use from seven to eight weeks from the time of insertion, and fortnightly sowings can be made for succession.

As the days get longer and the sun gains power the seeds may be sown in heated frames in rows 18 inches asunder and an inch in depth. Do not sow too thickly, and give a thorough watering, treating in the same manner as stated for pot work. For outdoor crops the ground should be well manured and deeply dug at the beginning of winter, so that the frost can get well into it. The end of April or the beginning of May is a safe time for sowing. Have the rows 2 feet apart, and cover the seeds about an inch. After the plants appear above the surface and the rows can be distinctly seen, hoe between them to destroy any weeds that are coming up, and loosen the surface soil. If the weather become very hot an occasional watering will be of material benefit to the plants. Gather the pods as they become large enough, as if the seeds swell in them flowering will cease—P. R.

DECORATIVE CHRYSANTHEMUMS.

MUCH time and interest are centred on Chrysanthemums for exhibition purposes, but it must not be forgotten that the decorative section renders invaluable service throughout the winter months. The plants are indispensable for the supply of cut bloom, and provide unsurpassed brightness in the conservatory. It is not my intention to give a list of varieties, as this would be a difficult task considering all those now in cultivation, while tastes differ so much that individual selection is the most satisfactory.

To obtain the best results the cultural conditions must be strictly regarded. Propagation by this time being completed, we may assume that the plants are rooting well in small pots, and as it is requisite to have plants of bushy form, it is advisable to stop them without delay, thus allowing sufficient time to overcome this check before being placed in 6-inch pots. Pinching must be completed in three operations, the last being in the second week of June, but for later display a little postponement beyond that date will be advantageous.

After the plants are placed in 32-pots there must be ample ventilation in the frames, removing the lights on favourable occasions, so as to induce sturdiness and insure sufficient hardening to place the stocks in a sheltered position out of doors about the middle of April, where they may remain until the final potting. A substantial compost must be employed at this stage, consisting of three parts of fibrous loam, one part each of leaf mould and partly spent horse droppings, with half a part each of wood ashes and old mortar rubble, good road grit or silver sand completing the mixture, though a 48-potful of half inch bones or bonemeal to a wheelbarrow of soil is often added. After the final potting a more open situation is needed, exposing them to full sunshine, as well-ripened wood is essential. Attention must be paid to staking and tying.

With the abundance of growth, coupled with vigorous root action, feeding is absolutely necessary. Liquid manure from the farmyard and soot water are the safest at the outset, varying the foods according to convenience as progress is made. A good plan is to apply, when there is evidence of a steady rain, a dusting of soot over the surface of the soil, or a top-dressing of a well recommended artificial manure, as such will prove of great benefit.

Insect pests are at all times troublesome, the tobacco puff being of immense service for the destruction of green or black fly infesting the points, and occasionally syringing with quassia will frustrate their ravages to a large extent. Flowers of sulphur must be used if mildew appear, dusting freely into the middle of the plants. Remove all decaying leaves to arrest the spread of this enemy.—F. W. G.

HARDY FRUIT GARDEN.

Grafting Fruit Trees.—The most suitable period for grafting is when the sap has risen in the stocks, causing growth to commence. It is then certain that the sap will continue active, and under favourable conditions the success of the operation of grafting will be assured.

Forms of Grafting.—The most common forms of grafting are the side or whip grafting for young stocks, and the crown or rind grafting for stocks over an inch in diameter.

Side or Whip Grafting.—With this form of grafting the stock is worked very low. Select a point where the bark is very smooth, and as near to the ground as possible. Cut off the head of the stock in a slanting direction, making a clean cut about 3 inches long. Side or whip grafting necessitates that the scion should be of the same thickness as the stock; therefore, suitable healthy growth of last year should be selected. It must be about 6 or 8 inches in length and have quite dormant buds, which means that the sap in the scions is practically inactive. The buds, too, must be wood buds. In preparing the scions select that part on each shoot where four of the best buds are situated. This is usually the central part, where the shoot is straight, the buds ripe and bold, and the wood firm. Make a slanting cut downwards in the scion of the same length as that in the stock. Unite both closely and evenly and secure firmly. Cover the parts with clay or grafting wax, and soil may be heaped round if the working is carried out close to the ground.

Crown or Rind Grafting.—Large old trees headed down some time ago may now have a fresh slice taken off in readiness for grafting. It is an excellent method of placing good varieties on clean healthy stocks. The bark must be smooth. Select well-ripened, short-jointed scions, cut from the central parts of last season's shoots. Four buds ought to be present on each. Make a slit downwards in the bark of the stock, just through the bark. Cut the scion the same length as the slit in the stock, making a clean slanting cut downwards; and at the upper edge form a small shoulder for resting upon the stock, which will keep it securely in position. Insert the scions carefully, and work them into position until the shoulder rests upon the flat surface of the stock. Several scions may be placed on large branches, and the lot tied in together, using some soft ligature. The parts must meet as exactly as possible, in order that a good union may be effected. Cover all the joinings with grafting wax, also the top of the stock, so that air will be excluded and the parts kept moist. The retention of moisture about the parts is facilitated if moss is tied round and occasionally wetted.

Grafting Wax.—As a rule grafting wax should be used warm. One part each of resin and yellow wax should be melted in an earthen pot over a fire and used warm, but not hot so as to injure the bark. Wax which may be used cold is very convenient and is made as follows:—1 lb. each of yellow wax and turpentine; $\frac{1}{2}$ lb. of Burgundy pitch, and $\frac{1}{2}$ lb. of mutton suet. Melt and mix thoroughly, allowing to cool. It is best formed into small balls to be handy for use.

Watering Fruit Borders.—The soil of the borders close to the wall in which fruit trees are growing, especially Peaches, Nectarines, Apricots, Cherries, and Plums, is often much drier in spring than it ought to be, hence it is not surprising that later on insects will abound, including the numerous species of the aphid family and red spider. These do immense damage and cripple the foliage, so that it cannot perform its functions of building up the buds for next season. Examination of the borders ought occasionally to be made, winter as well as summer, and in mild periods during the former season water and liquid manure may be freely applied. At the present time a copious supply of clear water to the borders that are at all dry, would be extremely beneficial. Unless the surface is full of roots the top layer of soil may be removed down to the roots, so that a fair sized dish is formed which will hold plenty of water. Fill this several times with clear water, and afterwards with liquid manure. Close to the wall must necessarily be the driest part, so water should reach there freely.

Top dressing Wall Trees.—After well moistening at the roots the soil must be returned, but if that removed was poor and exhausted it will be desirable to supply fresh material. For stone fruit trees make up a compost consisting of substantial loam, adding one-fifth of wood ashes, a good sprinkling of crushed mortar rubbish and crushed bones. Mix thoroughly and place firmly over the roots as far as they extend. Manure, even if well decomposed, should be used sparingly in the preparation of any compost. A little will improve poor loam, and benefit old trees which require stimulating. The growth of young trees, however, needs subduing, and not increasing by manure in the soil. It is safe to apply a rich compost over the roots of heavily cropping Apples and Pears, or where the growth is weakly and requires to be improved.

Strawberries.—Strawberries may yet be planted, but strong plants should be placed out, if possible with balls of soil attached to the roots. Those which are not thus furnished must have the roots spread out in the soil. Plant in firm ground, give water in dry weather, and mulch lightly. A dressing of soot, a peck to the rod, may now be given to fruiting plants two or three years old. After that application give a mulching of rich manure between the plants. A mixture of long and short manure combined is the best.

FRUIT FORCING.

Cucumbers.—Shade will be necessary from bright sun during the prevalence of keen northerly winds, as air can only be given very moderately. The shading, however, should only be used for a few hours at the hottest part of the day, and only sufficient to prevent flagging. Assist plants in full bearing with applications of weak tepid liquid manure, and add fresh warmed soil to the beds occasionally. Thin out the exhausted growths of plants that have been in bearing some time, and encourage fresh bearing shoots. Damp the floor in the morning between seven and eight o'clock, and again in the afternoon about three o'clock, syringing the foliage gently on warm afternoons, and keep liquid manure in the evaporation troughs. Attend to stopping, thinning and training at least once a week. Maintain a night temperature of 70° to 75°; by day, 80° to 90° with sun, and close sufficiently early to maintain the latter degree, or even rise to 95° or 100°, with an abundance of atmospheric moisture.

Pits and Frames.—Maintain the requisite heat by renewing the linings. Train the growths rather thinly, pegging them down as required, and stop one joint beyond the show for fruit, or the leading growths 12 to 18 inches from the sides of the frame. Add fresh warmed soil to the ridges or hillocks as the roots extend. Be moderate in the application of water, as the nights are cold, and employ thick night coverings. Admit a little air early, so as to have the foliage dry before the sun acts powerfully upon it. The heat through the day may range from 80° to 90° with sun. Close early in the afternoon, no harm accruing if the temperature rise to 90° or even 100°, provided there is no rank steam. If there is danger from it admit a little air constantly, a small opening being sufficient to allow it to escape.

Peaches and Nectarines.—*Earliest Forced Houses.*—The very early varieties will soon give indications of ripening, when syringing must cease, and the leaves that shade the fruit should be drawn aside, raising the fruit, if necessary, on laths placed across the trellis wires, so that its apex will be directly to the light. Do not hurry successional varieties during the stoning process, but continue the temperature at 60° to 65° at night, 70° to 75° by day with sun heat, and 65° by day in dull weather, avoiding sudden fluctuations and depressions. Tie the shoots to the trellis as they advance, and regulate the growths for future bearing so as not to have them too crowded. Shoots disposed to grow more than 14 inches may have the points pinched off, but extensions should be trained in their full length. When the stoning is over the crop will require thinning for the final swelling. Very vigorous trees may be allowed to carry more than one fruit to each square foot of trellis, while weaker trees should not be permitted to bear so many. Supply liquid manure to weakly trees, the inside border in any case being kept properly watered, mulching the surface with a little decayed manure. This will secure uniform moisture, and favour the surface roots.

Trees Started at the New Year.—The fruit should be regulated to a few more than will be required for the crop. Avoid sudden checks by judicious ventilation, cold air and a light temperature at night proving fatal to the fruit stoning. A night temperature of 60° to 65°, 5° less on cold nights, and 65° by day in dull weather, with 70° to 75° from sun heat, is quite sufficient. Of course the temperature will run higher on bright days, but let it be with full ventilation.

Trees Started Early in February.—Syringe the trees occasionally in dull weather, and twice a day in bright, but avoid heavy syringings, especially late in the afternoon, as the water remaining long on the foliage interferes with the elaborating functions, and may destroy the tissues. Allow a night temperature of 55° to 60° in mild weather, ventilating from 65°, permitting an advance to 70° or 75° from sun heat, but with full ventilation. Attend to disbudding, and follow it up day by day until all the shoots not required for future bearing or the extension of the trees are removed. A shoot must be left at the base of those now bearing, and another on a level with or above the fruit. If the latter is not required for extension it should be stopped at a few joints of growth. In the case of trees not full grown it will be necessary to have shoots about 15 inches apart, calculating from the base of the last year's growth, to form the bearing shoots of next year, the terminals being trained in their full length as space permits. Avoid crowding the growths, as they become weak and unfruitful. Commence thinning the fruits when they start swelling. Laying in the shoots requires to be done early and carefully, so as not to bring them down too sharply, yet it is necessary for giving the right direction to the growths, and in securing the shoots to the trellis space must be left for their swelling.

Trees Started in March.—While the trees are in blossom it is not advisable to syringe them, but a genial condition of the atmosphere may be secured by damping the paths and borders in the morning and early afternoon. Prevent a vitiated atmosphere by providing a little air constantly through the top ventilators. Maintain the night temperature at 50°, falling 5° through the night in severe weather, 50° to 55° by day, and 65° from sun heat.

Latest Houses.—The blossoms being abundant remove those on the under side of the shoots. Shake the trees daily from the first pollen ripening until the last of the blossom requires attention, selecting the early part of fine days. When artificial impregnation is resorted to it is a good plan to dust every blossom, when the pollen is ripe, with a camel's-hair brush, a feather, rabbit's tail mounted on a stick, or small plume of Pampas Grass. Any trees deficient of pollen should have it taken from those affording some plentifully, such as the small-flowered varieties—Royal George and Elruge Nectarine. Maintain the temperature at 40° or 45° at night, 50° to 55° by day, in all cases accompanied by slight

ventilation at the top of the house, which must be increased when the temperature reaches 50°, and full at 65°.

Unheated Houses.—The trees are coming into blossom. Ventilate the house at 50°, and do not permit an advance above 65° without full ventilation top and bottom, and close the house at 50° in mild weather, but when there is a prospect of frost at night close at 65°, leaving a little air to allow of moisture escaping. In mild weather leave the ventilators open constantly when the temperature exceeds 50°. Remove the blossom on the under side of the shoots where there is a superabundance. See that the borders are in a proper state of moisture, supplying water as required or liquid manure to weakly trees.

THE BEE-KEEPER.

THE WEATHER.

BEES, as well as vegetation, have received a serious check, owing to the sudden change that has taken place in the weather. The extreme mildness of the past winter had enabled bees to commence breeding at an early date, and the brood nest was enlarged more than is usual at the present time. Now all is changed; a severe frost, followed by a heavy fall of snow, has been general throughout the country. In a sheltered spot near our apiary 13° of frost have been registered. At the time of writing the ground is covered to the depth of several inches with snow, and this will have the effect of protecting vegetation, which had already become very forward.

In all cases where the hives are now covered with snow, it will be advisable to clear it away from the roofs as well as the entrances. If at midwinter there is a prolonged frost, it is advisable to allow the snow to remain on the roofs, as it forms a warm covering so long as the weather is dry; but at this season the sun increases in power daily, which will have the effect of partially melting the snow, and if there is a weak place in the roof, moisture will penetrate into the interior of the hive. If not already done, the entrance should be reduced to half an inch. It is also an advantage to shade the entrance so long as snow is on the ground. A piece of wood or slate placed in a slanting position on the alighting board, so as to prevent the rays of the sun striking directly on the entrance, will answer the purpose admirably, and will be the means of preventing the bees from being attracted by the glittering snow, and thus becoming numbed, and unable to return to their hive. It is hoped, however, that by the time these lines appear the snow will have departed.

Bees should not be uncovered or handled whilst a low temperature prevails, as they will be warmly clustered in the middle of the hive, and if they have ample stores the brood will not become chilled. Directly, however, a change takes place in the weather no time should be lost in seeing that all are well supplied with stores according to advice given in previous notes.

PACKING BEES.

Bees are often sent from one part of the country to the other, and when in straw skeps they may be packed with very little trouble. In the case of old stocks the present is the best time in the year to carry out this operation, because the bees at this season ought to be fairly numerous, but not unduly so; there will be a small quantity of brood, but not sufficient to become damaged in transit, and owing to the paucity of bees, and a comparatively low temperature, they will not become so excited as when the hive is overflowing with them and a high temperature prevails. But whether a stock is weak or strong, the same care is necessary to insure free ventilation. This can only be done by packing the skep bottom upward. If sticks were not placed across the skep when the bees were put in it, one at least must be driven through the side of the skep about 3 inches from the bottom, and forced through the combs until it passes through the other side of the skep. This will hold the combs in position and prevent breaking in transit.

Invert the skep and place a piece of cheese cloth or some other open material over it. This should be securely tied with small string round the outside. Now have twelve strong laths cut the same depth and breadth as the skep. Nail them together so as to form a skeleton box. Cross them at the bottom and also at the top, and place the inverted skep inside. The ends of the laths should be nailed, and round the whole a piece of cord ought to be tied to carry it by. The skep will thus travel upside down, and should they remain in this position for several days the bees will be found to be in good condition at the end of their journey.—AN ENGLISH BEE-KEEPER.

ABUTILONS.—These plants may be grown from seed, and the plants will in due course flower freely. Sow in pot of light sandy soil at the present time in a greenhouse temperature. When the seedlings have attained to the height of an inch, prick them out in other pots. The next move must be to small pots, transferring afterwards into larger pots.—S.

•• All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," 8, Rose Hill Road, Wandsworth, S.W., and NOT to 12, Mitre Court Chambers, Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *nom de plumes* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Mushroom Spawn (H. E. C.).—The spawn has, as you say, a stale mouldy appearance, and not that aroma of Mushrooms, which we like to find in all samples, as indicating freshness and life. The threads or mycelia, however, appear alive, and though the older or larger may not further develop, the fine threads would probably do so. Still we should have liked the bricks fresher, though we cannot go so far as to condemn them. We have found it an excellent practice to test the bricks or spawn in all cases of doubt by making up a slight hotbed of the prepared material, and spawn it in due course, when if the spawn be good it will lay hold of the fresh material in a few days, and the spawn can be used with confidence; or if, on the other hand, the spawn dies, as it certainly will if too old, the bricks can be discarded as worthless, and trouble avoided. We always make a rule of getting a forecast of the crop in the smell of the bricks. If they have a very decided Mushroom odour the spawn is quite fresh, and only needs opportunity to develop, and produce under good management an abundant crop of Mushrooms. If there is not more than a fusty smell, though it may produce some Mushrooms, we consider it cannot give a full crop. It is prudent to procure samples of spawn before ordering on a large scale.

Sowing Peas (O. F.).—Many Peas are sown too thickly in the drills for the development of robust, productive plants, and the rows are very often seen too close together. Given deep, rich soil that contains moisture in dry weather, good results are had by sowing bold new seeds 2 inches apart over the surface of flat drills 4 or 5 inches wide, or the width of the boot of the workman as he runs it along the drills to make an even base for the Peas to rest on. At this period of the year they may be covered about 2 inches deep, or rather more if the soil is of a light nature. As the season advances they may be covered an inch deeper with advantage. Where mice or other enemies abound Peas are often sown more closely in the drills, to allow of some being taken, yet sufficient escape to produce full rows. If practically all grow under this close sowing, then some of the plants should be thinned out when an inch or so high. Moistening the seeds with petroleum and dusting them while wet with powdered red lead is, however, an excellent preventive of the attacks of mice and feathered enemies. If several rows are grown on a plot of ground the distances between them should exceed the height of the varieties. Instead, for instance, of having the rows of tall Peas 3 or 4 feet apart it is much better to allow as many yards between them, cropping the wide spaces with Potatoes or other low growing vegetables. When it is convenient, some amateurs find it advantageous to have rows of Peas near the margins of the vegetable ground, or alongside the paths. The plants then, through full exposure to light and air, become short jointed for the variety, and produce more and bolder flowers and pods than they can possibly do when drawn up in a spindly manner by overcrowding. The best possible seeds of all kinds sown somewhat thinly give far better results than the cheapest possible inferior seeds sown very thickly.

Pruning Cotoneaster and Privet (Idem).—Cotoneasters only require pruning to keep them within desired bounds, and this may be done at the present time. Privet may also be pruned to any required extent now; but to keep Privet hedges in good condition, they should be neatly clipped about the middle of June, or sooner if the growth is free, and again towards the end of August. Overgrown bushes or hedges may be cut into shape any time in April.

Weevil and Maggots (Parvo).—The "beetle" is the destructive weevil *Otiorhynchus sulcatus*, and the grubs are its larvæ. These devour the roots of many kinds of plants, and the weevils eat the leaves of Vines, Ferns, Roses, and other plants. Several may be caught at night with the aid of a bull's-eye lantern suddenly turned on them. For dealing with the larvæ see reply to a correspondent on page 136, February 16th. Your letter arrives too late to be more fully answered this week.

Imported Orchids (Subscriber).—Nearly all the principal nurserymen can supply newly imported Orchids at the proper season for each species, and the following occur to us as specialists:—Messrs. Sander & Co., St. Albans, Herts, and Hugh Low & Co., Bush Hill Park, Middlesex. Messrs. Prothero & Morris are always open to buy on commission, and in your own neighbourhood you have the Leeds Orchid Company. If you are only growing six species you could not do better than choose from the deciduous group of Dendrobiums, all of which are fine for cutting for buttonholes. Six of the finest are *D. Wardianum*, *D. crassinode*, *D. Ainsworthi*, *D. Pierardi*, *D. Devonianum*, *D. Dearei*; the last is a late summer flowering species, but one of the very best. We do not undertake to reply to questions by post, and moreover, you did not enclose a stamped directed envelope.

Black Flies from Manure (T. E.).—A number, sometimes swarms, of small black flies appear from fermenting beds in houses, and they spread over the plants, no matter of what kind, in the structure. We have not found them develop into "maggots," which is the wrong way about, nor have we known the least harm accrue from them. They are only too glad to get into the fresh air; but, of course, the weather lately has been of such nature as to prevent the admission of air, hence they swarm over the plants in the house. As you have found maggots they must have come from eggs, but you neither send flies nor maggots. These may or may not be of an injurious nature, but the flies certainly succumb to fumigations, and the maggots must live on organic matter, but whether on dead or living we cannot say, yet we think you are needlessly alarmed. For destroying red spider on the Strawberries clear soot water, made from fresh soot, is excellent. Spidicide has a very decisive effect on red spider, but it can hardly be used on the fruits, and similar remarks apply to insecticides generally. A peck of soot to 30 gallons of water, stirred well every day after mixing at first, not leaving any to float on the top of the water, for four days or a week, then allowed to clear, will give a good account of the red spider, using it on the under side of the leaves, and keeping it from the fruit, as much as possible. Even syringing with clear rain water has a good effect, and is in most cases sufficient to keep the pests under.

Pruning Newly Planted Climbing Roses (Mrs. Mason).—Assuming the Roses you planted several weeks ago were dug from the open ground, the closer in reason you cut the 6 feet long stems back the better the growth will be this year, and the sooner the plants will produce the hoped-for masses of flowers. We planted some climbing Roses in the autumn. They had grown vigorously in the nursery, producing stems from 5 to 8 feet long, but the roots, in consequence of digging up the plants, were not a foot in length. To have expected such a paucity of roots to support such long stems and produce healthy growth in addition would have been futile; we therefore cut the stems down to 2 feet or less at the time of planting, and now the top buds on the shortened stems are pushing from half an inch to an inch in length. As there would be danger of these precocious growths being crippled by frosts still to come, we shall, in the course of a week or so, cut the stems back still further to bold dormant buds from 6 inches to a foot from the ground. By concentrating the root force on these few and later buds, we shall expect them to produce strong growths during the season, whereas had the last year's stems been left their full length, as yours are now, puny growths, or none, would have been the result. It is not necessary to cut back so closely Roses that have been grown in pots for a season, because practically all the roots can be preserved when planting, but even then cutting back some of the stems rather closely is in most cases advantageous.

Grass under Trees (R. L.).—Grass does not, as a rule, grow well under trees, partly from the shade and drip of these, and partly through the dryness and pooriness of the soil. We have found it an excellent plan to give the ground under trees a good dressing of a mixture in equal parts, by measure, of air-slaked chalk lime, soot, and wood ashes, applying a peck of the mixture per rod (30½ square yards), and afterwards placing on a light dressing of rich compost, not much, but just sufficient to lightly cover the ground, and admit of raking without leaving a soily appearance. The lime, soot, and wood ash mixture is best given in February, also the top-dressing of rich compost, such as rubbish heap débris, leaf mould, thoroughly decayed manure, or a mixture of the three, in March, raking well, and at the end of the month or early in April sowing on it grasses that succeed fairly well in the shade, such as *Poa nemoralis sempervirens*, *Festuca rubra*, and *Aira flexuosa*, with an equal proportion of *Lolium perenne*. These grasses have given fair results, and a good turf where not greatly overhung by trees. The proportions to use are equal parts by weight of the first three, say 2 lbs. each, collectively 6 lbs.; then sow separately the same weight of the *Lolium perenne* or Perennial Ryegrass, which grows quickly, "tillers" well, and protects the other grasses. Rake lightly after sowing and roll well. It is important to sow rather early and get the grasses up before the trees come into leaf. For ordinary renovation the mixture suffices for an acre; if the present grass is thin, use double the quantity, and if there is scarcely any grass, double again, or 48 lbs. of the mixture in the proportions given per acre. We have used as much as 60 lbs. per acre, and even on a small scale, to get a good turf quickly, ½ lb. per rod.

Names of Plants (J. T.).—1, *Pteris a-pericaulis tricolor*; 2, *Blechnum brasiliense*; 3, *Lomaria gibba*; 4, *Maranta (Calathca) zebrina*; 5, *Sansevieria zeylanica*; 6, next week.

WHAT IS THE VALUE—

WHAT of the new bill now before Parliament relating to the adulteration of food? That certain classes of food are much adulterated is beyond question; the difficulty is to prove the adulteration and to bring the culpable person within reach of the law. It is so unfair to the public that they should lay down money (good money) for that

which is not food, or rather, even, we may go so far sometimes, and add for that which is really detrimental to the system.

The portion of the public that suffers most is that portion, as a rule, least able to defend itself—the working class and young children. In the first place the poor customer is less liable to suspect mischief; in the second place he has a wholesome awe of law courts; and in the third he would find some difficulty in knowing to whom he should make his complaint. The law is hedged about, and it is only those in the “know” who can really penetrate into the maze.

The upper classes purchase their food supplies in large quantities and from assured sources, and if they for one moment suspect they are being “done” over any particular article, they are both willing and able to defend themselves, and will get at the reason “why.” Milk is an article that lends itself to adulteration—the process is so easy, detection so uncertain. We are happily past the days when chalk and brains and other delightful compositions might be found at the bottom of the milk can, but we are still open to other ingredients, which certainly are not what we expect we have paid for in the milk bill.

How can we increase our quantity of new milk without the addition of fresh cows in the dairy. Our cows, with judicious feeding, are doing their very best, the quantity is large, and the quality—i.e., the butter fat, is equal to, or rather above the average, the average being 3.75 to 4 per cent.; Jerseys will reach 5 per cent. Yet we want more. Naturally our customers desire at times several quarts over their usual order, and we are perplexed as to how to provide them with it.

Now comes in science to our help. We have an excess of butter fat, the accepted standard is 3 per cent. Our percentage is from 3.75 to 4 per cent., so as to have something in hand to work upon. Now comes into play the useful separator. The milk is warm, and being mixed up with the “real new” does not in colour or temperature betray itself; the flavour is distinctly different from skim milk that has had to stand, and age diminishes its pleasant properties. Now, no analyst can stand against this sort of fraud, and fraud it is. The only way to catch such vendors is to follow them to the mixing shed, and this is practically impossible. The new Act would allow the seller to add a little colouring matter provided it was not injurious; the same latitude is permitted in the matter of preservatives. Well, that may be all right, but we do not care to take ourselves and to put in our young children's food certain drugs which may or may not be undesirable. We would rather have the milk pure; if we want preservatives, let us add them ourselves, and in the quantities we think desirable.

How are we to know where this preservative business stops? We read of the farmer adding a mixture at the rate of 1 pint per churn, and then who knows how much more may be added by the retailer, and how much by the consumer? In the end it may be very heavily preserved and totally unfit for the delicate stomach of a baby or of the sufferer from dyspepsia. Boric acid seems to be the principal agent, and yet it is counted as not injurious here in enlightened England. Germany and Holland have forbidden its use in articles for home consumption.

What about the margarine business? It appears margarine may lawfully contain 10 per cent. of butter fat. Well, we have no fault to find with that. What we dislike is the butter which is impregnated with margarine, and it can be done, and to a great extent, without the slightest suspicion being aroused in the breast (or stomach) of the consumer. It is a punishable offence *if detected*, but who is to detect it? It would be very much after a case we heard of some years ago, when a seed crusher declared it lay in his power to grind up any substance to such an impalpable powder as to entirely defy detection. We must have margarine with a distinguishing colour, or the manufacture must be carried on in buildings open to government inspection.

It is all very well marking in large letters the paper wrappers; it is all very well appending name and address to milk cans and “separated” or skim milk to utensils containing those ingredients,

but still the public has much left in its own hands, and until there has been some swinging convictions and heavy fines the unjust vendor will but laugh in his sleeve, and pocket his gains.

The “Sheffield Evening Star” for March 17th says:—

Mr. Walter Long will not be allowed to conduct the Food and Drugs Bill through Committee without much discussion. Notice has already been given of nine big pages of amendments, and there is plenty of time for additions to the number.

WORK ON THE HOME FARM.

Farmers who have hurried on and almost, if not altogether, completed the spring sowings, will be chuckling at the forward position of their work now that winter has made a serious re-appearance.

The check, though to some people inopportune, can but be temporary with April so near, and with true April weather, the early-sown grain should do well, for this frost will prevent its getting too forward. The same may be said as regards fruit trees, which would soon have been in bloom, and therefore running great risk of injury from late frosts.

Wheat looks well, and is not losing root as it so often does; it is quite forward enough, and in some fields the plant is almost too thick; the prospect of a crop is decidedly good, but prices keep very unsatisfactory, with little hope of improvement.

The cold snap has had a weakening influence on stock markets, for roots are very scarce, and too many farmers have nothing now but pastures to depend on. Happy is the man who has a good heap of Mangold, with sufficient grass whereon to consume it, and so keep his sheep away from the young seeds until frost is past for the season.

Swedes are nearly finished, and in one way it is a good thing, for being small in the autumn, they were not stored, but allowed further opportunity for growth. They certainly gained in weight up to Christmas, but the mild winter has encouraged them to run, and the flesh has been more or less stringy and woody since mid-February. From this it appears that we should always store the Swedes for spring use, however small they may be at Martinmas.

The artificial manures, if not already bought, should be purchased at once, and immediate delivery should be insisted on. Superphosphate especially requires time to dry if recently dissolved, and where the farm is far from a station, it is bad policy to defer the carting in of the tillages until the time to sow them, for it is always a very busy one.

Land already prepared for Mangolds should not be ploughed again until just before drilling; but if the surface be a little rough, a harrowing and rolling, as soon as dry enough, will improve the mould, which will have later on to enclose the young seed. Farmers are now huying their seeds; may we urge on them the importance of buying nothing but the best?

REMARKS.

19th.—Bright and generally sunny.
20th.—Clear early, alternate cloud and sun after, with frequent sprinkles of snow in afternoon.
21st.—Foggy early; fair, with much faint sunshine till noon, then snow till 4 P.M. and fine again after. The grass min. thermometer was slightly covered with snow.
22nd.—Bright morning, cloudy at times in afternoon.
23rd.—Overcast, with frequent slight snow, sleet, and soft hail till 1 P.M. then generally sunny.
24th.—Brilliant morning; cloud and slight snow at 0.15 and at 1 P.M.; cloud and sunshine in afternoon; bright sun from 4 P.M.; fine night.
25th.—Overcast early; sun at 9, and cloud and sun till noon; fine rain in afternoon, and steady from 6.15 P.M. to midnight.
A very remarkable week for the latter half of March; it is the coldest since the last week in January, 1897, and the night minima are lower than in any week since the intense frost of February, 1895. Rain still very deficient.—G. J. SYMONS.

BARR'S PURE GRASS SEEDS

For Lawns, Tennis Courts & Cricket Grounds.

The following mixtures are composed of PURE GRASS SEEDS only, which have been thoroughly cleaned and carefully mixed. They cannot fail to give the most satisfactory results.

We sell the Seed by weight, which is the only correct method of estimating quantity needed for a given space.

BARR'S "THAMES EMBANKMENT" GRASS SEEDS, for Parks, &c.—A special mixture which has been found very successful in many public and private parks and squares around London and throughout the country. Per lb., 1/3; per 10lb., 10/6; per 20lb., 20/.

BARR'S "STANDARD" GRASS SEEDS, for Garden Lawns, Golf Links, Cricket Grounds, &c.—In this mixture there is a larger quantity of dwarf, fine-leaved Grasses than in Barr's "Thames Embankment." Per lb., 1/6; per 10lb., 12/6; per 20lb., 22/6.

BARR'S NEW MIXTURE OF DWARF GRASSES, for producing an Extra Fine Smooth Lawn.—A special mixture of the finest-leaved and dwarfest-growing Grasses, producing an EXTRA FINE VELVET TURF, and saving labour in not requiring frequent mowing. Per lb., 2/-; per 10lb., 18/-; per 20lb., 34/-.

Fuller particulars, with Hints on the Management of a Lawn, sent on application.

DICKSONS Nurseries CHESTER

HIGH CLASS

NURSERY STOCK.

LAURELS for single bushes, splendid heavy broad plants (not thin or weak), every one a specimen; all well rooted and with good foliage, of the hardiest varieties (no tender Common Laurels included), 2 to 2½ feet, 25/-; 2½ to 3 feet, 30/-; 3 to 4 feet, 35/- to 50/- per 100.

Thinner Plants for Covert Planting, &c., 2 to 3 feet, 16/-; 3 to 4 feet, 25/- per 100.

PORTUGAL LAURELS, very fine, 2 to 2½ feet, 6/-; 2½ to 3 feet, 9/- and 12/- doz.

AUCUBAS, well-coloured, well-rooted plants, mostly as wide as they are high; fine for ornamental grounds; stand well under trees; fine shrub for smoky situation, and if planted with male Aucubas beautiful for berries; 12 to 18 inches, 6/- doz.; 18 to 24 inches, 9/- doz.; 24 to 30 inches, 12/- to 18/- doz.; 30 to 36 inches, 18/- to 30/- doz.; cheaper by the 100.

HOLLIES, green, splendid pruned specimens, mostly furnished to the bottom, from 5 to 10 ft. high. This is a grand stock which every buyer of Hollies for ornamental grounds, screens, tall hedges, &c., should see. Prices on application.

HODGINS and other ornamental green-leaved varieties, and Silver variegated, same sizes and in equally fine plants, probably the finest stock of Hollies in the kingdom.

RETINOSPORA AUREA, Broad Pyramids, each plant a model, 12 to 18 inches, 9/- doz., 60/- 100; 18 to 24 inches, 15/- doz., £5 per 100. Cupressus and other Conifers in great variety. For List Prices and Descriptions—

DECORATIVE HELPS.

THE ever-increasing taste for the employment of cut flowers in home decorations is often a matter of some little anxiety to the provider, not to speak of occasional heavy demands entailed by floral fêtes and flower balls, which few appear to escape. That the caring hand is apt to be a sparing hand is not a matter for surprise, and any auxiliary helps to the end, provided they are as much appreciated as their more refined relatives, are worthy of consideration. Ere advancing the claims of our wildlings, however, two phases of the subject may be adverted to, the first of which is naturalisation.

When the Lilies of Lent are "a blooming," they seem to bring with them a sense of satisfaction and relief, and happy is the man who has his borders full of them; but happier still is he who has taken heed of their adaptability for naturalisation. In deep bays of the shrubberies, in the narrow margins between the grass verge and beds of shrubs where orthodoxy clings; but, above all, where freedom reigns supreme, the Daffodil is a charming object, and, what is more to our purpose, a useful one. One looks for their coming and misses their departure. For this reason, I think, they are peculiarly adapted for permanent positions, which leave no desire to oust them from it when their glory has departed. Fortunately for the decorator the Narcissus season can be well stretched by a judicious selection of varieties suitable for planting *en masse*. From such time as *N. princeps* braves blustering March till waning May winds up the procession with the chaste Gardenia-like *N. odorata* fl. pl., these charming decorative blooms play a prominent part. But, really, it is needless to laud the Lilies of Lent, the increasing abundance of which only adds to their popularity.

Tulips are equally adapted for planting out of bounds in the sunny foreground of shrubberies, and no matter how badly treated forced Tulips may be, they well repay replanting in this way. Those who do not yet know the merits of that grand late Tulip, *T. Gesneriana*, for cutting purposes, would do well to make its acquaintance.

Flowering as it does contemporaneously with the Solomon's Seal, it associates remarkably well with it in vases, the greenery of the one and the brightness of the other being both harmonious and pleasing. The Solomon's Seal is as grand for naturalisation as it is useful for cutting, and well deserves good treatment in the way of an annual top-dressing.

With the idea not only of helping the decorator, but of sparing the hardy flower borders as much as possible, many free growing plants commend themselves for treatment as wildlings, or under semi-wild culture. The *Doronicums*, *Montbretias*, many of the *Iris* tribe, *Aquilegias*, and other kinds as equally suggestive are equally useful. That hardy flowers for decorative purposes lack some of the subtle refinement which seems an inherent quality of those produced under glass goes without saying, but a good deal lays in their arrangement. As a rule, each kind goes best with its own foliage, and mixtures are seldom pleasing combinations. For instance, the big Chinese Tree *Pæonies*, cut with plenty of stem and loosely arranged in large vases, are grand objects in a large room, and *Daffodils* are never so happily displayed as when set up with their own leaves.

Garden cultivation of the most useful plants, apart from the usual routine of the hardy borders, has much to commend it for cutting purposes. The little trouble entailed in ministering to each kind's particular requirements is amply repaid by the greater quantity and higher quality of the blooms obtained. After pressing the claims of naturalisation it may appear anomalous to promulgate the doctrine of inversion—viz., the taming of our wildlings—but from the present point of view any means to the end need not be despised. The *Chrysanthemum* of our meadows, popularly called the Ox-eye or Moon Daisy, simple and common as it undoubtedly is, deserves more than a passing notice for our purpose. In old pastures poverty is often inimical to good substantial blooms, but by transferring some roots as early in the season as procurable to a well-enriched plot the beauty and usefulness of the flowers are much increased. For table decoration the Ox-eye Daisy is, in my experience, far and away the best flower of its kind. The cultivated *Marguerites* have, when cut, a disappointing habit of reflexing into nothingness. Arrangement, however, has not a little to do with the successful employment and consequent appreciation of flowers. The same also applies to all our wildlings. Over-elaboration is fatal to effect.

If we cull wildlings from the great garden of Nature, to her must we go for the secret of that nameless grace she invests them with. For a dinner-table to be successfully decorated with, say Ox-eye Daisies, they must be lavishly employed, yet loosely arranged, without any approach to primness. If the Daisies are cut full length, some with branched, others with single stem, they may, for a centrepiece, be inserted in a bowl, or other receptacle, of wet sand, care being taken to make them stand well out round the edge, disposing them *au naturel*, without any attempt at rigid formality. Whatever vases are used as supernumeraries the Daisies will be arranged in them in a similarly careless manner. Having arranged centrepiece and vases upon the table, the effect upon a white cloth is, at least, insipid, I grant you; but the one touch of Nature is yet to come; with a handful of our tall, nodding, native grasses, the missing link is restored. Given a lofty room and a large table, on which say, three or more bowls are used down the centre, such Grasses as the drooping-headed *Bromus* may be made to tower above the flowers 2 or 3 feet, making the blooms, as it were, an undergrowth.

Similar arrangements with single red Poppies or the Corncockle for a luncheon table (the colour of this is not suitable for artificial light), are particularly effective, never producing a discordant note in that harmony of natural grace in which all floral decorations should be transposed. This is but one, although the more important side of the question, the other being the saving of time and sparing of choicer materials. Beyond a boy's time spent in gathering the wildlings, an hour is ample in which to decorate a dinner-table for twenty persons. It is needless to descant at length upon the variety of material naturally supplied from such time as early summer makes the meadows and hedgerows things of beauty till late autumn crowns the year with a galaxy of dying foliage and ripening berry. Where plants are called for to furnish fireplaces during the season, the common Water Flag, *Iris pseud-acorus*, is a capital substitute. These may be cut off at the base, selecting them of whatever lengths is deemed necessary, and when placed in pickle jars of water are easily arranged *au naturel* with a bank of moss to hide the receptacles. This wildling, for the purpose, cannot be too highly recommended; not to mention its exquisite, Orchid-like, canary-yellow blossoms, which serve for other decorative purposes.

Where such things have not been hitherto introduced employers have been found to welcome the change, not less to those who grudgingly sacrifice the objects of their skill and care upon the altar of necessity.—K., *Dublin*.

HARDY FRUIT PROSPECTS IN SOUTH WALES.

NOTWITHSTANDING the severe spell of winterly weather experienced over the greater part of the country lately, and the advanced state of the fruit buds, when the thermometer registered from 18° to 30° of frost in some places, the Apple and Pear trees here are covered with strong (apparently uninjured) flower buds, which give every promise of an abundant crop of fruit, if the flowers are not injured by frost later in the season.

Last year the Apple trees bore a heavy crop, but the fruits were much smaller than usual, and a great many dropped after swelling to a good size, owing to the long continued drought, and to the young growths of the trees being badly infested with aphids and honeydew. They were so badly blighted that I was afraid they would be crippled for a year at least. I had all the points of the infected shoots cut off and burned, and the trees syringed with a mixture of softsoap and water, after which they made clean, firm, well-ripened growths bristling with fruit buds. You see, Mr. Editor, I am still a believer in having well ripened wood (whether it be the wood of Vines, Apple, or Pear trees) to produce a good crop of fruit. And, I know, I am not singular in that respect, although a writer in "our Journal" tried hard to make us believe otherwise a few years since.

The Pear trees in the open quarters never looked better. They do not seem to have been injured in the least by the long drought of last year. Pitmaston Duchess is fuller of buds than ever I remember, and the trees are going to be one mass of flowers, and the same may be said of most of the other varieties. Some trees on the walls, however, are not quite so full of flower buds this year as usual, which I attribute to the fruit borders getting so very dry during the drought of last year. Apple trees are swelling their fruit buds fast, and, like the Pear trees, promise an abundant crop if all goes well with them during the setting period of the fruit.

Plums promise well for a crop at present; the trees in a day or two will be smothered with flowers, but it is a very uncertain crop in this district. The gardens here are in close contiguity to the town—in fact, surrounded by it; and stone fruits are more subject to the attacks of aphids and red spider than trees growing in the open country districts. I have on that account given up growing Morello and other Cherries long ago, as I found it was almost impossible to keep the trees in a clean and healthy state. Try whatever remedies I might, there was no getting rid of the pests.

Peach trees in the district around Cardiff look promising, but some of the earliest opened flowers were injured by frost, although the trees were well protected by a double thickness of fish netting. Still sufficient uninjured flower buds are left to insure a crop, if the fruits set well.

CATHAYS PARK.

The fine fruit gardens in Cathays Park containing the grand collection of specimen Apples and Pear trees which have been so much admired by gardeners and others visiting the Castle Gardens, will soon be a thing of the past. Cathays Park and fruit garden (about 60 acres in all) have been sold to the Corporation for the sum of £160,000 to build a new Town Hall, Law Courts, college, museum, and other municipal buildings thereon. The Corporation have taken possession of their purchase, and thrown the park open to the public until building operations have begun. The fruit garden, for the present, is kept in their own hands, and the trees will not be done away with until the garden is required for building. I shall try, if possible, to get a few of the Apple and Pear trees photographed before they are destroyed, to keep as a memento of what can be done in fruit culture in this country in the space of twenty years.

The trees were all planted when maidens of one year's growth from the bud on free stocks. The Pear trees in the open quarters are trained as pyramids, and the Apples in tree-bush form. A great many of the Pear trees are now from 28 to 30 feet high, well furnished from base to apex, with good fruiting branches. I have never seen such fine specimen trees anywhere as those of Pitmaston Duchess, Beurré Diel, Marie Louise, Beurré d'Amanlis, Brown Beurré, Beurré Superfin, Beurré Magnifique, and Beurré Rance, as those here.

The Pear trees on the south wall are very fine; trained in fan-shape they look well at all seasons, whether denuded of leaves, covered with flowers, or bearing heavy crops of fruit. The varieties growing on the wall are Pitmaston Duchess, Beurré d'Amanlis, Easter Beurré, Williams' Bon Chrétien, Beurré Clairgeau, Beurré Diel, Marie Louise, Beurré Bosc, Beurré d'Esperne, General Todleben, and Née Plus Meuris. The wall is from 14 to 15 feet high, and it is well furnished with healthy vigorous trees from top to bottom in a full bearing state.—A PETTIGREW, *Castle Gardens, Cardiff*.

[The trees in question are highly worthy of photographic representation and preservation. When visiting Cardiff some years ago we regarded them as splendid examples of culture, training, and productiveness.]

ODONTOGLOSSUM CRISPUM DUKE OF YORK.

ON page 232, of our issue for March 23rd, we gave an illustration of *O. c. Sultan*, as being one of the finest shown at the Drill Hall on March 14th, and we now present (fig. 65) to our readers *O. c. Duke of York*, which, though entirely different in character from *Sultan*, is nevertheless superb. As the woodcut clearly conveys to the observer, the flowers are of good shape and considerable substance. The very broad petals, with their slightly wavy margins, are white, delicately flushed, and with bright red spots of varying sizes distributed over the whole surface. The narrower sepals are very similar in colour. The splendid lip has a large patch of red within the white fimbriated margin. The exhibitor was Mr. W. Stevens, gardener to W. Thompson, Esq., Walton Grange, Stone, Staffs, and a first-class certificate was recommended by the Orchid Committee of the Royal Horticultural Society.

CALANTHE WILLIAMSII.

It is very doubtful whether we need the deciduous *Calanthes* as late in the season as March, when many fine Orchids are to be had in plenty. The fine group recently arranged at the Drill Hall, however, showed their charm, and the species named above is equally beautiful. It has nearly pure white sepals and petals, with a crimson lip, and in strict botanical parlance is a variety of *C. Regneri*, from which it differs only in colour. The plant is very useful if a late display is needed, and it may be grown under the same conditions as *C. vestita*.

ODONTOGLOSSUM NEBULOSUM.

This species has been unusually fine I think during the present season, and I have noted freer-flowered plants and better form than I remember seeing before. It is a plant that does not get the attention its merits entitle it to, for it has a very distinct appearance, and is easily grown. In the type, which is far prettier than any of the varieties, the flowers are pure white on the sepals and petals, except at their base, where they are spotted with brown. Being a native of Mexico, and found at considerable altitude, the shady cool house, such as most *Odontogloss* like, is hardly to its taste. It can hardly be kept too cool, but it likes in addition ample light.

CYPRIPEDIUM SALLIERI HYEANUM.

I recently noted a fine form of this variety flowering from an importation of *C. insigne* in one of our largest London nurseries. I was rather glad to have further proof that this is a natural hybrid, for possibly some of our readers may remember the very oracular criticism in the "Orchid Review" of my notes on the subject in the *Journal of Horticulture* some two years ago. Possibly the criticism was "a feeler," for most of the people who hold such strong and certain views on these botanical questions are not above getting a hint from practical growers, who usually find out the truth of what they are writing before committing themselves.

But be this as it may, there can be no doubt—indeed, there was none before—that this *Cypripedium* occurs in a wild state. It is rather quaint to read that because *C. insigne* and *C. villosum* grow and are collected many miles apart, that therefore the possibility of a hybrid between them occurring is remote. Who that has handled a number of *C. insigne* has not noticed in many cases the villosum petals, with their lines of deeper colour on one side? I may say that in quite a number of cases it would be difficult indeed to say what the flower was, provided the upper sepal was taken off and only the lip and petals left. They are certainly more like villosum than insigne.

This question is something on a par with that as to whether or not Orchids change from year to year. Despite continued and well-authenticated evidence that they do, some authorities still hold that they do not, so presumably it is useless to try and persuade or convince them of the truth of what is so frequently noticed in our large nurseries. Personally, I had a very convincing experience many years ago, when I purchased at a rather high price a fine variety of *C. villosum aureum*, propagated it, and found the next time it bloomed that it had degenerated so much that I could not sell it as that variety.

Again, a fine variety of *Odontoglossum Pescatorei* flowered with me a few years since. The spike was cut and the plant very carefully grown in order to get all the strength possible into it. I got strength and a great branching spike with dozens of flowers upon it; still a good form, but nothing approaching to what it was originally. These are exceptional cases, but many instances of slighter alterations or deviations might be given, such as the habit of the labiata *Cattleyas* to

throw highly coloured forms one year, and the next to pale off considerably though grown under precisely similar conditions.—H. R. R.

LÆLIO-CATTLEYA ELEGANS.

THE earliest flowering plants of this beautiful family will be fast pushing their flower spikes, and should a moderate quantity be grown, they will make a charming display. The parentage has been settled, and the plants that have been raised in this country prove that Mr. Rolfe was correct when he asserted that *L.-C. elegans Schilleriana* was the result of a cross between *Lælia purpurata* and *Cattleya intermedia*, and I think we can take it for granted that all the white varieties are the result of this cross; and the very dark forms are the result of *L. purpurata* crossed *Cattleya guttata*, and its variety *Leopoldi*.

One often finds plants not growing satisfactorily, which is frequently caused by their having been grown too cool, as I find it progresses with the same treatment as *Cattleya gigas*, and if a plant were late in making its growth I should not hesitate to place it in the hottest house, of course removing it again as soon as the growths were completed. The plants delight in abundance of moisture both at the root

FIG. 65—ODONTOGLOSSUM CRISPUM DUKE OF YORK.

and in the atmosphere while in actual growth, but should never be syringed. Damp well between the pots or pans in which they are growing, twice or thrice a day, according to the outside conditions.

The compost must consist of the best fibrous peat, broken in rough lumps, with all the dust shaken out, mixed with about a third of good live sphagnum moss, and a few pieces of clean crocks to keep the whole open. The plants as well as the pots or pans in which they are growing must be kept scrupulously clean, as they are subject to the attacks of white scale and other insects, and a dirty plant cannot thrive.

Perhaps no plant shows much more variety in colour than this. From the pearly white sepalled and petalled *L.-C. elegans Stelzneriana*, to the amethyst purple *L.-C. e. Turneri*, there are various intermediate shades, the best of which are perhaps *alba* and *Schilleriana*. This plant was first found by François Devois in 1817, and flowered in Europe the following year, in the collection of the late M. Ambrose Verschaffelt of Ghent; since then small importations have reached this country from time to time.—J. BARKER, *Hessle*.

PINUS RIGIDA.—In regard to the name of *rigida*, the Rigid Pine, given to this species, Mr. C. F. Saunders, describing a visit in winter to the Pine Barrens of New Jersey, says in "Meehan's Monthly"—"In the white light of a January dawn, we rally forth down a frozen road of sand into the Pines. Covered with their tufted green needles, the trees stretch away on every hand in long avenues of restfulness, with bushy seedlings, like little toddling children, clinging about their feet. These are principally Pitch Pines—*Pinus rigida*—literally the Rigid Pine. How well named rigid one sees as he notices their action before a high wind. Where the White Pines would bend gracefully and toss their branches with an elastic motion, these Rigid Pines doggedly jerk backward and forward, their trunks stiff as ramrods from top to bottom, and as graceless, every branch tense and unyielding. The resistless blast forces them aside as it rushes along, but it cannot make them bow.

NOTES ON PALMS.

SOME of the popular species and varieties of these indispensable plants seem to possess the power of adapting themselves to widely different cultural treatment, for they will endure a great amount of ill-usage, not, perhaps, with impunity, but still without being killed outright. They revel in the highest temperature kept up in any hot-house as long as the atmosphere is well charged with moisture, and a few months' sojourn in a cool house in winter leaves little if any permanent effect on them, only simply retards growth for a time.

In regard to soils their adaptability is quite as great. Importations from the Continent may frequently be seen growing luxuriantly in pure leaf soil; and in this country grand specimens may be met with which have been potted in nothing but stiff loam. Between these two extremes there is usually a "golden mean" which is safe to follow, as it gives satisfactory results. A certain amount of experience is necessary in testing the soil one has at command before it is safe to use loam alone for Palms. In some districts, where free fibrous mellow loam can readily be obtained, I have found both Palms and Crotons succeed splendidly in it with no other addition than that of a little burnt refuse. In other localities—especially where the loam rests on clay—great caution is necessary in employing it exclusively for such plants, as they do not root in it readily, although they succeed fairly well when once established. Loam of this description, although it may contain a fair amount of fibre, does not possess that friable nature which cultivators like to see. When dry it is hard and lumpy. When soil of this description must perforce be used, an equal quantity of good fibrous peat and a liberal addition of sharp sand mixed with it, form a safe compost to use. Those who successfully employ heavy loam for growing Palms in are fortunately placed in being able to secure a sample which has peculiar characteristics, for although heavy its component parts are thoroughly blended, the sand and the clay being evenly distributed throughout in the right proportion to make the soil holding, yet not lumpy. In a loam of this type Kentias, Latantias, and Phoenix succeed admirably.

I remember about twenty years ago, when working in one of the great London nurseries where Palms were extensively grown, the regulation compost for Palms was peat and rather light fibrous loam in equal parts. The son of a continental nurseryman was spending some months in the nursery in order to note English methods of business and cultural practices. His idea was that our Palm compost was far too light, but the departmental foreman usually managed "to take the wind out of his sails" by pointing to the grand stock of plants of various sizes in the houses, which the precise German was bound to admit he had never seen surpassed. After having tried composts of various descriptions for *Cocos Weddelliana* I have formed the opinion that fibrous brown peat, with sand and charcoal added, is generally the most suitable soil to employ for this very graceful yet fastidious Palm. In a young state they never seem to thrive satisfactorily unless plunged in some material having a nice bottom heat, as so few roots are formed during the first six months of the plant's existence. I make a practice of transferring young plants from "thimbles" to 3½-inch pots, and then plunge again in bottom heat till roots are plentiful in the new soil. After this stage is reached the plants thrive well on an ordinary stage in a stove or forcing house. Healthy *Cocos* will bear a considerable amount of sunshine, and when shading is reduced to a minimum the fronds possess great substance.

In the case of all Palms firm potting should be practised, they then assume a good habit of growth and roots permeate the soil evenly. When repotting strong growing Palms which have forced the ball above the rim of the pot very little drainage should be used, as it is important to get them low enough in the new pots to allow space for holding water after the old ball has been covered with half an inch of soil. For 8 and 9-inch pots I have frequently employed only one large crock, this being covered with moss, and have never found that amount of drainage insufficient when careful watering was practised. Plants which have forced themselves upward in the pot invariably have a mass of strong roots at the base which form efficient drainage, as well as give vigour to growth, and it is a barbarous practice to cut such roots away to enable the plant to be lowered in the pot, and at the same time give the regulation amount of drainage.

Plenty of heat and abundance of atmospheric moisture are essential conditions to observe in Palm growing, but the practice of syringing regularly at fixed times, independent of weather, is not a good one. During dull weather the moisture ought to be applied by damping walls and stages and filling evaporating pans, syringing occasionally when the hot-water pipes become overheated, and regularly during bright weather. The midday syringing in summer time is of immense advantage, as when the house is at its highest temperature is just the time for a saturated condition of the atmosphere, yet the practice is not followed as generally as it should be.

Regularly dipping the plants in an insecticide solution helps to keep insects in check, but I have not yet been able to kill brown or

white scale with any of the advertised insecticides when used according to the directions given unless the plants are dipped while the insects are in a very young stage. Although insecticides have to a great extent done away with the tedious work of hand sponging, it is not wise to dispense with the latter operation altogether, as when well done it leaves the fronds beautifully clean and fresh, and the plants seem to thrive the better for it.—H. D.

EXPERIMENTAL HORTICULTURE.—I.

EXPERIMENT is a comprehensive term, as, though it is commonly defined as an undertaking directed to proving or disproving something already accepted or questioned, it may include every practical operation of which the result is not an absolute certainty. It may be a duly organised and intentional search for knowledge, or it may be only an accidental trial, yet in a broad sense both are experimental, though the utility of the latter may be greatly reduced from want of system. The scope of experimental work is very wide, and the demand for such research is a necessity of the times. There is an enormous and increasing competition to face with producers in other nations, and every process or method requires the closest examination or testing with a view to possible improvement.

British horticulturists deservedly occupy a foremost position as skilful cultivators, the thousands of admirably kept public and private gardens throughout the kingdom, together with the numerous exhibitions, afford ample testimony of this fact. No other country has produced so many triumphs of practical skill as the United Kingdom, yet the most experienced men will be ready to admit that even in their daily work, after, perhaps, half a century's study and practice, difficulties are constantly cropping up that are most perplexing, and which could only be solved by careful experiment.

Instances innumerable must be known to all, but a few will be mentioned which come within my own knowledge. An able gardener had charge of a place where hardy fruits were greatly prized, and there he excelled in the culture of Pears; the trees were pictures of health, they produced liberal crops of magnificent fruits; the pride of the employer and the envy of his neighbours. Over a course of years failure was unknown, and the fame of the gardener was established as a most successful cultivator. Some alteration in the establishment at last compelled the gardener to take another appointment, which he found in the same district and a short distance from the scene of his former triumphs. Pears were naturally again the object of his attention; old trees were treated and young ones planted, and the results which had hitherto attended his efforts were expected, but they did not come. The trees made poor growth, the leaves were imperfectly developed, little fruit was formed, and that often cracked or defective, everything being as unsatisfactory as it well could be. So it has continued year after year; all efforts have failed to produce the desired results; manures of many kinds have been tried, lifting, replanting, and all means that an experienced man can employ to accomplish the purpose in view. Failure of a most marked character is the only result, and now a friend writes to say that he believes these refractory Pears will send poor Mr. X. out of his mind, because he takes the matter so much to heart.

Another example of the difficulties horticulturists have to encounter is afforded by a certain establishment where, for a considerable time, strenuous efforts have been made to grow Vines that would produce Grapes fit for table. Within recent years no less than four gardeners, skilled men who have produced satisfactory Grapes elsewhere, have tried to accomplish this task, and successively failed, in precisely the same way, notwithstanding new borders and fresh plants. Up to a certain stage the Vines would flourish amazingly, then they would suddenly cease developing, and the fruit would shank to a disastrous extent. Such experiences come within the scope of many practitioners, and even market growers do not escape, for I know men whose losses would have to be reckoned by thousands of pounds, and yet all their skill, experience, and abundant pecuniary means have failed to enable them to effectually prevent such losses or to combat the difficulties successfully when they come.

Even amongst vegetables you have all known instances where success in one place has been followed by failure in another or *vice versa*, and I remember some years ago an example in the case of an excellent variety of Pea which in the same hands was a remarkable success in one place and as great a repeated failure in another. With some plants under glass similar results are frequently experienced, and especially is this the case with certain Orchids, of which abundant examples could be given; but what has been said will be enough to illustrate the point to which I wished to draw attention—namely, that with all the skill employed in British horticulture and the successful results generally, there is still much that demands research, and it is there that experimental work can perform a useful service. In the great subject of manures alone there is ample room for most useful work that would be of service to thousands.

FOREIGN EXPERIMENTAL WORK.

The necessity for such work in connection with agriculture has long been recognised, and in some cases horticulture is now included. In the United States of America an excellent system has been developed, chiefly at the national expense. No less than fifty-five experimental stations are now in operation there, in the majority of which are departments for agricultural and horticultural research, and reports of the work done are prepared for general distribution. Then there is a head-quarters, the office of experiment stations, under the direction of Dr. A. C. True, and there a digest is produced of all the work, and issued monthly in the *Experimental Station Record*. One of the recent annual volumes of this useful work comprises over 1000 pages, giving abstracts of 267 bulletins and forty-three annual reports, besides 227 abstracts of reports from foreign investigations, special articles of importance by foreign workers being translated and published entire in the *Record*. The whole of the information is most laboriously classified and indexed, so that it is readily accessible to all. Besides this the *Record* is distributed gratuitously to workers both in the United States and elsewhere, the nation defraying the postage. Our American cousins believe in doing things on a colossal scale, and certainly their organisation in connection with experimental work is highly creditable to them as a nation and an example for the whole world.

After an examination of the stations the Secretary of Agriculture reported as follows:—"In a general way it may be said that the investigation of the work clearly indicates that even the poorest of our stations have done scientific work of practical benefit to their communities, and that in many cases the services the stations have already rendered have been of great value, far surpassing in the aggregate the total amount of expenditure made for them by the National Government. The greatest hindrances to successful work have arisen in those communities which have failed to appreciate the fact that the stations are primarily scientific institutions, and that while they should always keep steadily in view the practical results to be obtained, they render the most permanent benefits when they make thorough scientific investigations of problems underlying successful agriculture and horticulture." In concluding, the same writer draws attention to a matter of great consequence. "The importance of adopting definite lines of work and sticking to them until definite results have been obtained is strongly urged."

I will next refer to experimental stations in Germany, France, and Britain.—R. LEWIS CASTLE.

CULTURE OF ADIANTUM CUNEATUM.

Few, if any, Ferns enjoy more popularity than the Maidenhair (*Adiantum cuneatum*). It is a Fern which is easily grown, and succeeds in structures of different temperatures, though it grows best and makes the finest specimens in a stove or intermediate temperature. It grows well in a greenhouse in summer, and lasts well throughout the autumn and winter, but as a rule the plants are shabby in spring, and late in starting into growth. The system of culture adapted for a stove could not be carried out with the greenhouse plants, because it would be too early to divide and repot plants to be grown. However, the compost, method of dividing and repotting, shading, and watering, are the same, but carried out at different periods. Stove plants may be repotted, divided, and potted or shifted from small pots into larger, as early as February. In an intermediate temperature March is early enough, while for those grown in a greenhouse April will be more suitable.

Before commencing to pot these Ferns it is highly desirable that clean dry pots be in readiness, and compost of a turfy open character employed. A mixture of turfy peat and turfy loam in equal parts, with a free admixture of leaf soil, sand, and charcoal forms admirable potting material for all sizes of plants. Small thrifty plants in 3-inch pots may be moved into 5-inch pots. Good plants in 5-inch pots ought to have a shift into 7 or 8-inch pots. Plants ready for a move from the latter sizes will require 10-inch pots. If still larger specimens are required another shift may be made into 14-inch pots.

Large old plants which have not been repotted for years ought to be turned out of their pots, the roots cut through just above the drainage, and then be divided into two or four, then reduce the divisions until they can be comfortably placed in pots of suitable size to accommodate them, and a fair quantity of compost round the roots, neither overpotting nor underpotting. In the former case the soil will be soured before roots can occupy it, and in the latter vigorous growth will not be encouraged. The pots should be carefully crocked, and some rough parts of the compost placed over the crocks to exclude soil from the drainage. Make the compost fairly firm round the roots, finishing off so that the crowns from which the fronds spring are level with the surface of the soil.

A moist, warm atmosphere is best for the plants after potting, for under such conditions little water will be required at the roots until they have freely pushed afresh into the new compost. Excessive

light will be trying to the plants; not only so, but hot sunshine dries up the soil, rendering frequent watering necessary. Shade will, therefore, be beneficial, but it is desirable to afford it judiciously. Heavy and continuous shade causes the fronds to develop a dark green hue, but they are much deficient in lasting qualities, soon withering when cut. Plants grown under light conditions possess more substance, though they are of a less dense green. Affording rather heavy shade at first is without doubt beneficial, but afterwards all the light the plants will endure and a good circulation of air produce the best results. The pots ought always to stand on a moist base, which tends to equalise the atmosphere about the plants.

Water will be needed in increasing quantity as growth advances. When the pots are full of roots weak soot water given occasionally is of assistance. Syringing is not needed so much by the plants, but the humid atmosphere it creates is decidedly helpful in promoting growth. The sides of the pots, the material on which they stand, the walls, staging, and other available surfaces may be regularly moistened in hot weather with advantage.

When growth has been completed, quite cool and airy conditions suit the plants, which maintain a healthy appearance throughout the autumn if fronds are not too freely cut. Plants well grown from spores usually produce in due time finer fronds than those which result from clusters of weak divided crowns.—E. D. S.

SOUGHT AND FOUND.

(Continued from page 212.)

"DRAINER?" It appears to me that ever since this place was breached the sewage and liquid manure have been allowed to escape to the river through the agency of that filthy orchard ditch. Now, I want to treat with you for the utilisation of sewage apart from night soil. To do so we must first lay an underground drain to lead from the farmyard; next, a like conveyance from the back kitchen sink, not forgetting an "odour trap" insertion for the latter; and lastly, a drain leading from the cemented sewage tank. As there is a gentle incline to lead into the orchard, 3-inch diameter iron pipes can be inserted to convey the liquid into a network of shallow open drains cut in the turf, and by its own specific gravity be conveyed to any part, or tree, in the orchard, or any other place where it might be required. These things were done; the results answered, and are adhered to to this day, and more, the tiled buildings were furnished with gutters, and nothing but the rain-water caught from them and those from the house is allowed to escape down the ditch into the river from these premises.

"*Editeurs obligés.*" I haven't done with my tale of the waters yet. In a yard recess at Rushbrooke Hall, in Suffolk, an old Elizabethan mansion, near to where stood a force-pump, when a stripling of ten, or thereabouts, it was my allotted task through its agency to keep a special cistern supplied with water. Alas! gaping cistern, with tap drawn dry, and a too frequent wrathful kitchenmaid. In the centre of the yard, however, there happened to be just then a hollow into and out of which to jump was more fascinating than to pump, till one eventful day, when I was exercising my bounding abilities, and had alighted on to the opposite brink, down went the flagged sinkage into a deep, gaping well; and my jump but just saved me from a jumble amongst decayed timber and stone and goodness knows how many feet of water—a fearful chasm. I related the above circumstance to the "Drainer" as a reason for what I wanted him to find, adding, I think I can observe a sinking going on here in the Walnut tree yard, and I don't want a repetition of what happened at Rushbrooke. Let us know the reason of this sinkage. Dig away, but do not stand on the opening of rotten timber slabs that had given way and were resting on *débris* of earth and very old patterned well-brieks. Now the question, Did you ever work at well-sinking? "Yes, many a one." Then if you can sink a well you certainly can empty one that has been filled up; this may prove to be merely a shallow dry one, but we shall see.

Soon Tillen alone found himself insufficient. Wooff was called in to assist, and when both were unequal to the work, the latter's son was added; then, to the rescue, I was included. As water trickled in it was necessary to be quick, and not until a depth of 40 feet was obtained did we reach the bottom of the bricks resting upon the blue clay. "Shall we go down any further," said Tillen. "No, if water comes, of which there seems every probability, I do not know that we shall want it. It might be no one knows how far before we got through the clay down to the chalk! The old fellows who sank the well in every probability knew what they were about, but we shall never know why it was filled in; at any rate, we are recompensed with sufficient soil to top-dress the home meadow. You know how to remove your staging paraphernalia, and how to rectify the brick-work, Tillen, and then we will leave well alone."

Result: I was happy to find no accident occurred, for "drainer" twisted himself about like an eel, and now and ever since some 20 feet depth of water, a little more or less according to the seasons, presents

itself. It is "clear as crystal," "hard as iron," and "cold as charity;" but it has been the delight of the missus in hot summer weather, when the butter "run," for then, by some cloth envelope arrangement, it is entered into a bucket, which by the aid of a long chain is sunk to the bottom of the well, to be again withdrawn in the course of an hour's time firm and fit for "making up." Our spring water is so charmingly soft that we never want the well water for the household. Hard water is best for brewing with. I used it here for two years, till the American Apples spoilt my Reading market; but now, excepting those the missus requires for home supply, and a good village request, I make the rest into cider and save my brewer's bill, and the sewage supply that the trees get secures and maintains for us good crops of fruit, plus the fowls, for ever since we came here the orchard has been the "chicken" run. Albeit, this makes us look out for the fallen fruit, more particularly those of the first to escape from the trees—the grub containers; at least, that is when the cocks and hens allow us the chance, for they quickly run, or rather fly, to the spot directly they hear the concussion with mother earth, and then unfortunate Apple, woe be to the maggot—no cider, no moth to follow from you.

Well, I felt as I read friend Pownall, on page 209, of what encouragement the lecturers and illustrators receive from the county councillors in his latitudes. How I should like to live in a recognised position! My first orchard that I planted, to set an example to follow on, was in 1837, and my first treatise on "Planting" was published in the pages of the *Cottage Gardener* in 1851. I have been "at" this sort of thing ever since, and now this place is completed as a grown-up lecture—thoroughly drained, the arable land laid, if down to grass now become well "knitted," fruit, forest, and ornamental trees planted now grown up and growing into production; a model of what a small residential property or cottage farm should be. But—I have never been able to "catch the Speaker's eye"—to receive the slightest County Council encouragement, or a pat on the back from any high authority in the way of rendering the slightest assistance; all done single-handed. *Si sic gloria omnes.*—ROBT. FENN, *Sulhamstead, near Reading.*

A TRANSFORMATION.

I WAS pleased to see that your correspondent, Mr. Geo. Picker, has drawn attention (page 240) to the neglected state of many of our fruit trees, in allowing them to be covered with moss, lichen, scale, American blight, and red spider. Three years ago I heard a lecture on fruit culture by Mr. E. Molyneux, who also showed samples of Apple and Pear trees dressed with caustic soda and pearlash. In March, 1896, I ordered a Vermorel knapsack sprayer with the extra 8 feet of rubber hose and the 16-foot telescope brass rod with the three different sized nozzles. I had some difficulty in getting the potash, as I wanted a special make—viz, Greenbank's X, 98 per cent. When my dressing was ready the leaves were fast expanding, so I could only apply the mixture to the trunks of the trees and to a few feet of their branches. I used about 350 gallons of the liquid that season, and so effectual was it, that this month, March, 1899, I can tell to an inch where the dressing was applied. It seems to have destroyed the outside of the bark, which has dried up and fallen, leaving the tree stem bright and green. This year I have done more with it, having used $\frac{3}{4}$ cwt. caustic soda and $\frac{3}{4}$ cwt. pearlash, which made 825 gallons of mixture. With this I dressed over 2000 trees, varying in size from 3 to 35 feet high, and from 3 to 40 inches diameter. With the Vermorel sprayer, and using the medium-sized nozzle, a grand spray is secured, so much so, that people watching the work said we were smoking the trees.

It is a very lively time for all insects. Scale I have seen fall from the tree on the slightest touch ten minutes after dressing. Workmen on this job should wear their oldest clothes and boots. To protect the hands use rubber gloves, such as are used by doctors for post-mortems. At the end of the glove bind round the wrist a piece of cloth to prevent the solution running down the arm when working with the arms above the head. I also guarded my face with a bee-veil, which must be washed every night, or the potash will dry and fly off in a powder and get into your nose and throat, which is very unpleasant.

In mixing I dissolve 5 lbs. pearlash in hot water and 5 lbs. caustic soda with boiling water. Great care is required in dissolving the soda, as it boils over if too much water is added at a time. With these quantities I make 50 gallons of solution. I should certainly have tried the softsoap had I known of it, and will bear it in mind another year. I see on page 230, under "Orchard Spraying in Nova Scotia"—potash spray: that $\frac{1}{2}$ lb. to 1 lb. of crude caustic potash is used to the gallon of water. Would not this be too strong for, say, last year's growth of our fruit trees? I should like also to ask the same correspondent if he can name the best thing to rub on the hands and face before using the above? I see for Bordeaux mixture he recommends mutton fat. Before using a veil my face was burnt all over by the falling spray.

Any hints to prevent injury to users of the spray will be thankfully received. Of course, by the use of a veil, the sight is obstructed. It is time wasted to use old chemicals. I used some, left over, three years ago, with little effect. The trees so dressed will have to be done again next year.—JNO. MILES, *Southampton.*

SOME OLD-FASHIONED PLANTS.

IN out of the way places one finds some of our old favourites still grown, cherished perhaps for old association's sake, or for the merits inherent in themselves, but which in these days of growing for cut flowers have in many instances become neglected. The plants of which I intend to mention are really useful for the embellishment of the greenhouse or conservatory, though their flowers may not be of much value in a cut state.

Libonia floribunda.—How handsome are well-grown specimens of *Libonia floribunda*. When I observe them grouped amongst *Callas*, *Eupatoriums*, and *Azaleas*, I cannot help wishing they were oftener seen. They are easy to propagate, easy to grow, and it may well be added easy to spoil. Cuttings of young growths root readily in a frame on a hoibed at any time when procurable, though spring is perhaps the best. When rooted the young plants should be placed in 3-inch pots, in a compost consisting of sandy loam and leaf mould, and kept in a close frame for a time, be repotted as soon as the roots reach the sides of the pots, and placed back in the frame until the roots take to the new soil, when the plants may be gradually hardened and stood out of doors on a bed of coal ashes until the approach of bad weather. A fairly warm light greenhouse suits them best in the winter. Plants in 6-inch pots are generally large enough; afterwards an annual slight reduction of the ball and a return to the same size of pot with fresh soil will keep them in health for some years. Care is necessary to supply abundance of water when the pots are full of roots, as neglect of this will often cause the leaves to fall, thus rendering the plants unsightly, and at the same time cause an absence of flowers.

Streptosolon Jamesoni.—Efforts have once or twice been made to popularise this old friend, but so far it is rarely grown. Its rather straggling habit militates against its becoming a general favourite. The colour of the flowers should recommend it however, being, under good cultivation, a deep reddish orange. The cultural conditions accorded *Libonias* apply equally well to this plant, with the addition of a few stakes, as it requires tying into shape.

Mimulus (Diplacus) glutinosus.—Why this is not more often grown for house decoration in small pots it is difficult to understand. The blooms are not only of a beautiful colour, but are also quaintly shaped, and ladies readily fall in love with them. It stands and keeps fresh in rooms a long time, when receiving due care. After our plants have finished flowering we usually insert a few cuttings in a close frame. A rather light sandy soil suits the plants best, with ordinary greenhouse treatment. The leaves are, as the name implies, sticky, and not pleasant to handle.

Scented "*Geraniums*."—How often in cottage homes have these given pleasure? They are also useful for the greenhouse, and a few sprays mixed with cut flowers are at times greatly appreciated. Cuttings of clean healthy growth, inserted in sandy soil in spring, and placed in a warm corner, soon root, and may be quickly grown into fair sized plants. The old oak leaved, the peppermint scented, the lemon scented, and the variegated Lady Plymouth, are all of easy growth.

Primula alba p'ena.—Since the introduction of the semi-double varieties of *Primula sinensis*, this useful plant has fallen somewhat out of cultivation. This is rather to be deplored, as of all the indoor *Primulas* this is, I think, the most beautiful. It is at times a cause of slight trouble in propagating, but if the lower parts of the young growths are mounded up with some light sandy soil, consisting chiefly of leaf mould, roots will soon be emitted if the mulching round the collar be kept moist. When this has taken place they should be severed from the parent plant with a sharp knife, potted into small pots and be kept close on a hoibed until growth has well commenced. Afterwards they may be hardened and placed with the other plants which are being grown in cold frames. This plant repays for rather a higher temperature than is usually accorded *Primulas* in the winter, and also responds to liberal treatment in the matter of feeding.

Crassula (Kulosanthes) coccinea.—Of very little or no use for cutting is this old occupant of our glass houses. It may be charged with being of a stiff and rather ungainly habit, yet the deep rich green of the leaves, and the bright, sweet-scented flower-heads, have a beauty all their own, and room may well be found for a few plants where possible. Cuttings should be rooted annually, three or four in a 3 inch pot, as these kept through the winter and repotted in spring make good plants. Care is necessary during the dark dull days in the matter of watering, otherwise the culture is of the easiest.

Begonia metallica.—This is not quite such an ancient occupant of our gardens as some of those already mentioned, but has been known sufficiently long to be included under the heading. A rather higher temperature than the ordinary greenhouse is most suitable, but it will grow and make a useful plant in cool quarters if care is taken with watering. Cuttings inserted singly in thumb pots, or three or four in larger ones, placed in heat, soon grow and make useful stock. The flowers in themselves are pretty, if of no use in vases, and add considerably to the beauty of the plant.

I could enumerate many more, such as *Rhynchospermum jasminoides*, a favourite inmate of our glass houses; *Linum trigynum*, with its lovely yellow flowers, which drop all too quickly, but if the plants are grown strongly and bloomed in a cool house the trouble is lessened in a great measure; also some of the old climbers, such as *Tecoma jasminoides* and *Abutilon vexillarium*, amongst many others. But I must stop, such hosts of recollections and memories arise as I write of these old-time favourites that I fear my pen may stray to some divergent theme.—J. SHALFORD.

RECENT WEATHER IN LONDON.—Holiday makers around London will have rejoiced in the pleasant weather that prevailed from Saturday until Monday night. True, rain threatened to fall several times, but only came in very brief drizzles. On Tuesday morning, and again after noon, there were several rather heavy showers. At the time of going to press on Wednesday it was warm and summer-like.

— WEATHER IN THE NORTH.—A good deal of rain has fallen during the week ending 3rd inst., and high winds have been frequent, with a much higher temperature. Snow fell heavily on the morning of Saturday, giving place to rain in the afternoon. This continued throughout Sunday and Monday morning, but the afternoon was pleasant with a light wind from the west.—B. D., *S. Perthshire*.

— MISTLETOE PROPAGATION BY BIRDS.—Looking around the gardens and new conservatory at Merlin, near this town, recently with Mr. and Mrs. Fayle, we were shown on an Apple tree a young Mistletoe seedling growing through bird excrement, showing the seed and berries must have been eaten in the winter by blackbirds or thrushes, and voided by them intact on the Apple bough, and then commenced to grow as a parasite from the Apple bark. This system of seed propagation in unlikely places is not unusual.—W. J. MURPHY, *Clonmel*.

— ANCIENT SOCIETY OF YORK FLORISTS.—The rules and schedules of prizes to be held in connection with this excellent Society during the present year have come to hand, and it is evident that there is to be no retrogression. The total amount in prize money reaches upwards of £400, distributed over numerous classes at several exhibitions, of which the chief appears to be the Chrysanthemum on November 15th, 16th, and 17th in the Exhibition Buildings of York. The book embodies also the names of the patrons and officials, together with a list of the subscribing members. Mr. Geo. F. W. Oman, 38, Petergate, York, assumes the office of Secretary, in succession to Mr. J. Lazenby, who has retired.

— PRESENTATION TO MR. JOHN LAZENBY.—At a meeting held on Thursday last, the Committee of the Ancient Society of York Florists presented to Mr. John Lazenby, who has resigned the post of Secretary, an illuminated testimonial and a purse of gold, subscribed for by members of the Society and other friends. Mr. J. C. Milburn took the chair. Mr. J. Pillmoor made the presentation, and expressed the regret of the President (Alderman McKay) that he was unable to attend. Councillor Staines said there was no doubt the members of the Society had regretted and would continue to regret, that their late Secretary's ill health had brought about his resignation; at the same time they hoped he would still be able to help forward the good work in connection with which he had done so much during his twenty years of service. Mr. Lazenby thanked the promoters and the subscribers to the testimonial, and said that since he had given up the responsibility of the office he had had better health.

— THE NASH.—On the occasion of a recent call at The Nash Kempsey, Worcester, the picturesque old home of Sir Richard Temple, Bart., I was much interested in a very fine display of Cinerarias and Cyclamens in a lean-to house facing the flower garden in front of the mansion. The central stage was completely filled with magnificent Cinerarias, the pots being hidden by luxuriant foliage. The habit of the plants was excellent, and the colour, form, and size of flowers superb. But perhaps even more noteworthy were the 200 Cyclamens which filled the front stages. All shades, from the purest white to the richest crimson, were splendidly represented. The various colours were grouped, and in this way comparison was simplified. As I saw them they were literally a mass of flower, the pots being covered by the handsome foliage. The plants were seedlings flowering for the first time, and started throwing up flowers in September. During the summer months they were kept growing, plunged in cold frames well up to the glass, constantly moistened with the syringe, and lightly shaded during bright sunshine. The compost used for them was little else but good fibrous loam, coarse leaf soil, and sand. Altogether Mr. Justice has every reason to be proud of the display. A feature on the kitchen garden walls is a collection of well trained young Peach trees, many of which carried good crops of fine fruit last season.—W. H. W.

— DEATH OF MONS. CHARLES NAUDIN.—We regret to learn from the "Gardeners' Chronicle" of the death, on the 19th ult., of this most celebrated French horticulturist. The deceased was eighty-three years of age, and has long been Director of the Villa Thuret, at Antibes. He was a botanist of the first order, and his loss will not be that of France alone, but of the whole gardening world.

— GARDENING APPOINTMENTS.—Mr. Mossop, several years gardener at Blawith, Grange-over-Sands, has been appointed head gardener to Harvey Goodwin, Esq., Orton Hall, Westmoreland. Mr. Arthur Childs, four years foreman at Sedgwick House, Kendal, has gone as gardener to B. Mitchell Innes, Esq., Churchill, Hemel Hempstead. Mr. W. Meredith, seven years with D. P. Seller, Esq., Dudbrook House, Brentwood, Essex, has been appointed to Stansted Park, Emsworth, Sussex.

— HAWFINCHES AND PEAS.—We have, I am sorry to say, suffered considerable loss from these birds in the past. With the exception of their weakness for Peas, I have not heard that there is any other wickedness known about these beautiful creatures. In some districts they may be numerous, but so far as I know they are comparatively rare, and that is one reason why they were not mentioned in my notes on Peas. As soon as we perceive signs of their presence we dust all over the rows of Peas with lime; it is of course best done after a shower, or in early morning when the dew is on. This has proved effectual, and saved us many dishes of Peas. Early rows appear to be exempt from their attacks.—J. SHALFORD.

— CROCUSES AT HAMPTON COURT.—The Superintendent of the Palace Gardens is to be congratulated on having created for the delectation of the thousands of visitors who attend this attractive place of resort at Easter quite a floral sensation with Dutch Crocuses only. These early flowering bulbs are not seen in long formal lines, neither are they in solid clumps or massed in beds. They are dotted on to the broad grass glade that runs between the upper range of flower beds and the moat, and beneath the tall rows of Limes. They are in informal masses, yet not in dense masses. In some cases two or three colours are mixed, in others are of one variety. The space covered extends from the garden entrance to the Hampton Road, is very broad, and probably some 300 yards in length. As a display of Crocuses, it is without exception one of the prettiest yet seen.—D.

— WAKEFIELD PAXTON SOCIETY.—Programme of meetings for the first quarter—session 1899. Meetings are held each Saturday evening at eight o'clock. April 1st, "Gardeners," Mr. J. L. Twigge, Wakefield. April 8th, "Orchids for Beginners," Mr. John T. Barker, Hessele. April 15th, "Daffodils," Mr. W. Garside, Wakefield. April 22nd, "Some Plant Parasites and Messmates," Mr. F. Rhodes, Bradford. April 29th, "Spring Flowering Bulbs and Alpines," Mr. W. A. Clark, Messrs. J. Backhouse & Son's Nurseries, York. May 6th, "The Cultivation of the Peach and Nectarine," Mr. Geo. Hudson, Woolley. May 13th, "Practical Poultry Breeding and Rearing," illustrated, Mr. W. E. Corden, Wakefield. May 20th, "The Gloxinia," Mr. T. Gartery, Rotherham. May 27th, "Principles of Botanical Classification," Mr. J. W. D. McPherson, B.A., Grammar School, Wakefield.—T. H. MOUNTAIN, A.S. NICHOLSON, *Hon. Secs.*

— ISLE OF WIGHT.—The Isle of Wight Horticultural Improvement Association held its third annual non-competitive exhibition of Daffodils and spring flowers at Ventnor on Saturday, April 1st. The Show was opened by Dr. J. Groves, who said the Association had been formed to encourage the development of horticulture in the island so as to give pleasure and provide for the wants of the many visitors, on whom they (the islanders) were largely dependent for their livelihood. The show was scarcely up to its usual standard, though there were some excellent flowers staged by Messrs. Barr & Sons of London. Mr. Geo. Honeybourne, gardener to Lady Daly of Ryde, staged a fine collection of Daffodils, and received the Association certificate for cultural merit. Mr. W. W. Sheath, gardener to Miss Mitchell of Ventnor, arranged a group of miscellaneous flowering and foliage plants, including some fine specimen *Primula obconica* and *Euphorbia splendens*. Mr. W. Russell, gardener to C. H. Comb, Esq., Bonchurch, sent a group of flowering and foliage plants in addition to a fine collection of Narcissi. Mr. F. A. Hill, gardener to Miss Cass of Ventnor, contributed some *Spiraea japonica*, and Mr. A. J. Cole, gardener to — Rendell, Esq., of Sandown, a nicely arranged vase of Sir Watkin, which was much appreciated. The Association is also encouraging bee-keeping, and Mr. W. S. Barnes' observatory hive and section honey were a great attraction. Mr. C. Smith of Ventnor, an amateur, well merited the Association certificate for cultural merit for a large and well grown plant of *Imantophyllum miniatum*.

The week ending April 1st has been very mild and spring-like, with a remarkable absence of sun.

— MARCH WEATHER AT HODSOCK PRIORY.—Mean temperature, 41.5°, + 0.7°. Maximum in the screen, 62.2°, on the 11th; minimum in the screen, 16.7°, on the 22nd. Minimum on the grass, 1.1°, on the 22nd. Frosts, in the shade, 16; on the grass, 24. Sunshine, 120 hours, or 33 per cent. of the possible duration; difference from average, + 14. Rainfall, 0.83 inches; difference from average, - 0.82. Rainy days, thirteen. Maximum fall, 30 inches, on the 30th. Rainfall from January 1st, 4.20 inches; difference from average, - 0.91. A dry and fairly bright month, with a very sharp spell of cold in the third week.—J. MALLENDER.

— MARCH WEATHER AT BELVOIR CASTLE.—The prevailing direction of the wind was west on twenty-three days. The total rainfall was 0.59 inch, which fell on ten days, and is 0.97 inch below the average for the month; the greatest daily fall was 0.20 inch on the 30th. Barometer (corrected and reduced), highest reading, 30.628 inches, on the 1st, at 9 A.M.; lowest, 29.035 inches, on the 9th, at 9 A.M. Thermometers, highest in the shade, 59°, on the 11th; lowest, 15°, on the 21st. Mean of daily maxima, 48.80°; mean of daily minima, 31.25°. Mean temperature of the month, 40.02°; lowest on the grass, 12°, on the 21st; highest in the sun, 110°, on the 12th. Mean temperature of the earth 3 feet deep, 40.83°. Total sunshine, 175 hours 40 minutes. There were two sunless days.—W. H. DIVERS.

— SUSSEX WEATHER.—The total rainfall for the past month at Stonehurst, Aidingly, was 1.00 inch, being 1.08 inch below the average. The heaviest fall was 0.49 inch on the 25th. Rain fell on six days. The total fall for the quarter was 7.44 inches, which is 0.78 inch above the normal. The maximum temperature was 59° on the 30th, the minimum 20° on the 21st and 22nd. Mean maximum, 49.17°; mean minimum, 32.19°. Mean temperature 40.68°, which is slightly below the average. The minimum temperatures from the 19th to the 25th were 27°, 25°, 20°, 20°, 21°, 22°, 26°. On the evening of the 21st there was thunder and lightning, and in a very short time everything was covered with 2 inches of snow, which lay till the sun melted it next day. The frost has blackened all Peach bloom that was expanded, though covered with two thicknesses of mats. Early Pear bloom has also suffered.—R. I.

— GIGANTIC SPEAR LILY OF AUSTRALIA.—The Gigantic Spear Lily (*Doryanthes excelsa*) of New South Wales is much rarer in our gardens than its singular beauty entitles it to be, says an Australian exchange. In early summer visitors to the Illawarra district are attracted by straight stems, 20 feet high, surmounted by bulky flower-heads of a deep crimson colour. The flowers are Lily-like, each petal being about 5 inches in length; they open in succession, so that for many weeks the plants remain in blossom. As some of the flowers shrivel and die off others open and expose the inside of the petals, which is of the most delicate rose-pink, shading into the purest white; whilst the outside is, as has been said, a deep crimson. The flowers when cut and placed in water will last for upwards of a month. The stem is porous and Reed-like, and the crimson cluster of flowers at the top consist of about a hundred blossoms. The Queensland Spear Lily (*D. Palmeri*) is another handsome plant, well worthy of cultivation in some of our larger gardens. Both species flower in the Melbourne Botanic Gardens. Apart from their fine blossoms, these plants are worth growing for their handsome foliage. It belongs to the Amaryllidaceæ.—("Indian Gardening.")

— INFLUENCE OF POOR POTATO SEED.—Small tubers are those not matured, hence inferior in quality and vitality. An overlooked source of imperfect seed, says a writer in a transatlantic contemporary, is allowing the first sprouts to grow to such an extent before planting that they must be either broken off entirely, or will become bruised in the necessary handling, which will kill them. The second sprouts are smaller and less vigorous, produce a weaker plant, which is more subject to fungus.

— AUTUMNAL HUES.—One of the most brilliant of Nature's effects—the autumnal tints of leaves—is little understood even now. From laboratory experiments and observations in the Alps, Mr. E. Overton concludes that the red colouring matters are chiefly due to sugar, and are in most cases unions of tannin compounds with sugar. Autumnal sunshine, says a contemporary, favours the production of sugar and the chemical process leading to the formation of the pigment, while the low temperature prevents conversion of the sugar into starch.

— MR. GEORGE HARRIS.—We have announced, on the authority of Mr. Harris, late of Alnwick Castle Gardens, that he had accepted a position as exponent on gardening under the Northumberland County Council. He now desires us to state that he has resigned that appointment, and purchased land at Kendal Green, Westernhope, near Newcastle, whereon to erect glass structures for growing produce for market. The County Council position was declined by another undoubtedly able teacher on gardening, Mr. D. T. Fish, because of the peculiarity of the demands.

— ANTHOCERCIS VISCOSA.—This softwooded New Holland plant is seldom seen in gardens, though it is of easy cultivation and showy. The leaves are 2½ inches long and covered with sticky glands. The flowers are usually produced singly from the axils of the leaves. They are 2 inches across, with a tube half an inch deep. With the exception of the inside of the tube, which is marked with green, they are pure white. Cuttings root readily in sandy soil in a close case, and good flowering plants may be had in a few months. A mixture of equal parts of good loam and peat, with a good quantity of sharp sand, is a suitable compost, and it will be found advisable to stop the plants frequently when young. A greenhouse from which frost is excluded is all that is necessary to grow the plant successfully.—W. D.

— CINERARIAS, CYCLAMENS, AND PRIMULAS.—In looking over the well known establishment of Messrs. Criban & Son, Oldfield Nurseries, Altrincham, one could not help being impressed with the display of the above charming winter and spring flowering plants. Cinerarias were of medium size, but carried blooms of the finest form; the colours, too, embraced almost every conceivable shade. The Cyclamens have been carefully tended, and no pains spared to try to make improvements in the somewhat limited colour of these popular plants, and I noticed several with distinct shades. The plants were admirably grown and profusely flowered, making in all a splendid show. As with the two former the Primulas were quite up to the average in every respect. Dwarf, sturdy plants, and handsome heads of bloom are the leading characteristics of the strain.—A VISITOR.

— HESSLE GARDENERS' SOCIETY.—The last meeting of the above Society was held on March 28th, when the prize essays, which are competed for by the junior members of the Society, were read. They are decided in two classes—viz., under eighteen years of age, and over, the subject being for the former, "The Advantages of Keeping a Diary of Horticultural Operations," and the latter, "The Formation of a Kitchen Garden and its Cropping." Unfortunately the competitors were not quite so numerous as in previous years. The successful essayists in the class for those under eighteen years of age were Mr. G. Mason and Mr. C. Wattam; in the class for those over eighteen years, Mr. J. O'Donoghue, Tranby Croft, and Mr. M. Skinner, Bishop Burton Hall, were placed in the order named. After the reading of the prize essays a general review of the session was indulged in and proved of much interest and instruction. The interest in this popular Society is well maintained, and the finances are in a most satisfactory condition. Mr. Mason presided, and made one of his humorous speeches, which delighted all present. Mr. Barker showed a group of hybrid Phaius with about fifty varieties of cut blooms of *Dendrobium nobile*, and a collection of *Odontoglossum Rossi majus*. Mr. Hardy moved "That the best thanks of the Society be given to Mr. Barker for the beautiful exhibits of Orchidaceous plants which he had placed before the members from time to time," which was seconded by Mr. G. Picker, and carried with acclamation. The usual votes of thanks to all the officers were passed, and so ended the most successful session this Society has yet enjoyed.—J. T. B., *Hessle*.

— **FLORILEGIUM HARLEMENSE.**—From Mr. de Erven Loosjes, Haarlem, we have just received the ninth issue of this splendid work, of which the excellence of production continues to be worthy of all praise. The present number comprises Hyacinth Charles Dickens; Double Tulips Rex Rubrorum and La Candeur; and a superb plate of Narcissi Emperor, Empress and Sir Watkin. When the series is complete it will form a most valuable gallery of bulbous and tuberous rooted plants.

— **AMERICAN FRUIT IN GERMANY.**—The officials of the German Foreign Office have notified the United States Embassy that the Government will henceforth admit American Oranges, Lemons, and Raisins without examination, and also that all American fresh and dried fruit will be allowed to pass in bond through Germany without being examined. The decisions are based on the favourable reports of the German experts sent to America. The question whether dried fruit sent abroad is harmless, especially for the transmission of the San José and other insects, and whether the fruit may be imported without previous examination, has not yet been decided. The probability is, says an American contemporary, that the decision will be favourable to American interests.

— **NELSON RECREATION GROUND, BERMONDSEY.**—Nelson Recreation Ground, which has been formed in Kipling Street (late Nelson Street), Bermondsey, was opened on Thursday forenoon. The open space, which was formerly a burial ground attached to Guy's Hospital, has an area of a little over three-quarters of an acre, and is surrounded on all sides by warehouses and other large buildings. It is the only ground in the immediate district now available for public recreation. Half of the purchase money—£4600—was paid by the County Council, and the other half by other bodies. We learn that the Metropolitan Public Gardens Association, in addition to their contribution towards the purchase money, spent £500—a donation from the Trustees of the London Parochial Charities—in laying out the ground.

— **DEVON AND EXETER GARDENERS' ASSOCIATION.**—At the meeting of the Devon and Exeter Gardeners' Association at the Guildhall on March 29th, Mr. G. C. Crabbe, of Prospect Park, Exeter, read a paper on "Pelargoniums: Their Treatment from an Amateur's Standpoint." Pelargoniums, mis-called Geraniums, were a very large family, but all loved a similar soil and treatment. With regard to the soil, rubbish dug up from the garden or knocked out of pots was of no use. A good all-round soil could be made with three parts of loam, one of leaf mould, and one part of coarse sand well mixed. This soil would do either for rooting cuttings or growing plants. Insert cuttings round the edge of a pot, water and place in a shady and airy spot, and in six weeks' time they would become rooted plants. The cuttings should be firmly inserted and kept fairly dry. The young plants should be put in 4½-inch pots. The new plant must not be allowed to run away as it liked. When 8 inches high cut out the growing point, as that compelled the plant to break out at the sides, and allow only those shoots to develop that were seen to be necessary. The plants would grow well for the whole season in these pots. The latter part of the paper dealt with different varieties of the Pelargonium. Mr. J. Abrams, Peamore, occupied the chair.

— **FARMERS AND FRUIT CULTURE.**—Your correspondent "A. D." (page 245) is right, there is room for improvement in our fruit growing, but surely we are improving, if slowly. Some of our sons are being taught the various details connected with the work, as we know there is money in it. But "A. D." seems to think they waste too much valuable time in "hunting and sporting." Do they not need relaxation? And does "A. D." think their time is always wasted while hunting? I think he will find they often go hunting from a business point of view, as he must know that breeding good horses pays, and how can they better dispose of a good horse at a good price than by showing him off to "the Squire" or the "gentleman from town" in the hunting field, making as much, perhaps, from the sale as they would from fruit-growing in a year. Our sons, or the majority of them, have to work hard, early and late, seven days a week, and we must not begrudge them an occasional day's hunting, and if they care to enter their horses for a "point to point," or the cup at the "Hunt" steeplechase, we wish them luck, as we know they still combine business with pleasure. But peg away at them, "A. D.," about improving their orchards and then we shall get better cider. But now I remember our friend does not like cider, as he says it is "good Apples spoilt." There I beg to differ from him, as I know when properly made and kept there is not a more wholesome beverage made. I think if "A. D." were horticultural instructor in our county it would not add to his popularity among the farmers to condemn their hunting and sporting, and say their sparkling champagne cider was "good Apples spoilt."—DOUBLE GLOUCESTER.

— **FLOWERING TREES AND SHRUBS.**—Quite surprising is the recovery from what seemed to be grave injury from cold biting winds and frosts of the Almond, double-blossom Peach, Snowy Mespilus, and other early flowering trees since the weather became soft and showery. Just now all these trees are in glorious bloom, and it naturally leads to the hope that if no appreciable harm has been done to the flowers, that very little harm has been done to fruit bloom. Very marked also has been the sudden flower development seen on the Forsythias, as well as on the Daphnes. The Forsythias are exceedingly graceful, and rank amongst our brightest of early blooming shrubs. We seem at last to have made a fair start for spring bloom and weather now.—WANDERER.

— **AT IT AGAIN.**—Of course they are, and ever will be so long as the brown sparrow clings tenaciously to the haunts of men. I thought how pleasing the bright coloured Crocuses looked as they opened out in response to the call of the balmy sunshine; but the sparrows see them in another light, and rejoice in pecking to pieces the charming flowers. Why they do it I have not yet learned, except it be that they are imbued with an uncontrollable spirit of mischief which must have vent somewhere. In a moment of aggravated rage I drive them from the Crocuses, and they at once give a little chirrup and settle on the Gooseberry and Currant bushes a little further on. Everyone knows what that means, especially when the ground underneath is strewn with the remains of ruined birds. There is nothing for it but to follow them up with the mixture of soot and lime for dusting over the bushes, and while busy with that operation they are back at the Crocuses again. Oh! those sparrows! Can there be wonder that gardeners often lose their tempers?—G.

— **THE HAILSTORM INSURANCE CORPORATION.**—On Monday, March 24th, the annual report and financial statement were presented at Simpson's Hotel of the Nurserymen, Market Gardeners' and General Hailstorm Insurance Corporation, Ltd. This is the fourth annual report, and it is matter for congratulation to all concerned to see how eminently satisfactory is the state of affairs. The directors say they "are pleased to be able to draw attention to the gratifying fact that not only has the premium income been increased by over 27 per cent. and the income from investments largely augmented during the year, but that the ratio of working expenses has been considerably reduced as compared with previous years." They continue, "Notwithstanding the fact that hailstorms occurred in so many different parts of the country, fortunately no damage was done to glass insured with this Corporation, although in several instances the gardens of policy holders were in close proximity to the storm areas." Finances are equally sound. Full particulars of the Corporation can be obtained from the Secretary, Mr. Alex. J. Monro 1 and 2, King Street, Covent Garden, London, W.C.

ROYAL HORTICULTURAL SOCIETY.

SCIENTIFIC COMMITTEE.—Present: Mr. Veitch (in the chair); Dr. Müller, Rev. W. Wilks, Rev. G. Henslow, Hon. Sec.; visitor, Mr. Lees.

Flow of sap in a Sycamore during frost.—Mr. T. R. Bruce, The Old Garrsop, New Galloway, sent the following communication:—"I noticed icicles hanging on a newly cut branch during the whole of last week, and steadily increasing, although the mean temperature of the week was only 30°. The mean temperature of the 24th of March was only 25.7°. The cut branch would be about half an inch in diameter, and some pounds weight of icicles, or pints of sap, have flowed out during the week, and it still continues to flow. The maximum and minimum temperatures were as follows: 19th, 42.5°, 21°; 20th, 42.5°, 23°; 21st, 38.5°, 15°; 22nd, 38°, 21.5°; 23rd, 37.5°, 21.5°; 24th, 40°, 11.5°; 25th, 43°, 23°."

Narcissus, aberrant forms.—Mrs. F. M. Cooper sent some flowers—partly fasciated, partly double, and with coherent ovaries, &c., not unusual sports under cultivation.

Carnations and Chrysanthemums attacked by insects, &c.—Mr. Lees, of Trent Park, New Barnet, exhibited specimens of Pinks and Chrysanthemums, which were forwarded to Mr. McLachlan and Mr. Michael for examination.

Hybrid Narcissi.—With regard to the spontaneous hybrid sent to the meeting on March 14th by Rev. C. Wolley-Dod, Mr. Henslow stated that the pollen was quite shrivelled and probably useless, as Mr. Wolley-Dod had found to be the case with other hybrid Narcissi. He sent also a spontaneous hybrid between *N. triandrus* and the Daffodil. The pollen of this also proved quite effete. He also sent flowers of *N. Johnstoni*, a supposed species intermediate between *triandrus* and the Daffodil, but it resembled the latter much more closely than the one mentioned above, as the corona was almost exactly that of the Daffodil, but of a paler yellow. The pollen proved to be very bad, but still many grains were apparently quite perfect. Mr. Wolley-Dod says that "it is found in various forms, having established an independent existence over large areas of Portugal and N.W. Spain." He adds that it has never been known to seed. The variety sent is called "Queen of Spain," and is the most abundant.

OLD BOTANICAL GARDENS.

REFERRING to these in his "History of Gardening," the late Mr. G. W. Johnson has recorded that "Previous to the reign of Elizabeth (1558—1603) horticulture was considered as little more than a mechanical art. Botany, previous to this period, was almost unknown as a science, and it must be acknowledged that botany is a chief part of the only foundation upon which an enlightened practice of horti-

botanic garden in Switzerland at Zurich in 1560; one was established at Paris in 1570; at Leyden in 1577, Leipzig 1580, Montpellier 1598, Jena 1628, Oxford 1632 (by the Earl of Derby). Sir Jacob and Sir Andrew Balfour endowed one at Edinburgh in 1680, and the Apothecaries' Company that at Chelsea in 1673."

We were led to refer to the work mentioned on reading a highly interesting and profusely illustrated article on the "Botanical Garden of Padua," in part 4, vol. xxii., of the present quarter's issue of the Journal of the Royal Horticultural Society, and we cite a portion of what is said by "Islander" on

THE OLDEST BOTANICAL GARDEN IN THE WORLD.

"In the year 1533, at the suggestion of Bonafede, a new chair was created in the University of Padua, and called 'Lectura Semplicium.' This chair was intended for teaching botany, and is with right claimed to have been the first of its kind in Europe to give public lectures on botanical science. Later on the want was felt of illustrating these lectures with practical examples, and in consequence in the year 1545 the botanical garden was created for this purpose.

"The botanical garden of Padua occupies an area of 20,664 square metres, in the middle of which a circular space, having a diameter of 84 metres, is especially reserved for the different families of plants, according to the natural order of Jussieu. Nearly the whole garden is surrounded by the Alicorno Canal, which at a certain place is captured, and by means of a hydrophore (dating from 1575) is made to pass through the whole garden. In the year 1593 leaden tubing was laid, and at present seventeen fountains supply the watering power of the garden.

"This marvellous old garden, the oldest in the whole world, has many rare plants to show, some of which are almost as old as the garden itself.

"Of these first and foremost must be mentioned the veteran *Vitex Agnus-castus*, which was planted in the year 1550, and was spoken of by Bauhin in 1650 as being then one of the sights of the garden. It is over 5 metres high, and has a circumference of 1 m. 80 cm. During the winter of 1879-80 the intense cold made it lose all its young branches, but after a rather hard struggle for life, and though its trunk is quite deformed and hollow, and its bark corroded, it managed to pull through, and is now as vigorous as ever.

"Next to this comes the famous *Chamærops humilis* (fig. 66) planted in 1595, and up to 1662 known by the Prefects (Directors) of this botanical garden by the name of *Palma humilis*; later, about 1720, through Pontedera, this plant became known as *Chamæriphe* (*Chamæriphe tricarpos*, *spinosa*, *folio flabelliformi*) and only since about 1737, when Linnæus in his '*Musa Cliffortiana*' called it *Chamærops*, has it here become known under this its proper name. This *Chamærops* is formed of twelve principal branches, measuring each about 65 cm. in circumference and reaching to a height of 9 m. 25 cm. As these proportions seem to be larger than those of this species in its wild state, this particular *Chamærops* received the appellation of *arborescens*. The strange fact about the plant is that it seems to have already attained its maximum height in 1720, when Pontedera in his '*Anthologia sive de Floris natura*' spoke about this plant as being 9 m. in height, and having only three main

branches, whereas in 1854 the number of branches is stated to have been nine; whilst the height, since it reached its 9 m., has hardly increased at all.

"When Goethe came to Padua on September 27th, 1786, this Palm attracted his supreme attention, and the thorough study he made of it served him as a basis for his '*Essay on the Metamorphosis of Plants*,' published by him in 1790. Padua, grateful to him for this distinction, recalls this fact in an inscription over the Palm house. [This inscription is reproduced in the R.H.S. Journal.] And when Boito, in 1881, gave his '*Mefistofele*' for the first time in Padua, he was presented with a wreath made of leaves belonging to this *Chamærops*, now always known here under the name of '*Palma di Goethe*.'

FIG. 66.—CHAMÆROPS HUMILIS AT PADUA, AGE 340 YEARS.

culture can be raised. In this reign England was enriched with the first regular establishment for the scientific cultivation of plants in the Physic Garden of Gerard (1547). It was, however, not in England alone that the study and cultivation of plants became more popular, as a desire for the improvement of a knowledge of plants pervaded Europe simultaneously at this period. Padua took the lead by establishing a public Botanic Garden in 1533. Lucas Ghinus at Bologna, who was the first public professor of botany in Europe, was a strenuous advocate of such institutions. By his influence a similar garden was established at Bologna in 1547, where Dr. Turner (who died in 1568) first imbibed much of that knowledge which rendered him eminent in this country. Gesner constructed the first

"Besides this plant Goethe was attracted by the sight of another one formerly known as *Bignonia radicans*, but in fact, considering Goethe described it as 'a blaze of fire, which with its large brick-coloured flowers densely covered the entire wall,' was in reality a *Tecoma grandiflora* (fig. 67), a plant which he had never before seen growing and flowering in the open air.

"But the plant which in this garden is the most conspicuous one in the eyes of the general public, is assuredly the magnificent *Araucaria excelsa*. It was bought in Milan at the age of ten years; it is now seventy years old and measures more than 20 metres in height, and 1 m. 10 cm. in circumference. The building which protects it has already been added to in height for the third time, and would have had to be elevated again, if, some years ago, its top had not been cut, as it will now again be in a few years, the expense needed for heightening the house not having been voted, because the present foundations of the building would not have borne any further addition to its height. This *Araucaria* is in perfect condition, as might be expected when such a plant is entirely under glass during the rougher months of the year: it is symmetrically covered with its feather-like branches, and nobody who has not seen so perfect a specimen can really understand the wonderful beauty of such a tree. The cutting of its top a few years ago had no influence on its general structure, only, one can see that as its branches become scarcer below, its tendency would be to grow vigorously in height. In order to admire its upper part perfectly, a stone staircase leads up for the first 9 metres of its height, and a balcony has been built all round the house, which is octagonal and measures 23 m. 50 cm.

"Then the old *Platanus orientalis*, though a permanent invalid, is still every spring full of leaves and later on of flowers and fruit. The base of its trunk measures 6 m. 50 cm., whereas 1 metre higher it narrows to 70 cm. It was planted about 1680, and is 18 m. high. Its trunk is perfectly hollow, and is large enough to contain several persons inside it; its bark is one mass of humps, knobs, and enormous warts, and the necrosis, from which it suffered and only got rid of a few years ago, left a longitudinal dead strip, forming about the fourth part of its bark."

There are, in addition, several other remarkable trees enumerated in the issue from which this extract is taken.

"For the students a lecture-room, capable of seating 200 persons, was constructed in 1842; and the illustrations for the lectures are contained in the numerous herbaria.

"Books and periodicals are also well provided, the library containing, amongst others, 164 works on botany, mostly used for the identification and nomenclature of plants; 8000 volumes on general botanical subjects, forty different periodicals, and other works like '*Flora Græca*,' '*Flora Danica*,' all the iconographical works of Reichenbach and Jacquin, '*Flora Fluminensis*,' Tenore's '*Flora Neapolitana*,' English botanical works, a complete series of the '*Botanical Magazine*,' Bulliard's '*Champignons*,' Martius' '*Palme et Plantæ Brasilienses*,' the iconographical works of Cupani, Duhamel, Host, Hill, Weinmann, Guallesio, Berlese, Blackwell, Salm-Dyck, Delessert, Waldstein, and Kitaibel, the majority of the '*Botanici Veteres*,' a complete series of Linnæus' editions, and, above all, the very rare edition of the '*Herbarium Apuleji Platonici*' (Rome, 1479), the oldest illustrated work on botany. Pritzl gives the date as 1493, and the name of the author as Pseudo Apuleius."

It will be observed that Mr. Johnson gave the date of the establishment of the Padua Garden as 1533, but according to the writer of the above article it was only "suggested" then, and "created in 1545," but this gave it a start of two years of Bologna, and thus the claim of the former appears to be substantiated as the "oldest botanical garden in the world."

We are indebted to the courtesy of the Editor of the R.H.S. Journal for the illustrations, and some gardeners may like to know that a metre (m.) is a little more than 3 feet 3 inches, and a centimetre (c.m.) about three-eighths of an inch.

FAULTS, FALLACIES, FAILURES IN FRUIT CULTURE.

THERE comes a time in life to most of us when we begin to need the aid of science, in the shape of glasses, to assist nature in the matter of eyesight; and I will at once confess that by gaslight I have to avail myself of these useful, but rather dreaded, aids when studying the pages of "Bradshaw." But the Journal—perish the thought! the

FIG. 67.—TECOMA GRANDIFLORA AT PADUA, AGE 139 YEARS.

Journal is clear of print, and generally clear of expression. Nevertheless, as I studied its pages awhile ago I rubbed my eyes and doubted if I saw clearly, or whether I did not need glasses to interpret what lay before me; then I followed the example of lady readers, and looked for the signature at the foot, and I saw it was that of my neighbour—and no doubt able cultivator—"Professor Luckhurst" (as the notices posted in the next county have it).

To answer the Professor's question, I never heard anyone in the Midlands say "Do not procure trees from the South;" nor did I ever hear of anyone saying such a thing; though, on the other hand, I am constantly being told that Professor Luckhurst rarely fails in his lectures to point out that trees from the south are the only ones worth

having. I have not yet learned why; but although I am open to learn, I am doubtless, as a dweller in the Midlands, somewhat prejudiced in my views. But, to put this question aside, for really it does not need argument, as every practical man who knows anything about fruit trees knows as well as he can be told, that the question of North or South has no value in the matter, whilst soil and culture may have a good deal.

Let us turn to the next point, The manuring of nurseries. Where in the world—no, I mean in England—did the Professor get his “facts” from? I have some little experience of nurseries, and have visited many, but the picture of the abnormally rich land overdone with manure is not the one which I could call to my mind with any truthfulness when recalling my wanderings amongst nurseries. True it is that once in my life I saw a nursery established on old market garden land so rich in manure that it was necessary to double crop the land with vegetables to prevent the trees growing too much, and even then they went mad and produced growths 9 feet in length, which I doubt me would not withstand the attack of a severe frost, nor should I have chosen such trees to plant on a poor soil; but that was in the favoured South. Set against this the hundreds of nurseries and the many hundreds of acres therein which cry with no uncertain voice, as one passes by, “Muck, give me muck.”

One hundred tons per acre! Where outside of the radius supplied by London could it be obtained? Who of us poor midlanders could afford such a luxury? I await the answer with eagerness. I should like to give my land a treat of this kind once in a way, and I think it would bear it. But those trees from the South, are they grown without manure, or is it only in the North that dung grows trees which are so fat that they are apt to melt on a hot day, and fail to grow when transplanted? Oh! my brother nurserymen in the South, you must tell us the secret you possess, it would make our fortunes could we grow good trees without manure.

But when one reads on one finds that, after all, the manure is the right thing, for nurserymen are blamed for advising planters not to use manure in preparing soil for trees. No practical nurseryman would try to lay down a hard and fast law of this kind. If trees are planted in a rich old garden soil, well and good, they do not need manure if the nurseryman has done his duty by them, and, saving a mulching, would be better without it; but, surely, if the question be of planting a newly acquired allotment ground recently broken up from a ploughed and impoverished field, the same advice would not hold good.

One word more. There are “failures,” and I would name as reasons for them poor half-starved trees with no constitution to begin with, also there is such a thing as badly prepared soil, as well as ill-chosen damp situations, badly planted trees, and (most frequently found of all) neglected trees, which, once planted, or stuck in the soil, have no further attention paid to them, around which the hoe does not work and the soil is not cultivated; but it is a “fallacy” to suppose that well grown trees in full vigour, well rooted and well ripened, are to be despised, or that they are more likely to stand still when transplanted than starvelings would be under similar conditions. And as to “faults,” well, we all have them, but certainly we midlanders do not number amongst ours the application of 100 tons of manure per acre to nursery land; nor do southerners, who prefer well grown, sturdy and thrifty trees, “full of fibre,” to long, strong, sappy branches, and correspondingly long, strong, fibreless roots, for one condition is the complement of the other.—A. H. PEARSON, *Chilwell, Notts.*

[Some delay, unavoidable under the circumstances, has occurred in the publication of this rejoinder to the article on page 189, March 9th, to which interested readers may advisably refer. We may say a word on one or two points. (1) We should be surprised if Mr. Luckhurst described himself as a “Professor,” but not in the least if the authors of published announcements should do so to arrest attention, as the habit is not uncommon. (2) In many conversations with Mr. Luckhurst we have never heard him say anything to the effect that “trees from the South are the only ones worth having;” but we have heard him combat alleged local opinion that trees from the South would not succeed in the North. (3) We know of trees from the Midlands and the North succeeding admirably in the South, and trees from the South flourishing equally well in the North. We also know of failures of southern trees both North and South, and northern trees both South and North. So does Mr. Pearson. So does Mr. Luckhurst. So do many gardeners, and not a few nurserymen. It is pitiable to see thousands of good trees spoiled by the blunders of incompetent planters, pruners, and neglectors. It is not less pitiable to see so many worthless trees planted—cheap “culls,” that ought to be burned. We could buy 100 of such trees in an hour, the residue of hundreds more which have been exposed root and branch to the weather for the past three weeks. Mr. Luckhurst has proved his point, that he can grow southern trees in Derbyshire, but he did not prove the failure of midland trees in the same plot, because “the whole of those planted were procured from the South,” and Mr. Pearson is fully entitled to the insertion of his letter]

ROSE SHOW FIXTURES IN 1899.

JUNE.

- 14th (Wednesday).—York†.
24th (Saturday).—Windsor.
27th (Tuesday).—Westminster (N.R.S.).
28th (Wednesday).—Bath, Maidstone, and Croydon.
29th (Thursday).—Canterbury, Eltham, and Norwich.

JULY.

- 1st (Saturday).—Crystal Palace (N.R.S.).
4th (Tuesday).—Gloucester and Harrow.
5th (Wednesday).—Ealing and Hanley*.
6th (Thursday).—Colchester (N.R.S.).
11th (Tuesday).—Hereford and Wolverhampton†.
13th (Thursday).—Brentwood and Helensburgh.
20th (Thursday).—Salterhebble.
25th (Tuesday).—Tibshelf.

* Shows lasting two days. † Shows lasting three days.

The above are all the dates definitely decided upon that have as yet reached me. I shall be glad to receive the fixtures of any Rose shows not named above, or those of any horticultural exhibitions where Roses are made a leading feature, for insertion in future lists.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

ROSE NOTES—PRUNING.

“SHY-GROWING varieties must never be hard pruned, as there is a possibility of crippling them.” Such is the dictum of “Rosarian” on page 237 of the *Journal of Horticulture* of 23rd ult. “When doctors disagree, who shall decide?” Let me give the opinion of a few of our most eminent Rose surgeons.

1, The Rev. H. B. Biron writes in “The Gardener”—“The weak growers cannot be pruned too closely.”

2, Rev. A. Foster-Melliar, in his exhaustive paper read at the National Rose Conference, held in July, 1889, speaks of what he terms the “golden rule” in pruning. Here are his words. “The next question is how many buds are to be kept on each shoot retained, and the answer is to be found in the golden rule of pruning—that more buds are to be left on each shoot in proportion as the plant, both as a variety and an individual, is strong, and less in proportion as it is weak (the italics are mine). To a novice in Rose growing it appears strange at first that we should cut away almost all there is left of a weakly growing and precious variety, which would seem to be almost exterminated by such severity, and yet leave longer shoots on a strong sort, which seems better able to withstand the rough treatment; but the rule is, nevertheless, in strict accordance with the law of Nature, Darwin’s survival of the fittest, and the law of God—‘Whosoever hath, to him shall be given.’”

3, Mr. George Paul says—“Moderate growing Roses should be pruned closely.”

4, Mr. Thos. Rivers’ opinion is as follows:—“The majority of people do not understand the object aimed at in pruning. Roses should be cut back according to strength of shoots or variety. The stronger they are the longer they may be left.”

These four opinions of such eminent specialists must surely suffice to combat the soundness of “Rosarian’s” own judgment.

CATALOGUE INCONGRUITIES.

The question of pruning leads on to another closely allied to it. What is meant by vigorous, robust, and moderate or dwarf growing Roses? This is only written for novices.

The vigorous and robust are perfectly distinct in growth and habit; the dwarf, or moderate, differ from both.

Among the *vigorous* I might name the habits of such as Dupuy Jamain, Abel Carrière, Charles Lefebvre, and Duke of Edinburgh.

The *robust* would be represented by such varieties as Baroness Rothschild and her marvellous white daughter, Merveille de Lyon, Etienne Levet, Marquise de Castellane, and perhaps Marchioness of Londonderry.

Among the *moderate* we find E. Y. Teas, Gustave Piganeau, Xavier Olibo, and Monsieur Noman.

Yet what do I find in a catalogue, one issued by a very large firm? I find the following Roses described as *vigorous*—Augustine Guinois-seau, Monsieur Noman, Baroness Rothschild, Captain Christy, Duke of Wellington, Emilie Hausberg, Etienne Levet, Gustave Piganeau, Xavier Olibo, and Louis Van Houtte; while Her Majesty is dubbed a “bad grower.” I think that when I read in this nurseryman’s

catalogue Cheshunt Hybrid and Thomas Mills as "robust," Gustave Piganeau as "vigorous," and note that the description "moderate" not considered necessary when applied to the growth and habit of a Rose tree, then I shrug my shoulders and say, "Well!"

We will suppose a ease in point. We have often seen a couple of dear ladies of uncertain age at the local Rose Show intensely interested, examining closely through their glasses each flower. "Maria, do look at this one, did you ever see such delicacy in colour and form? Please note it down, I'll spell it out while you write." It is at last written down, "Marguerite Boudet." This, with several others which have attracted the eyes of these good ladies are duly jotted down. Now, Maria and her maiden sister are nothing if not practical, and so they take in between them a gardening paper; they digest what they read, and being warned to grow only vigorous growing Roses, turn to the printed catalogue of the local nurseryman and find perhaps marked as "vigorous" the Marguerite above mentioned, also Louis Van Houtte, Marie Finger, Horace Vernet, Xavier Olibo, and others of Queen Flora's beauties. Twelve months later, and how great is the disappointment! I can personally vouch for many such disappointments during a period of nearly thirty years' experience within the Rose ring.

One of the most accurate catalogues in which the habit of each Rose is most fairly described is, to my mind, that issued by Messrs. Wm. Paul & Son, of Waltham Cross. For instance, he classes among the *moderate* growers the following: A. K. Williams, Duchess of Bedford (one of this firm's own raising), E. Y. Teas, Gustave Piganeau, La France, Louis V. Houtte, Marie Finger, Victor Hugo, Sultan of Zanzibar, Xavier Olibo, and others. This is as it should be, and yet in one catalogue referred to the 1st, 2nd, 5th, 7th, 8th and 9th of the above are generally described as possessing a vigorous habit.

ABOUT TEAS.

To change the subject, or rather cross the road, for we grow our Teas on the other side, on the high land looking towards the neighbouring county of Kent, in which the Rev. H. B. Biron lives, and from whom I will again cite as follows: "With Teas proper, it seems the wisest plan is only to remove the very weak or crowded shoots. Many years I have adopted this method, and have found it better than either close or even moderate pruning. It is impossible to say from what part of a Tea Rose a good shoot will spring. *Often they appear from an old piece of wood with no perceptible eye*" (again my italics).

I think these words would lead to an interesting discussion in your pages, and practical evidence given in time for the pruning of our Teas this month. With the concluding words of the paragraph I am quoting I quite agree. "The more wood a Tea Rose has the better the flowers are. I may here say that I heard lately from one of our most successful Tea growers that he would have no more hard pruning." Is it possible that this grower lives in Ceylon?—J. A. W.

NEW SEEDLING PEDIGREE ROSES.

ON page 237 of the *Journal of Horticulture* I gave the names of five new Roses to be sent out in the coming May. Other novelties seen last season are also to be distributed, but the following are of such extra merit, and so indispensable to all exhibitors, that a note should at once be made of them, and so save time in the near future, this, of course, applying particularly to those who had not the pleasure of seeing some of them exhibited last season.

Ulster.—A grand variety in every way as regards habit of growth (which is robust) and freedom of bloom. It is a H.P., with blooms of an intense pink; large size and perfect form. Judging from the plants in bloom, this should succeed where Her Majesty fails. This variety was awarded a gold medal in 1897.

Bessie Brown.—This charming Hybrid Tea has met with admiration wherever shown, and deservedly so, for nothing more beautiful could possibly be seen, the shell-like broad petals, of a flesh-like tint, almost looking artificial, either by day or night.

Mrs. Mawley.—Wherever this lovely Tea variety was seen last season, there was only one opinion—viz., that it had come to stay. The blooms are of the finest size and form, and the growth is excellent. The colour is of a soft pink, with lighter shades of pale gold running through, giving the flower a graceful appearance. The two latter were awarded gold medals in 1898.

Shandon.—Another H.T., somewhat after the style of the popular Countess of Caledon, sent out in 1897. This new variety has soft rosy-pink shell-shaped petals, silver tipped, with slight reflex, and is highly perfumed.

In addition to the above four I had the pleasure of thoroughly testing the behaviour of other new seedlings not seen outside the exhibition board.

Mildred Grant.—This is a lovely pure Tea variety. Anything more free blooming I have not had the pleasure of seeing, flowers measured being 4 inches deep and 7 inches in diameter.

Alice Grahame.—This flowers profusely. The colour is almost pure white, save for the faint lemon tinge.

Duchess of Portland.—This has been by some persons considered identical with Kaiserin Augusta Victoria, but growing side by side one had not to look twice to see the difference. The Duchess has a more robust habit, whilst the flowers are of a more intense canary yellow.

Countess of Annesley.—This is a fine variety of a beautiful delicate flesh tint.

Mrs. David McKee.—This is a free growing variety of a creamy white shade with a pink centre.

Many continental varieties were on trial, and several of promise were noted, but as my notes on new seedling pedigree Roses are written with a view to drawing attention to the varieties which are likely to be seen in fine condition during the present season, I must leave the Continental and other sections until I can see them again. One thing that we must admire in Messrs. Dicksons is the thorough earnestness they put into their work, and the courtesy extended to all visitors.—A VISITOR.

WINTER GREENS.

THE brevities which appeared under this heading by "E. D. S.," page 236, were interesting as well as practical, but I could not help being struck with the mixture that supports the text—"Winter Greens." Cauliflowers and Broccoli certainly might take offence at such a title, for they have an aristocratic bearing quite unknown to the more humble cottagers' and servants' hall vegetable, and gardeners, as a rule, would not know or recognise them described as "winter greens." The latter term cannot be taken to represent comprehensively the varieties of the Brassica family, because from all time it has been taken as descriptive of the various sorts of *Borecole*. That these are a splendid vegetable for everyday use no one can dispute, for they do, when purposely treated, withstand the frosty elements better than most vegetables, and supply the table when others fail, and when variety is by no means extensive.

In these there is a great diversity of character, and much stress and importance comes from any slight or variable character that the hybridist may impart; but, after all, a little more curl or other slight variation do not make their appearance any better on the table when cooked, and there would seem to be as many flavours as there may be required to suit everyone. There is not, to my mind, any among new or old, tall or dwarf, curled or plain, that can surpass the old Cottagers' Kale in point of quality, freedom in production, or hardy constitution. I will not say that this supplies every need—certainly it does not—for its season of usefulness does not extend late into the spring, and therefore it requires a companion to carry on the supply when the old Cottager persists in supplying flowers instead of edible "greens"—a feast for the eye instead of the body. Variety, however, affords a measure of interest to almost every gardener, more or less, according to the means at his disposal, and will always remain so.

I take it to be a matter of opinion whether drill or broadcast sowing is adopted. "E. D. S." evidently favours the latter course, judging by the advice he gives in his notes under notice. There may be exceptions taken to both practices, and while one may argue in favour of the one, another would stand by the other with the same self-satisfaction. It is, therefore, unnecessary to raise any debating argument in favour of one, or against the other. Personally I adopt both when circumstances require it, but in the open border, when the maincrops are sown, and there are many varieties to deal with, I prefer drills, because I think it is simpler, and the soil can be kept free from weeds so much more easily. Thinly sown in beds broadcast better rooted plants may be drawn for planting, provided they are kept weeded, but when both are allowed to grow together, weeds give one the impression of having greater priority of space, and the plants in their effort to rise to the occasion become sometimes long-legged and awkward for planting purposes. In drills greater facilities are afforded for dealing adversely with the one, and beneficially to the other by the occasional or frequent use of the Dutch hoe.

In small sowings of early vegetables, for which selected spots are sought, broadcast sowing is most suitable, and the same occur with the latest Winter Greens, Broccoli, Savoys, and Cauliflowers. They are thus more easily protected against insect and other interferences, and neither late nor early sowings are permitted to stay so long in the seed bed as maincrops often do, simply because in each case vacant ground is more easily found for planting them.

Just as germination commences, if not before, protection must be given against birds, says "E. D. S.," with which I entirely agree. After various disappointments I now put on nets at the time of seed sowing, from which comes greater ease of mind and better results. Slugs, however, are not so easily kept at bay, at least I have not in my past experience found it to be so, and large earthworms are in showery weather almost as troublesome as slugs.

Early sowings outdoors of Brussels Sprouts, Cauliflowers, and Turnip have felt the pinch of the present wintry weather, even in positions specially favoured by warmth from sunshine and protective and lofty walls. The frost, though severe, was not so destructive until the snowstorms supplied moisture to the soil. Tender seedlings endure the cold but on their moistened leaves frost takes a serious advantage, so much so that their future usefulness cannot be easily gauged.—W. S., Wilts.

making progress now and growing well in the time, however, has arrived for those which begin to coil their roots round the ball to have the pots, which must be thoroughly clean and dry, and the plants employed ought to be also dry and clean, and the pots, covering them with rough parts of moss. The potting material must be composed of turfy loam broken up fairly small. To this add a similar quantity of decomposed manure, of sand and broken charcoal. At this potting add special manure to the bushel of soil will be a good one to build up stout wood, but not proving too strong. The whole should be thoroughly mixed, and

the plants it is essential that they be moist at this time, examine them the previous evening, or at least the day before, which are dry some hours before it is necessary to pot them. The pots do not require to be too large, and will prove as effectual in preventing superfluous moisture as a quantity. Place the plants so that they will be lower than previously when the soil is important that the soil be made firm about the plants in a manner of doing this is to first place a little soil and making it firm with a blunt stick. The quantity of soil regulated by the size of the ball of roots, so that it is not more than it ought to be. When the plant is fixed in the pot, fill in soil round it, shaking it down and making it firm with a blunt stick. More soil can now be introduced and made firmly also. Hard ramming is not required. If the soil is made as firm as the older ball of soil and roots, the plants will meet all requirements.

Of course, that previous to this potting the plants should have well ventilated treatment in a cold frame. The plants must be returned after potting. The frame in which the plants can have all the headroom, and the lights drawn off to expose them fully to the sun, and require it and favourable weather admits. Frames are, of course, the most convenient, but the plants should be potted on a hard ash base near a temporary framework erected over them on which the plants could be placed.

For potting water is not needed very frequently, especially if there is no hot sun, syringing will be necessary. The plants should be kept rather dry, and attention may be assisted to commence vigorously. At this time, air must be given in gradually increasing quantities, and the plants watered immediately the soil dries. The plants should be fully exposed the better. Rough, cold winds are a enemy at this season, and though full exposure is favourable in favourable weather, yet it is advisable to protect the plants in inclement periods. Neat, light stakes must be placed against them to the stems at the time of potting. It is known to be very late in making their first break, and the points pinched out to induce them to do so earlier.

For bushes must have the points stopped at the time the growths resulting have grown to the same length, and may also be stopped. The aim of the cultivator is to secure plants with numerous stems, allowing

The schedule of the thirtieth annual exhibition of the Midland Society is before us, and, as usual, it has been made with care and judgment. Nearly five dozen classes are entered, the principal ones being devoted to the autumn queen, to fruits, plants, and vegetables. There are open air and the prizes ought to be sufficiently good to insure keen competition. We observe that to the money, added in some classes, and fortunately all the articles will be of everyday value to the winners. The Show is on November 15th and 16th in the Town Hall. Mr. W. Road, Rugby, continues to occupy the position of secretary, and furnish all necessary information.

SEASONABLE NOTES ON

EARLIEST FORCED TREES IN POT

THE very early varieties, Early Violet, St. John, are now ripening the fruit on trees started in November, and full exposure to the sun. These Figs are well adapted for supplying early fruit, which is highly appreciated, being extremely wholesome and beneficial to health, containing many seeds. Those fruits now showing signs of ripening have the ventilation increased and be exposed to the sun as far as possible. All cannot have this, but judicious stopping and tying the growths will help them. The temperature at night with a little air, 70° to 75° by day artificially, and full sun. Top ventilation ought to be given at 70°, increase the moisture maintained whilst the fruit is swelling, and cease when ripening commences, and a circulation of air secured constantly, for fruits ripened in a close moisture. Where syringing has been practised red spider makes its appearance, where atmospheric moisture is reduced it spreads rapidly, and effort must be spared to keep the foliage clean up to the top.

Supplies of water are needed at the roots at all stages, and may be syringed at times during the ripening season, but not fruit ripe at one time. For private use Figs should be gathered when gathered, but for marketing purposes or for sale gathered before they are fully ripe. Brown scale is common on the young shoots, and extends to the leaves and fruit, and is under by the timely use of an insecticide, carefully brushed or sponge on the first appearance of the pest, and be treated similarly; the thing is to contest insect before it becomes firmly seated on the plants. A light brushing with water pipes with a cream of sulphur and skim milk has been used on white fly, red spider, and "spot" fungus.

SUCCESSION HOUSES.

Trees permanently planted in borders require more nourishment in proportion to their vigour, their crop area. With the roots restricted to a narrow border, a little of water or liquid manure will be required; those in a large border will need less, but large trees and borders take in Fig culture. Syringe the trees twice a day, the night temperature range from 55° to 60°, 70° to 75° by day of sun, and 80° from sun heat, closing at this degree at 5° to 10°. Keep the growths regulated, thinned at the top, and stop the leading growths at the fifth leaf, partly to stop in the first-crop Figs, and partly to induce good root crop fruit. When the leading growths break again, stop the main shoots to one leaf by taking out the point. Successional growths may be treated similarly, also, these being pinched at the fifth leaf, and afterward there will not be room for them to go forward.

LATE HOUSES.

 experienced last year the plants had a most miserable a
 thought many of them had succumbed, but when the au

BIRMINGHAM GARDENERS' ASSOCIATION.

At the fortnightly meeting held on the 27th ult. (Mr. Walter Jones in the chair), a paper, contributed by Mr. Peter Blair, gardener to the Duke of Sutherland, Trentham Hall, Staffs, entitled, "Grouping Plants for Effect at Horticultural Exhibitions," was read by Mr. James Deans. In his preliminary remarks, the essayist referred to the growing popularity of the grouping of plants for effect, both for house decoration and in the exhibition tent, and strongly advised the decorator to utilise Nature as the basis of his conceptions.

The essayist proceeded: "If the earliest races of mankind had not been amazed by the grandeur and magnitude of the forests, they would have failed in every particular to have been horticulturists, of which ancient history confirms that they were; it is the life of the beautiful you must acquire if you do not already possess it. Unless you have a poetic mind, you cannot realise the harmonious alliance of form and colour. A man must have a poetic feeling, and must be capable of admiring the beauty and grandeur which one meets with in the vales and woodland scenery; rough and wild as it may be, it is Nature, and Art will improve Nature. As one walks through the woods and lands, numerous conceivable designs and information can be gained. Study intensely all you see, fix upon whatever attracts your sympathy, and use all the art which you have acquired by practice. To fix your impressions, so as to be able to reproduce it in grouping of plants, you must make your group solid and bright, real and poetic. The skilful arrangement is, to my mind, a feature quite on a par with the individual merits of the plants. Only in the presence of such a vast array is it possible to understand how much beauty is conferred upon plants and flowers by the fine art of combination. The man who combines well is quite as valuable to the community as he who originates, for although most people may be quick to recognise the charm of a particular Lily or Rose, even the most experienced gather quite new ideas from felicitous blendings."

After advertizing to a multiplicity of plants suitable for decorative purposes, Mr. Blair continued:—"Do not copy your neighbour, but try to copy Nature. You never saw two plants growing in close proximity to each other exactly the same height, and you never saw two pieces of natural scenery alike, so strive to avoid all similarity. I have often seen beautiful groups spoiled by overcrowding, or having too many valuable Orchids and other choice plants at their disposal." Such accessories as rustic arches and bridges of cork bark, which have of late years come into vogue, did not find favour with the essayist, as he considers that they are unnecessary adjuncts, which give the groups a sombre and artificial appearance, that is not in harmony with refined taste. Referring further to the artistic arrangement of groups, he pointed out that it is not always the choicest and most valuable plants that conduce to success, and that the very finest group he had ever seen was quite free from pretentiousness in respect of money value, it having been arranged by Mr. Samuel Thacker, of Nottingham—an amateur, who possesses an inborn genius for effective grouping. Doubtless one of the chief reasons for the introduction of the "Cypherian" rustic arches or bridges was for the more natural disposal of such as especially dependent flowering Orchids and Ferns, and thus imitate their natural habitat.

An interesting and animated discussion followed, there being a diversity of opinion regarding the introduction of cork bark arrangements in groups.

THE "FLOWERS OF THE WEST."

SOME interesting particulars are given in the April "Royal Magazine" regarding the flowers that come from West Cornwall and the Scilly Islands to the London market. The "flowers of the West" hail from two principal districts, the Scilly Isles and the region round about Penzance, the former being by far the more productive of the two. The climate of the Scilly Isles might almost be described as "tropical," chiefly owing to the great influence which the Gulf Stream exerts upon it, and the Islands are, therefore, admirably situated for the cultivation of flowers, which blossom many weeks earlier than in England. Far and away the chief of these flowers are the Narcissi, Gladioli and Wallflowers, however, are also grown, and the latter abound round Penzance.

BY MAIL AND SPECIAL.

From the Scilly Islands the flowers come by steamer to Penzance, thence as a rule by the 4.50 P.M. mail, which reaches Paddington at four o'clock the next morning. But it frequently happens that in the height of the season an extra load of flowers arrives from the Scillies too much to carry by the mail train. In this case one or more specials have to be despatched. If over 10 tons of flowers are to be despatched a special is generally necessary. All the flowers which leave Penzance do not, of course, find their way to Covent Garden. A large proportion go to Manchester and Birmingham, where they secure a very ready market. The season for Scilly flowers is roughly stated from January to Easter.

THE TRADE FALLING OFF.

The following is a list of the number of tons of flowers conveyed from Penzance by the Great Western Railway during the last few years:—

Year.	Tons.	Year.	Tons.	Year.	Tons.	Year.	Tons.	Year.	Tons.
1894...	381	1895...	293	1896...	514	1897...	480	1898...	296

It will be seen that there is a considerable falling away during the past two years. This is said to be accounted for by the fact that the soil of the Scilly Isles has been so taxed with the production of flowers that it has seriously deteriorated.—("Westminster Gazette.")

ROYAL GARDENERS' ORPHAN FUND.

I QUITE agree with your correspondents, Messrs. J. B. Stevenson, page 222, and J. Brown, page 242, as regards the difficulty of getting gardeners to take any interest in the above society. I have asked dozens to become subscribers, but have been met with the same answer: "The Fund is of no benefit to me! My children stand the same chance as those of subscribers!" This ought not to be. It is a good suggestion of Mr. Stevenson's, that as many votes be given to a candidate as there were years during which its father subscribed; also if there be two children of one family elected, they must be the sons or daughters of subscribers only, and that only one child of a non-subscriber be eligible. As regards distance from headquarters, I assure all gardeners that is no object worth a moment's thought. I write after long experience, and more than one attendance at the annual meeting. Never have I seen any of the so-called "string-pulling," but I have seen candidates living in Scotland and Ireland elected, whilst those living in London suburbs were left out.

Again it is said "We have no voice on the Committee, we have no voice in the management," but surely it is quite plain every subscriber cannot be on the Committee? I hate these side stabs. Let any subscribers who are dissatisfied with the working of the society go to the annual meetings. They will be made heartily welcome by the Committee, and the workings of the society explained to the full. I went first an utter stranger, and every courtesy was shown me, and I was given every chance to say my say, and made to feel that though a stranger I was among friends. I would gladly learn others' experience; but if we cannot all meet in Fleet Street, with your kind permission we can give our opinions in your columns. I would in conclusion, congratulate Mr. Stevenson on his four subscribing gardeners; I have only two, out of over sixty new subscribers that I was so happy as to enrol in 1893. Will someone with the good of the "Orphans" at heart try and beat that number in 1899?—JNO. MILES.

[We think Mr. Miles, or anyone else who obtains over sixty annual subscribers to this excellent charity in a year, is deserving of a medal for humanity to distressed widows and children.]

AUSTRALIAN BLACKBERRYLAND.

BLACKBERRIES are so intimately associated with leafy hedgerows in English country lanes that the idea of their growing in rich luxuriance in a land where the order of natural history, as known in the Mother Country, is popularly supposed to be reversed, where the stones of Cherries grow outside the fruit, and trees shed their bark instead of their leaves; yet there is nothing strange or incongruous in English wild fruits thriving in a country where every description of fruit and flower known in Great Britain thrives in perfection. The Sweetbriar, such a favourite in English cottage gardens, grows so rapidly in Australia as to become an agricultural pest, and in parts of New South Wales the Blackberry is so prolific that the fruit is gathered by the ton, in place of the bushel or hundredweight with which English Blackberry gatherers are familiar.

The Blackberry is finest and most abundant on the coast a few miles south of Sydney; and Bulli, one of the leading coastal townships, inhabited chiefly by miners employed in the neighbouring collieries, is rapidly becoming a centre for the annual export of many tons of the delicious fruit. Rising gradually from the coast are the extensive Illawarra Mountain ranges, and in not a few places on the slopes of these, on the lofty summits, and in clearings, the Blackberry bushes occupy many acres of ground. Paddocks which have been cleared and fenced, for cultivation or pasturage, offer no bar to the advance of the Brambles. In more than one instance owners of land have long since ceased to fight the growth, which even bush fires but temporarily retard, so find it more congenial to lease their holdings for a small rental to the pickers, who, as a rule, have anything but an easy time of it. The bushes grow in a most irregular way, presenting in most cases a compact mass of Thorn and Briar many yards deep and several feet high. To reach every part of this mass of entanglement is the Blackberry picker's aim. Yet he succeeds in doing so, and may spend a day in one spot, forcing his way through the bushes as best he can. Generally, he will cut a narrow track to the heart of the bushes, and, establishing a centre at that point, "work" the bushes cleanly and systematically. Billies, buckets, and tins receive the fruit, which may then have to be carried some distance, perhaps right into the township, before being disposed of. Most of the Blackberry pickers are coalminers, and they have the assistance of their wives and families.

In 1894 four tons of Blackberries were sent from Bulli to Sydney. In 1895 the quantity was 17 tons; in 1897 it had risen to 28 tons; in 1898 to 35 tons; and this year (1899) it was expected to reach 100 tons. The Blackberries are purchased, as they are picked, by a local dealer, who finds the demand already exceeding the supply. The berries are collected in carts stationed at suitable points, and sent, packed in tins, to Sydney. In some instances 30s. per ton is paid for the right of entering lands and picking the fruit. Carting is estimated to cost 10s. per ton, and £9 6s. per ton is paid the pickers, being at the rate of 1d. per lb. That there are some smart pickers in the district may be gauged from the fact that the net gain to one family in a single fortnight has been £6. Another good family of pickers has delivered 400 lb weight of fresh Blackberries, the result of one day's work. With the exception of Western Australia and Queensland, the bulk of the jam made from the Bulli Blackberries is

consumed in New South Wales, the duty on sugar prohibiting much export.

Allowing for evaporation of the water in the fruit, it is computed that one ton of Blackberries will turn out about 1½ ton of jam, or 4000 1-lb tins. The greatest demand for Blackberry jam appears to be in the Newcastle district—the Australian “black country,” and chief source of coal supply in the southern hemisphere.—J. PLUMMER, *Sydney, N.S.W.*

BUD DROPPING IN PEACHES.

MR. H. MARKHAM on page 252, in a note respecting the best Peaches, refers incidentally to bud dropping. He says he is at a loss to know the real cause of bud dropping. So are most of us, I presume, or we would take measures to prevent it. In my own case a fine tree of Alexander, which I always rely on to produce fruit in May for a special purpose, has gone altogether wrong this year, the bud dropping occurring to such an extent that I have only half a crop. In this individual case I am inclined to put it down to over-ripening of the wood, and shall take the precaution this year of shading the tree.

I am positive that many cases of bud dropping may be traced directly to want of water in late autumn and winter; and, again, the very early varieties, such as that mentioned above, when grown alongside later sorts for a succession, suffer from over-ripening of the wood. I have been so successful with these precocious kinds in cool houses that I was led to plant Alexander in an early house, and now I wish I had used Hale's Early in place of it. Early Grosse Mignonne is one of the most reliable Peaches in cultivation, but we need something to come in just before it, and Hale's Early, not being so addicted to bud dropping, fills the brief space, though not so early as Alexander.

And though I mention it almost in fear and trembling, the soda and potash insecticide now being used so freely on all hands is in some cases responsible for mischief in this direction. I have seen trees this season badly injured by its use, but I hasten to say that in my opinion the mixture was too strong. Peaches and Nectarines are more susceptible to injury from caustic applications than trees with a thicker bark, and when used, especially under glass, great care is necessary.

For dressing to be essential indeed shows that the culture of the trees has been neglected, for who with the facilities for fumigation, and the ease with which the trees will be kept in good condition, can excuse themselves for allowing them to get so overrun with insects that these remedies are needed?

And after this digression I must say I am entirely at one with your correspondent as to the injury being done before the trees are started, but I do not look for a specific cause. All errors of culture lead up to it, and a general healthy state of the trees is undoubtedly a preventive. Again, our system of disbudding and forcing the trees, to make few long shoots instead of a number of short ones, though needful, is a step in the wrong direction, but of this more anon.—H. R. RICHARDS, *Coldham Hall*.

A WORD FOR GODETIAS.

It is rather curious that we do not always appreciate the beauty of a family of plants fully until someone calls our attention to it. For years Godetias had been more or less under my notice, but only in a commonplace sort of way. It is true they had always been included in the seed order for annuals, and had been sown and grown as a matter of course; but beyond that they did not come in for any special share of attention. I have no doubt there are hundreds who grow this showy and useful annual on lines something similar. A packet of seeds is obtained and sown with the rest of the annuals, and in course of time the flowers appear. They are admired in a way with the rest of the garden's common flowers; and go again without having impressed the grower how really charming they are, and to the many uses they might be put.

Fortunately there are those who have appreciated the beauty of the Godetia, with the result that many pleasing varieties have been introduced. They have their champions too in the shape of growers as well as hybridisers, and in my notebook I find a jotting about Godetias, made last summer in the garden of a flower lover, who takes particular interest in these charming annuals. As the time is at hand when gardeners and amateurs are making plans and preparations for summer adornment, perhaps a few notes on the Godetia, when grown in variety, may not be unacceptable.

Though conversant with the plant in an everyday sense, I had never seen them present such a mass of bloom as in the garden referred to, and for the moment I was tempted to ask what they were. Closer observation, however, proved them to be the old-fashioned Godetias, but grown in separate varieties, by which method each particular colour and character could be noted. The first to attract notice was Lady Albemarle, and perhaps amongst the named sorts this is the best known. Its habit is rather dwarf, and its masses of crimson flowers are very attractive. Another form of the same variety may be obtained, called Lady Albemarle compacta, on account of its habit being closer and more compact. Another pleasing variety in the collection was Duchess of Albany, which grows pyramidal in form, and produces an abundance of soft white flowers. Godetia gloriosa appears to be the darkest flowered of the family. Its habit is close and compact, and its flowers a deep rich red. G. grandiflora rosea flore-pleno is a double-flowered variety, with blooms of a delicate pink shade. One of the most effective varieties in the garden was White Pearl. The flowers are satiny white, and the dwarf, sturdy habit of the plant makes it suitable for growing with other low-growing plants in beds. Another of

the same class, but dwarfier still, is Bijou, which also produces white flowers, and is of a very bushy habit.

The varieties named do not include all that are represented in the Godetia family, but they are sufficient to obtain an interesting collection of these showy flowers. Nothing is more effective in the summer than masses of showy annuals, and many a bare spot might be brightened by the outlay of a few pence and a little labour. Formal ways of furnishing beds and borders have few advocates nowadays, and greater value is, in consequence, set on plants of floriferous and free-growing habit. What more accommodating annual could be desired for the purpose than varieties of the well-known Godetia?—H. H.

NOTES ON ALPINE FLOWERS.

(Continued from page 221.)

CAMPANULA PLANIFLORA.

ALTHOUGH this pretty little Bellflower does not appear in the Kew “Hand-list of Herbaceous Plants,” it is, or at least was, grown in the Royal Gardens, as I recollect seeing a plant in bloom in the Alpine house there. Its garden name is more usually C. nitida, but planiflora is that approved of by botanists at the present time. As a rock-garden plant it stands in the front rank; although in some gardens it does not flower so satisfactorily as the grower would like. Why this is so is somewhat mysterious. Some writers tell us that it requires a stiff, rather strong soil, but, as the writer has amply proved, it flowers as freely as can be desired on a light one. The failure to flower must arise from some obscure cause.

There ought to be in cultivation four varieties of this Campanula. The one usually seen is the single white, but there are also single blue and double blue forms. There was, and it is likely that there is still, a double white form, but I have not seen it in any garden, nor can I find it in any catalogue. C. planiflora forms a pretty plant, with somewhat stiff and rigid habit. The long and rather narrow leaves are of a shining green, as if covered with varnish, and the flat, open flowers are produced several on a stiff stem about 6 inches high. The writer has not grown it from seed, but it is easily increased by division in spring or autumn. It was introduced from North America in 1731. It usually flowers about July. Maund's “Botanic Garden” gives an illustration, but it fails to do justice to this little plant. It ought to have a sunny place on the rockery.

SILENE MARITIMA FL.-PL.

In the same volume as that in which Campanula nitida is shown in Maund's work is a drawing of Silene maritima. One is rather surprised that the author did not figure the double form which is referred to in the letterpress that accompanies the plate. The single form of the Sea Catchfly is very plentiful on some of our coasts, and near where the present writer lives it grows in thousands. Under the name of S. alpina, practically the same plant, it is to be found on some of our British mountains. The double form is one of our best rock plants, and is generally a favourite when seen hanging over a ledge of rockwork with its glaucous leaves and its perfectly double flowers, which remind one of a double white Pink. The double Sea Catchfly is quite hardy, and is increased by means of cuttings taken in spring. It likes a soil which is rather poor, and a sunny position, where it will flower profusely from June onwards.

RIBES ALPINUM AUREUM.

By way of variety one can introduce with advantage a short reference to this little golden-leaved Ribes, which may sometimes be used profitably in rockwork of good size. Against a block of dark stone, or between two rocks of the same colour, the yellow leaves of the shrub contrast well, and it may thus relieve what would otherwise be a gloomy corner. It grows about 3 feet high, and has yellowish flowers, followed by insipid scarlet fruit, from whose want of flavour it receives the name of “Tasteless Mountain Currant.” The yellow-leaved variety under notice does not flower so freely as the type, but that is of little consequence, as its value depends upon the colour of its leaves. It may be grown in any soil.

PHUOPSIS STYLOSA.

Such is the now recognised name of a flower better known as Crucianella stylosa. It is one of those plants whose good and evil qualities may be said to be pretty equally balanced—if, indeed, we do not say that its defects are rather greater than its merits. The faults may be summed up as two. 1st, The peculiar odour it gives off after rain, or in the evening. (It is like that of some of the Acacias, but can be discerned for some distance off when the plant is wet). 2, The Phuopsis is of rather creeping habit, and is prone to spread a little too rapidly for the welfare of other and choicer plants. For the first of these faults there is no remedy; for the second a timely warning may lead to the plant being placed where it cannot do any harm.

Against these disadvantages Phuopsis stylosa has some good qualities. It is hardy, and easily grown in almost any soil; it flowers very freely for a long time; its flowers are pretty, and uncommon looking; and it looks well hanging over a stone. The blooms are arranged in a round head, each flower having projecting stamens, which add considerably to the beauty and character of the flowers. The blooms are pink, and there is also a brighter coloured variety, known as P. stylosa splendens. Phuopsis stylosa is readily raised from seed, but it increases so rapidly at the root that division is the method usually adopted. It comes from the Caucasus.—ALPINUS.

(To be continued.)

THE YOUNG GARDENERS' DOMAIN.

A WORD OF THANKS TO MR. THOMSON.

AS one of the oldest writers in the "Young Gardeners' Domain," I beg to heartily thank Mr. Thomson for his kind and encouraging remarks on page 202. I trust that many of my fellow gardeners will not be slow to turn his sound advice into practice. I have always considered that much can be learnt by the aid of "our Journal," and we who profit considerably thereby ought to consider it a great privilege to add our mite of experience in return for all we have received. I wish more new writers would avail themselves of these advantages, which are certainly for their own benefit. I hope that ere many weeks have passed Mr. Thomson will see results from his teaching, so that when he addresses us again he will be more than satisfied with the efforts to follow in the path he has so ably pointed out.—J. F. D., *Yorks.*

LIBONIAS.

THESE pretty greenhouse plants are not so extensively grown as they deserve to be. They flower during the dullest months of the year, and with their free and compact habit, should receive the admiration of all. They are valuable for conservatory embellishment, and the cheerful scarlet and yellow flowers of floribunda stand remarkably well in a cut state. *Libonia penrhosiensis* is quite as free flowering, and considered to surpass even floribunda. The colour is rich crimson red.

The cultural requirements of Libonias are simple. They succeed admirably in pits through the summer months if care is taken to keep them free from thrips and red spider, and a light shade is provided in the hottest weather. A substantial compost of rich fibrous loam, leaf mould, and mortar rubble, with a fair sprinkling of sand and sweet horse droppings, will be found suitable. No difficulty will be experienced in obtaining useful plants from cuttings rooted now. Never allow the plants to become root-bound in small pots, but keep them growing vigorously with copious supplies of manure water until they are set with flower buds. At this stage an intermediate temperature is necessary, or loss of foliage will ensue, which greatly detracts from the appearance of the plants.—F. W. G.

ONIONS.

THE Onion is grown more or less in every garden. The piece of ground chosen for the spring sowing should be well manured and deeply dug at the end of autumn so that the frost can get well into it. As regards sowing no hard and fast rule can be made—it has to be done according to the weather. Early in March is the best if the weather permits. Make the ground firm and level before sowing, and draw the rows about an inch in depth and a foot apart, as this will leave plenty of room for cleaning. After the seeds are sown cover them and again make firm.

When the seedlings appear above the surface and the rows can be distinctly seen it is a good plan to hoe between them to destroy any weeds that are coming up, and thin the Onions a little where they are very thick. As time goes on and the plants grow attend to the cleaning and thinning, about which I may say that when the final part is completed the Onions when fully developed should be touching each other in the rows, and, as it were, lifting each other out of the ground. About the middle of August the bulbs will be ripe and ready for lifting, and the store should be got in readiness to receive them. Choose a fine day for this operation, and when pulled up, if the weather is dry, let them remain outside for a few days with their roots fully exposed to the sun to give them a complete finish. Care must be taken in storing them, for if they are knocked about and bruised they will decay very quickly.

The time for autumn sowing should be about the middle of August, and every preparation must be made to receive them, carrying out the same instructions as stated for the spring sowing except for the early thinning. These may be left until they are larger, for they come in very useful for salads. I do not think it will be worth mentioning what varieties to sow, as there are at present so many to choose from, and different growers have their own individual favourites.—P. R.

DRAINAGE AND COMPOST.

By this time most of the inside borders and beds of fruit trees and other plants will have been renovated, and preparations are being made for the general potting that is carried on as time and weather permit. Before the season is too far advanced I should like to mention a few items respecting drainage and composts.

With regard to the former, it appears to me that not infrequently too many crocks are used, thus taking up space which the compost ought to fill, whereby the plants would have a deeper root run. Of course this would not apply to such plants as Orchids. It is not the quantity that insures a good drainage, but rather the manner in which they are placed in the pot. A perfectly flat piece is to be avoided for the bottom of the pot, as is one too much the reverse; the former is often the cause of plants becoming waterlogged, while the latter admits the too free passage of water and air. When potting plants that are in time again to be repotted, such as Palms, Pandanus, and *Imantophyllums*, which have thick fleshy roots, judgment must be exercised in regard to size of crocks used. Pieces that would pass through an inch mesh sieve, or thereabouts, are best, as these are easily extracted without mutilating the roots.

Occasionally one reads of carefully drained pots for Tomatoes, which consider is not essential, as the market men generally insert one large crock only, and then cover with the rougher parts of the composts. It

is the careful watering that one ought to study rather than too much drainage.

In speaking of composts, it is not my intention to dwell on those suitable for general purposes, but rather on those where peat is considered such an important article. Some of us, I fear, are apt to use peat too freely for the good of such plants as Ferns, Crotons, Coleus, and Achimenes. I have observed that when peat is used too freely the leaves are rarely so highly coloured or have so much substance as when turfy loam and leaf mould are employed in larger proportions; added to this they do not require such frequent watering, potting, and feeding. That these plants can be grown almost entirely in peat I do not attempt to deny, but in the end the results are not so satisfactory. In several instances I have seen that noble Fern *Adiantum Farleyense* fail to do, chiefly through using too much peat in the compost. Requiring abundance of heat and water as this Fern does, the peat soon becomes sour, and the roots fail to work actively, hence a miserable plant is the result.

Before I conclude, there is still one more article I should like to bring to notice—viz., sand. When we consider that sand is used principally for rendering the compost porous, we should also bear in mind that the more used the poorer the compost becomes, therefore it behoves us to look for something more substantial. This is readily found in charcoal. As a proof of this, the feeding roots of plants may often be seen clinging to charcoal when used in potting, as besides containing a certain amount of potash, it keeps the soil more porous and sweeter than sand.—PARVO.

FRUIT FORCING.

Cherry House.—If the trees are heavily laden with fruit, the demand for nutriment will be greater, as such trees will be less vigorous than those with few fruits, and whilst the former will be benefited by the application of liquid manure, the latter should have clear water as often as required, to maintain the soil in a thoroughly moist condition. Inside borders are more suitable for trees subjected to early forcing, as they afford a better temperature, more corresponding to that of the house or that in which the trees are growing, rendering the progress of the crop more certain and satisfactory, provided due regard be paid to the affording of needful supplies of water. Attend to ventilation and temperature, admitting air from 50°, and liberally at 65°. Syringe the trees twice a day, and keep the surface of the border damped. When the shoots have made four or five joints they should have the points taken out so as to form spurs; but those required for furnishing the trees ought to be tied in position early, and be carefully trained in their full length. Aphides must be kept under by repeated fumigation, as if they obtain a hold, they are not only difficult to exterminate, but spoil the appearance of the fruit.

Pines.—*Suckers or Plants Started Early in March.*—These will now require attention. The pots must be full of roots, but before the plants are root-bound shift them into 10, 11, or 12-inch pots, watering them a day or two previously, so as to have the soil moderately moist when they are potted. Take advantage of the removal of the plants to examine the beds, replenishing them if need be by the addition of fresh tan, mixing it with the old to a depth that will afford the temperature required—namely, 95° at the base of the pots until the roots reach the sides, when 90° is more suitable. Keep the air about such plants well charged with moisture during the time the house is closed, employing no more fire heat than is absolutely necessary to maintain a temperature of 70° to 75° on mild nights. Ventilate slightly at 80°, liberally at 90°, closing with sun heat at 85°, at which time syringe the plants. This treatment will be suitable for fruiting plants, except such as are in bloom, which should not be syringed. Examine the plants twice a week, and water those that require it.

Plants Started into Fruit Early in the Year.—These are fast approaching the flowering stage, and will be benefited by an occasional sprinkling at the time the house is closed, but when in flower they must not be so treated. The foliage being as yet tender, it will be desirable in the case of houses with large panes of glass to afford a slight shading for an hour or two in the hottest part of the day, until the foliage becomes inured to the sun's influence. When the flowering is over the fruit will advance rapidly if the roots are in good condition, and plentiful supplies of weak liquid manure will be requisite. Attend to ventilating early in the morning, commencing when the temperature is at 80°, and closing at 85° with sun heat. Keep the atmosphere moist when the house is closed and the bottom heat is steady at 80° to 90°, night temperature 70°, and 75° by day artificially. As the suckers appear remove all but one to each plant.

Vines.—*Early Houses.*—Where the Vines were started early in December the Grapes will be taking their last swelling, and if any of the bunches are too crowded remove a few of the least promising berries. The inside border must be duly supplied with water or liquid manure, and they must not be allowed to become dry after the Grapes are ripe,

as moisture is necessary for the perfecting of the crop. Choose a bright morning for the watering, and admit air rather freely, so that all superfluous moisture will disappear before ventilation is reduced for the day. A little sweetened manure may be spread on the border to stimulate the roots and prevent the soil cracking. Ventilate night and day when the berries begin colouring, and increase it as they approach ripeness, maintaining, however, a circulation of warm, rather dry air until the Grapes are thoroughly finished, when the temperature should be gradually reduced.

Vines in Flower.—Muscats and other shy-setting Grapes require a rather high temperature to set freely, the points of the bunches being kept well up to the light, and a free circulation of air with a fair supply of atmospheric moisture to prevent the young foliage suffering under the influence of bright sun. The temperature may be maintained at 70° by night, but with the Vines in good condition, free setting is effected with 65°, or even 60° at night, a little air being admitted constantly, and 70° to 75° by day, advancing to 85° or 90° from sun heat. When the Vines are in flower they should be lightly tapped on the stem each day after the houses have been ventilated an hour or two, or they may be brushed over lightly with the hand, which rids the flowers of their caps, sets the stamens free, and disperses the pollen on the stigmas. If there be no pollen visible as a yellowish dust when the bunches are brushed over with the hand, it should be taken from varieties that supply it abundantly, as Alicante and Black Hamburgh, and a large camel's-hair brush be filled with it, and the bunches brushed over after the hand has been drawn over them, refilling the brush with pollen as occasion requires, it being collected on a sheet of white paper turned up at the edges. Alnwick Seedling, Mrs. Pinee, Lady Downe's, and other varieties liable to produce small seedless berries should be carefully fertilised on fine days when the caps part readily from the flowers.

Late Houses.—Accelerate the growth of late Vines by making the most of solar heat, as all long-keeping Grapes cannot be over-ripened for keeping sound for some months after they are removed from the Vines, Lady Downe's ripened early in September being quite fresh in May and June. Ventilate early on fine mornings, as soon as the sun acts on the house, and allow the heat to rise to 80°, with increased ventilation and plenty of moisture, closing in time for it to rise to 85° or 90° from sun heat on fine afternoons. A temperature of 60° at night will be sufficient until the Grapes flower, when 5° more will be necessary to increase the length of the bunches and produce conditions favourable to the setting of the fruit. Gros Colman, Gros Guillaume, and Alicante set freely; but most other kinds of late Grapes require careful artificial impregnation, they being attended to as before advised.

THE KITCHEN GARDEN.

Asparagus.—Directly top growth commences, the time has arrived for forming new beds. Plants obtained from a distance will usually make good progress if properly managed. Asparagus succeeds best on a free working, sandy loamy soil, which will bear enriching without liability to becoming too rich and damp. On the heavier clayey soils, or those most retentive of moisture, the plants are liable to perish during the winter, especially if heavily dressed with stable manure. In the case of the sandy soils, double digging, mixing manure with both spits, adding the more decayed portions to the surface soil is all the preparation needed, and the Asparagus may be grown either on the level or only slightly above it. Greater attention to the drainage should be paid where the planting must be done on heavy soils. When planting, open wide deep drills 15 inches to 18 inches apart, according to the width of the beds, and in these form little mounds of good soil about 15 inches apart, allowing a greater distance if extra fine produce is desired. On these mounds set the plants with their roots spread out evenly, and cover with 3 inches of good, fine soil, or, in the case of lumpy soils, especially prepared compost. On no account dress newly formed beds with salt.

Beet.—Near the end of April is the best time to sow the seed of main crop varieties, especially where there is a tendency of the roots to become coarse. For early use the Turnip-rooted or Egyptian Beet is to be recommended, and this form is also the more profitable for sowing on shallow, hot soils. Seeds may be sown now either on a warm border or quite in the open, thinly in shallow drills 1 foot apart. Sparrows are fond of the young Beet leaves, and by way of protection dust over the seedlings directly they appear, and while yet damp, with soot and lime, repeating as often as necessary.

Borecole and Broccoli.—Those who have not raised plants under glass nor wintered any in seed beds in the open ought to sow seeds of Borecole, early Broccoli, Brussels Sprouts, Cauliflowers, and early Savoy as soon as possible on open borders. Much labour and vexation will probably be saved if the seed is sown thinly broadcast, covering it with sifted soil, or by sowing thinly, in drills drawn 4 inches apart. If raised thickly the plants have first to be pricked out in nursery beds, whereas those raised thinly may be moved direct to where they are to arrive at a serviceable condition. In all the more temperate districts the end of April or first week in May is early enough to sow seed of main crop and late Broccoli, late Cauliflower, Savoy, and Chou de Burghley. Brussels Sprouts, Borecole, and Sprouting Broccoli require the longest period of growth.

Cardoons.—These are not much grown nowadays, but if there is a demand for them they will not be found difficult to cultivate. Each row should be allowed a width of 4 feet. If the soil is comparatively light and non-retentive of moisture, prepare a trench as for Celery, and sow the seed thinly in a shallow drill drawn down the centre. On heavy soils the plants ought to be grown on the level, the site being well

manured and deeply dug. If the ground cannot be got into a free-working, finely divided state, raise the requisite number of plants under glass, and plant out. Fill 4-inch pots with light loamy soil, place three seeds in the centre of each pot, these germinating quickly in gentle heat. Reduce the seedlings to one in each pot, and before the soil becomes crowded with roots harden the plants, planting out 18 inches apart in the rows.

Carrots.—Young plants generally had a trying time of it during the third week in March, and what escaped the frosts were largely cleared off by birds and slugs. In most cases more seeds of the stump-rooted or Horn ought to have been sown soon after mild weather sets in, and advantage should be taken of a showery time to sow the main crop varieties in quantity. If this work is delayed a drying time may cause the coarser lumps of soil to harden and toughen so as to become unworkable. If the Carrot maggot is apt to be troublesome, dust dry wood ashes very lightly along the drills.

Parsnips.—Very large roots are not the best for the kitchen. Comparatively small roots, which may be cooked whole, are to be preferred. Early sowing and allowing much space is conducive to coarseness. If the seed is sown now on ground well manured for a preceding surface-rooting crop in drills not more than 15 inches apart, eventually thinning the plants to about 9 inches asunder, abundance of serviceable roots will result.

THE BEE-KEEPER.

QUEENLESSNESS.

It is important that stocks should always be headed by young fertile queens. There are, however, more colonies queenless during the early spring months than at any other season. This arises from a variety of causes, the chief one being old queens which are allowed to remain at the head of strong colonies after they have become decrepit and worn out. Directly, however, a queen's laying powers are retarded in any way the bees dwindle at a rapid rate, so that a stock that was probably the strongest and best in the apiary the previous season may in the following spring be one of the worst.

If a system of rearing young queens were adopted by bee-keepers who only keep a few stocks, and it is really a very interesting and simple business, losses from this source would be much less frequent. In large apiaries where the bee-keeper devotes much attention to his bees the practice of rearing young queens is almost universal, and if it pays where large interests are at stake, it is only reasonable to suppose it would do so in small apiaries.

It must not be assumed, however, that if young queens are raised annually the loss of stocks in the spring would be a thing of the past, as queens, to be of a strong robust constitution, should be reared during the height of the honey flow, and not, as is often the case, in the autumn. We cannot do better than imitate Nature in this respect. If bees are left to take their chance in ordinary seasons they will usually swarm a few weeks, more or less, according to the weather, before the honey flow is obtained from white Clover. Young queens thus naturally reared are as good as it is possible to obtain them.

This shows the advantage of working on similar lines, and rearing all queens, as far as it is possible, before the middle of July. Were this plan more generally adopted, and the stocks rationally treated afterwards, by seeing that each was crowded with bees, and after the honey flow was over feeding them artificially with sufficient stores to tide over the most severe winter until the following spring, losses from queenlessness in the spring would then be almost nil.

It is not advisable to handle the bees too much at this season to find out if the queen is safe, as with a little practice one can tell by observing the bees whilst at work whether they are queenless. If the bees are carrying in pollen freely, which they will now be doing in most districts, it is a sure sign that the queen is all right. If, on the other hand, the bees remain about the entrance to the hive in a languid manner, it is a certain sign that something is wrong with the queen. Robber bees from strong colonies are usually the first to find out a queenless stock.—AN ENGLISH BEE-KEEPER.

•• All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," 8, Rose Hill Road, Wandsworth, S.W., and NOT to 12, Mitre Court Chambers, Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *nom de plumes* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Castor Oil Plant (*O. F.*).—Yes, the leaf is one from a variety of the species *Ricinus communis*. It is best to sow the seed singly in small pots, and place in heat early in March. Young plants should then be kept growing under glass until early in June, when they may be hardened and put into their permanent positions outside, or used for decorative purposes indoors when sufficiently advanced in growth. The leaves are falling from the present plant in the room because it is too cold and unfavourable for its growth.

Bare Cotoneasters (*Idem*).—The Cotoneasters may be cut down to any extent, or as near the ground as you desire fresh growth to issue from and form compact bushes. The earlier this is done the better, so as to secure well ripened growth this season. Privet bushes are amongst the most tractable of shrubs for cutting, hence selected and much used for divisional hedges. Now is the best time to operate on straggling plants so as to secure compact specimens, shortening irregularities about July.

Sheep Manure for Liquid (*N. B.*).—The sheep manure you have in a barrel is good for Rhubarb or anything requiring nourishment, and is richer than that of cows. A peck is sufficient for 30 gallons of water, and it is advisable to use the clear liquid only for plants in pots; but for Rhubarb the thick may be employed—not, of course, over the stalks or leaves. It is perhaps the best of all liquid manures, but is improved by the addition of a little superphosphate of lime, say $\frac{1}{2}$ oz. to a gallon of water or liquid.

Kainit for Parsley (*Idem*).—This is a good fertiliser for Parsley, being useful also against "canker," as caused by a small grub, *Psila rosæ*. It is best used before sowing the seed, applying about 2 ozs. per square yard. If used now keep it from the hearts of the plants, sprinkling it between the roots or about the plants, not using more than the quantity stated. The rain will wash it in fast enough, or it will soon disappear if the ground be moist, when only it must be applied in the "dry" state. If applied in liquid form use 1 oz. to a gallon of water, and keep this also from the hearts of the plants. You can apply a gallon per square yard, and repeat in the course of about three weeks.

Vines Unsatisfactory (*Mid-Sussex*).—The roots are quite free from phylloxera or any animal or vegetable pest, but the small fibres are dead, though they have been abundant. The shoots, evidently Muscat of Alexandria, are very pale in colour, otherwise healthy and fruitful. One shoot, probably a Black Hamburgh, is also very yellow, yet fruitful and healthy. Of course these are in marked contrast to the other shoot. This is very green and promising, though why it should be so and the others deficient in colour and vigour does not appear, except from varying degrees of constitutional vigour in the respective Vines. The soil appears of a generous nature and well suited for Vines, and as the drainage is good we do not see any reason to be alarmed, for the Vines in the early house would suffer most from the lifting, being brought forward too quickly, as compared with the later varieties in the late house. The soil appears deficient of lime and even of gritty matter. The latter cannot be altered without remaking the border, but you may add the lime with advantage. We should give without delay a dressing of best air-slaked chalk lime and soot in equal parts by measure, using $\frac{1}{2}$ lb. of the mixture

per square yard, and point in very lightly with a fork, or cover, after scratching in, with a little short sweetened stable manure, watering in due course, but avoiding a saturated and sodden condition of the soil. Then, for top-dressing, supply 4 ozs. per square yard of the following mixture:—Bone superphosphate, dry and crumbling, five parts; double sulphate of potash and magnesia, three parts; sulphate of iron, one part; and sulphate of lime three parts. This should be washed in, first moistening the border in the ordinary way, giving the top-dressing, and then washing in moderately. Apply this about three weeks after using the lime and soot.

Coke for Heating (*C. H.*).—The coke made at "pits" in coke ovens is better than that made at gasworks, and also much dearer, hence very little, if indeed any, pit coke is used for horticultural boilers. That from gasworks answers quite well.

Shoots from a Young Vine (*Idem*).—You ask, "If a young Vine when planted is cut back to six or seven buds, should all the growth be rubbed off when they break except the one intended for the rod, or be stopped at four or five joints to help root action, and then be pruned off altogether next pruning time, as they would be opposite the brickwork lower than the trellis commences?" This is a sensible question, and indicates a desire for attaining unto best practice. According to theory, the more growth the more roots; but this does not hold in practice except under an identity of circumstances, the roots being fewer, though larger, in rich than in a relatively poor, but not sterile, soil. Besides, plants differ in pushing fresh rootlets. Some, as Currants, emit roots with or in advance of the swelling buds; and others, as Vines, seldom push roots before the leaves. In the former case growth would be accelerated by root formation, and in the latter the young shoots would draw upon the stored matter, and thus take from the vigour of the leading growth. We have tried both plans and have found it the better practice to allow all the buds to start, and when the leading growth has got leaves partly developed gradually remove the other shoots. The leader then gets all the vigour of the Vine, first pinching them to a few leaves to thicken the stem.

Drooping Disease in Cucumber Plants (*Market Grower*).—The plant submitted is affected by the fungus that produces the well known "rust" in the root stems of seedling French Beans, and also in those of Cucumbers, Melons, Vegetable Marrows, and other cucurbitaceous plants. It also affects the leaves, producing yellow spots, and they die off one here, another there, some at the base of the plant, others at the top, and some at the points between those extremes. It is found on the fruit as "rind spot," and seed sown from such fruit are affected in the embryo—that is, the disease plasma goes over inside the integument of the seed. In the "rust" stage, present on the root stem, it kills or greatly impairs the young plant, few growers potting off such plants, as they have deformed cotyledons or first leaves, a rusty root stem, and a killed radicle; but the plant often pushes roots laterally from the stem above ground, and lives on for a time, or even to the perfecting of fruit or seed, the leaves here and there collapsing suddenly and dying back to the base of the midribs, or even to that of the petiole. The plant may be somewhat improved by earthing up the stem, for the young roots die at the tips or so-called spongioles, and the root hairs, of course, perish. Sometimes "sleepy" disease fungus then intervenes, the root stem turns brown, and eelworms take possession. There exists no swelling, but a dry gangrene, and no browning of the spiral vessels, as obtained in "sleepy" disease above the ground. Where the latter disease occurs, the browning is very decisive between the bark and woody part of the stem where the hyphæ of the fungus traverse. In the main part of the specimen examined there was no root stem "rust," no "sleepy" disease fungus, and no eelworms, but the chief root system was perfectly sound, quite white and healthy, albeit all the root tips and a considerable part of the fibrolets, with their root hairs, were quite brown and dead. In the small dead roots were mycelial hyphæ according with that of *Fusarium solani*, and also the earlier stage of the "sleepy" disease fungus (*Hypomyces solani*)—namely, *Diplocladium solani*. The final or resting stage was not found, nor were any eelworms, but every particle of soil had been removed, and the eelworms, if any were present, may have departed. The "leaf spot" has only a yellowish appearance, not a dark coloured patch, surrounded by a reddish line, as in the case of French Bean leaves, and in the tissues exist extremely minute mycelial hyphæ, this running in the tissue causing the yellowish appearance, as it abstracts the nutrient matter, and "eats up" the chlorophyll. Here, and there appear very pale coloured patches of bodies, closely packed, and under the microscope are seen as slender threads, each bearing a minute spire at its tip, which is the plant known to botanists as *Glœosporium Lindemuthianum* syn. *Colletotrichum lagenarium*. Preventives:—(1) As it is perfectly well known that diseased seed produce diseased plants, and, furthermore, that the seed shows so little external signs of the disease as not to be suspected, it is very important that seed obtained from a district where the disease has recently existed should not be sown. The diseased seeds, however, are usually pitted and blistered. (2) Never pot a seedling that has a brown radicle, and shows the least trace of "rust" in the stem, or is affected with pale blotches in the seed leaves. (3) Remove the diseased plants the moment the fungus is observed, then the disease will disappear, at least for that season. The so-called remedies are really only preventives, such as using a little sulphur on the hot-water pipes, the fumes of which are fatal to the fungus. We have found, however, that the maintaining of a relative high temperature—that is, 65° to 70° at night, 70° to 75° by day on dull days, with the 10° to 20° rise on fine days, with air from 80°, and never having an atmosphere-surcharged with moisture, answers equally well.

The Narcissus (Inquirer).—By far the finest work is Burbidge's, "The Narcissus, its History and Culture," which includes also a scientific review of the genus by Mr. Baker, of Kew. It was published by Lovell Reeve, & Co., London, in 1875, and a secondhand copy may, perhaps, be obtained for about 20s. It contains forty-eight coloured plates. Try to procure it through a local bookseller. "Ye Narcissus or Daffodil," subsequently produced by Messrs. Barr & Sons, 12, King Street, Covent Garden (1s.), is also worth having. We do not remember any later works, but modern varieties are described in catalogues.

Tubular Boilers (E. D.).—Tubular boilers are probably the quickest in heating of all the varied forms, because so much of the water is brought in immediate contact with the fire. The illustrated sheet you send contains both forms—upright and saddle tubular as manufactured by Messrs. J. Weeks & Co. We know of an upright tubular that has been used for more than forty years, and it does its work as well as ever. The saddle tubular of the firm is, we think, comparatively new, and we have had no actual experience with it, but judging by the illustration, which shows its character clearly, we have not the slightest doubt it is a quick, powerful, and efficient boiler. The work of the best of boilers may, however, be frustrated or seriously impeded by the defective arrangements of connected pipes.

Pelargoniums from Eyes (Bradford).—Take the cuttings from the plant, cut transversely below the lowest leaf, and then, placing the knife about half an inch above the eye, cut the stalk in a sloping direction towards the base of the shoot. The large leaves only are available for forming leaf cuttings. The extremities of the shoots should be inserted, like ordinary cuttings, with one joint in the soil, and the growing point above. The cuttings being made as described, drain the cutting pots effectually, and fill them to within half an inch of the rim with sandy loam, leaf mould, and silver sand in equal parts. A little silver sand is then placed in the pot, a quarter of an inch or so, and the cuttings inserted about half an inch deep, each leaf being tied to a small stick, with matting round the footstalk, to maintain it in an erect position. A slight watering is then given, and the pots plunged in a bottom heat of 75°, a top heat of 60° or 70° being afforded. The frame having a moist atmosphere, there is little necessity to water; none should be given so long as the soil remains moist, and the less water needed the better, as the great evil is the liability of the footstalk of the leaf to decay, and the consequent destruction of the eye before a callus is formed. Shade is given for a few days, until the leaves are able to bear the sun; and in this position they remain until the shoot from the eye appears, when they are gradually hardened, and finally potted singly in small pots.

Tuberous Rooted Begonias (W. Raby).—The old tubers should be kept steadily growing till wanted for the flower beds. They ought never to be subjected to much heat, or see the inside of small flower pots. Start them either in a frame over a nearly exhausted hotbed, or in boxes and deep pans in a warm pit, newly started vinery or Peach house. Use a fairly rich compost, and be careful not to over-water and sour this at the outset. They may be placed rather thickly together, and be given more room when growing strongly, or be kept well apart from the first, and all can then be eventually transplanted to the beds with a good ball of soil and roots attached. When the young shoots are about 1 inch in length the tubers may be safely split up into as many pieces as there are well-divided shoots. Surround these divisions with sharp sand and a light loamy compost, place in gentle heat, and water sparingly at first. All will soon develop into strong plants, and do well for the centre of beds, this year's seedlings it need be occupying the front rows. The latter should also be kept out of pots, as they rarely move well from these. When they are getting too large for the pans in which they are thickly pricked out shift them into other pans or boxes, and from these to a bed of soil over a mild hotbed. Gentle rather than a strong dry heat best suits seedlings as well as old plants; shade from bright sunshine must be afforded.

Stopping Vines (Nemo).—When the growths have advanced one or two joints beyond the show for fruit, and there is space, stop so as to apportion the leafage for due exposure. Where there is space it is better to allow shoots with fruit to extend three or four leaves beyond the bunches before taking out their points, then there must be space for lateral growth, it being preferable to allow the laterals to make two or three leaves before stopping, afterwards pinching as space permits. This applies to growths above or level with the bunch, the object being to secure abundant supplies of nutriment to the clusters. The laterals from the leaves below the bunches may be pinched to one first joint and to one leaf afterwards as growth is made. This secures good results in the current season without prejudice to the prospect for another year. Where the space, on the other hand, is limited, it not being possible to carry out the process without crowding, the bearing shoots may be stopped when the leaf at the point determined on is the size of a halfpenny, one or two joints being allowed beyond the bunch. The lateral, level with or above the fruit, must be pinched to one leaf as growth is made, and those below the bunch can be dealt with in a similar manner. This will secure plump basal buds and admit of close pruning, while the principal leaves have full exposure to light, and there is some amount of lateral growth for sustaining root activity and a fair amount of nourishment and stored matter for ancing contingencies.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best

condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (R. L.).—1, *Euonymus latifolius variegatus*; 2, *Veronica Andersoniana variegata*; 3, *Iresine Herbsti*; 4, *Zebrina pendula* (*Tradescantia zebrina*); 5, *Cydonia (Pyrus) japonica*. (J. T.).—*Billbergia nutans*. (R. A.).—1, *Platynerium alciorne*; 2, *Seiaginella Wildenovi*; 3, *Odontoglossum luteo-purpureum*. (H. P.).—1, *Ailium neapolitanum*; 2, *Deutzia crenata flore pleno*; 3, *Dendrobium nobile*, good dark form; 4, *Cypripedium barbatum*; 5, *Odontoglossum Sanderianum*. (G. C. T.).—1, *Dendrobium nobile*; 2, *D. Wardianum*; 3, *Odontoglossum crispum*. (A. J. M.).—1, *Daphne Mezereum*; 2, *Acacia cordata*; 3, *Rhododendron fragrantissimum*; 4, *Acacia Drummondii*. (B. H. W.).—1, *Polypodium pedatum*; 2, *Nephrolepis exaltata*; 3, *Cyrtomium falcatum*; 4, *Pteris umbrosa*; 5, *Asplenium bulbiferum*; 6, *Davallia Moorei*.

CONDENSED MILK.

It is all very well to prepare a Bill—to take infinite pains with every section and clause, to study the pros and cons, to make the thing so pat, and even so that it may injure the interests of no one. All this, we say, is comparatively easy—the initial step in fact. The tug of war comes when the Bill has taken shape and is presented before Parliament and the general public. Then opposition becomes rife.

The unfortunate Minister who has the Bill in hand wishes he had never seen the light, and is ready to consign his numerous advisers body and soul to oblivion. We can sympathise with the man in the minister. It is so hard and so cruel to have a pet scheme, and possibly a most excellent one, exposed to wise and unwise criticism, and to hear and listen to every man, or body of men, who think they are in the "know," and that their advice is priceless.

Very few Bills meet all the needs of the case; at least, so the public seem to think. Measures are, as a rule, not drastic enough. There is a sort of feeling that a bill should go to the root of the matter. People are apt to forget that no really great measure was hurriedly brought about. All great things are of slow growth, and, therefore, more lasting when they have attained that growth. There are measures of a preparatory nature as well as of a final nature.

We prophesied last week that Mr. Long's position at present could not be defined as a very comfortable one. He, as Minister of Agriculture, has brought before the House an excellent Bill for the prevention of food adulteration. Excellent so far as it goes, but now the dogs of war are let loose, and he will be enjoying a very *mauvaise quarte d'heur*.

The first subject for attack is Clause XI., which reads thus:—"Every tin or other receptacle containing condensed, separated, or skimmed milk, must bear a label on which the words separated or skimmed milk, as the case may require, are printed in large and legible type," and so on, *re* penalties.

Now this does not quite meet the doctors' view of the urgency of the case. They think the regulations, and possibly the punishment awarded to breach of the regulation, not stringent enough. And their arguments have some weight. We look upon doctors as disease curers. We ought to take a wider view, and look upon them as disease preventors. That is far the nobler calling. It means so much pain, so much death averted, so much more ease and comfort for the whole human race.

We have often urged the necessity for a milk diet for the young and for the invalid; but when we said milk diet, we meant the pure unadulterated fluid. In crowded streets and alleys the milkcart is not so frequent a visitor as it should be. The pennies for fresh milk are not always to be found; and if found, there is great difficulty in finding a suitable place where the precious milk may be kept sweet and wholesome. This difficulty is not an exaggerated one. Try yourself, kind reader, to keep milk sweet in one room, which has to serve as parlour, dining and bedroom for a family, and then you can enter into the difficulties of an East-end mother. There are babies everywhere, and alas! invalids too; and a great trade is done in tins of condensed milk—small portions easily consumed, and fitted for small purses.

Now, condensed milk as first made was a most excellent substitute for the genuine article—easy of transport, digestible, and wholesome. It contained all the valuable properties, with the addition of a little sugar. But the manufacturers ate of the tree of knowledge, and for fresh milk substituted separated or skimmed milk, and were able thus to give the consumer a benefit in the matter of price at the expense of quality. The ignorant mother or nurse delighted in the cheaper article, little guessing the serious harm done to her charges by feeding them with a substance from which the most valuable part was extracted.

We have heard it argued that skim milk is fine food for the baby, but the doctors do not agree to that axiom. They are claiming that the ignorant public must be protected from itself; they urge that all this weakened milk (we use that word for want of a better) should be classed as "casine," and for distinction's sake be marked with a large K, and that on the label should be clearly printed, "unsuitable for infants and invalids." We are every now and again shocked by statistics regarding infant mortality in great towns, and although the atmospheric surroundings leave much to be desired, it is really the inadequate feeding that is at the bottom of the mischief. A child is the father of the man, and it behoves those in charge of the child to see that it has a fair chance to become a healthy member of society.

One doctor gives in his evidence a rather startling fact *re* this cheap condensed milk. "Practically 40 per cent. of the children who died in his district last summer died from the effect of taking condensed milk." It is worse than useless, as it blocks the way against wholesome nourishing food. If children are thus killed off in this wholesale manner, what of those who do not actually succumb? Another doctor, speaking most emphatically, declares this food (?) to be most productive of rickets and a debilitated constitution. How are people to be taught to take care of themselves? It is only by constantly hammering away at the same old subject. Something has to be done, something made or invented and presented to the public in an attractive and cheap form.

Margarine for butter, we presume, does not really hurt the consumer; he hates to be robbed if he knows it; but here the most helpless portion of the population is daily robbed, not of a dainty or luxury, but of that very part of their food which is calculated to preserve them in health and bring them to maturity. The chemist and the farmer must combine a pure food, easily kept and easily purchased.

WORK ON THE HOME FARM.

Thousand-headed Kale may be sown now for September use in succession to early Cabbage. The treatment is very similar to that required for Swedes, except that the date of sowing is so much earlier. Sow 3 lbs. per acre, and thin them with a narrow hoe when large enough.

Wheats have suffered from the cold weather and show further signs of weakness. The thin crops may revive without assistance, but the very full over-thick pieces may need a little help if they are to keep up the proper rate of progress and produce a good ear. One cwt. of nitrate of soda per acre may mean the difference between a full crop and half of one, but if nitrate is to be applied for Wheat it must be put on in April, so that the nitrogen may be utilised by the plant before the ears make their appearance.

Potatoes are being planted very favourably, the frost has pulverised the ridges, and the mould is splendid; 2 cwt. of sulphate of ammonia and 3 cwt. superphosphate should be a good dressing for 1 acre, and help the plants to make a good start. Up-to-Dates are all the rage this season, as we suppose British Queen will be next year, and something else in 1901. We think some of the older varieties still worth growing. Bruce and Maincrop are good average croppers, and the latter still unrivalled for quality and price-fetching. Lambs are doing well, but have to do with a very casual look at the new pastures for fear of adding to the frost damage.

Cattle should be out, but there is nothing to turn them out to. They will, however, be better out if only for a few hours every day; they will pick a little grass and be getting hardened, whilst the exercise will give zest to their appetites and keep them healthy. When turned out for good, cake should be continued for a short time, and gradually diminished as pastures improve.

REMARKS.

26th.—Rain till 4 A.M.; bright sun all day, halo in afternoon.
27th.—Faint sun at times in morning; slight showers in afternoon.
28th.—Overcast generally, but occasional sun in morning; rain in evening.
29th.—S.W. gale and bright sunshine in morning; cloudy at times afternoon.
30th.—Overcast morning; sunny afternoon.
31st.—Rain from 4 A.M. to 9 A.M., then generally overcast, but gleams of sun at midday.
1st.—Fair, but almost sunless; spots of rain at noon and 5 P.M.
Temperature nearly 20° higher than in the previous week; a very remarkable rise, sharper than has occurred for at least fourteen years. Rain still deficient.—G. J. SYMONS.

BARR'S PURE GRASS SEEDS

For Lawns, Tennis Courts & Cricket Grounds.

The following mixtures are composed of **PURE GRASS SEEDS** only, which have been thoroughly cleaned and carefully mixed. They cannot fail to give the most satisfactory results.

We sell the Seed by weight, which is the only correct method of estimating quantity needed for a given space.

BARR'S "THAMES EMBANKMENT" GRASS SEEDS, for Parks, &c.—A special mixture which has been found very successful in many public and private parks and squares around London and throughout the country. Per lb., 1/3; per 10lb., 10/6; per 20lb., 20/-.

BARR'S "STANDARD" GRASS SEEDS, for Garden Lawns, Golf Links, Cricket Grounds, &c.—In this mixture there is a larger quantity of dwarf, fine-leaved Grasses than in Barr's "Thames Embankment." Per lb., 1/6; per 10lb., 12/6; per 20lb., 22/6.

BARR'S NEW MIXTURE OF DWARF GRASSES, for producing an Extra Fine Smooth Lawn.—A special mixture of the finest-leaved and dwarfest-growing Grasses, producing an EXTRA FINE VELVET TURF, and saving labour in not requiring frequent mowing. Per lb., 2/-; per 10lb., 18/-; per 20lb., 34/-.

Fuller particulars, with Hints on the Management of a Lawn, sent on application.

DAHLIAS! DAHLIAS!! Ware's UNRIVALLED COLLECTION

We are now booking Orders for Delivery
First Week in May.

Special attention is drawn to the two following beautiful
NEW CACTUS VARIETIES for 1899.

Early Orders are solicited as the stock is limited.

E. O. GREENING.—Purple, shaded crimson, medium sized flowers, long and twisted petals; very free flowering; 2½ to 3 feet high. 5/- each.

SYLVIA.—Silvery-lilac shaded rose, splendid shade of colour, wonderfully free blooming, a splendid flower for cutting, lasting very long when cut; flower stem long and stiff; 4 feet in height. 5/- each.

NEW CACTUS DAHLIAS, Vars. of 1898.

Including such sorts as:—ARACHNE, CAPSTAN, FALKA, ISLAND QUEEN, LAVERSTOCK BEAUTY, RUBY, &c. 2/- each

CACTUS DAHLIAS, General Collection.

All the leading varieties. Our selection, 5/- doz.

SINGLE CACTUS DAHLIAS (New Type).
Our selection, 5/- per dozen.

DAHLIAS.—Singles, Pompons, Shows, and Fancies, in great variety. Our selection, 5/- per dozen.

BEGONIAS.

WARE'S GOLD MEDAL and 1st PRIZE STRAIN.
(If required started into growth, an intimation should be given to this effect).

Single—Mixed, 3/- per doz.; 20/- per 100.

„ To colour, 5/- doz.; 32/- per 100.

„ Extra choice, for Conservatory or Exhibition, 9/- and 12/- per doz.; 65/- and 75/- per 100.

„ Named sorts, splendid forms and colours, from 1/6 each.

Double—Mixed, 5/- per doz.; 35/- per 100.

„ To colour, 8/- and 10/- per doz.; 60/- and 80/- 100.

„ Gems for Exhibition, 18/- and 24/- per doz.

„ To name, THE FINEST EVER OFFERED, from 36/- per doz.

DAHLIA CATALOGUE, containing Illustrations of many new sorts, and list of varieties with full descriptions, post free upon application.

N.B.—All Orders amounting to 20/- and upwards when accompanied by cash, are sent Carriage and Packing free.

THOS. S. WARE, LTD, H/LE FARM NURSERIES,
TOTTENHAM, LONDON.

CARNATIONS.—**BORDER CARNATIONS**, in 20 fine named varieties 5/- per doz., 35/- per 100, carriage paid and package free for cash with order Catalogue (150 pages) free.

JOHN FORBES, Nurseryman, Hawick, Scotland.

ASPARAGUS.—This delicious vegetable does not require half the expense usually incurred. For simple instructions see SEED LIST, free on application. Strong roots from 2/6 per 100.—**RICHARD SMITH & CO.**, Nurserymen and Seed Merchants, Worcester.

HOLLYHOCKS. For the best collection of finest named HOLLYHOCKS extant, see Forbes' catalogue (150 pages) free on application.—**JOHN FORBES**, Nurseryman, Hawick, Scotland.

FOWLER'S LAWN SAND.—This preparation is for destroying Daisies and other weeds on lawns, and at the same time stimulating the growth of the grass. If one tin is tried as a sample its value will be at once appreciated. Sales are largely increasing, Tins, 1/-, 2/6, and 5/- each; Kegs, ¼ cwt. 8/6, ½ cwt. 16/-, 1 cwt. 30/-.

CORRY & CO., Ltd., Finsbury Street, London.

PURE WOOD CHARCOAL, Specially Prepared for Horticultural use. Extract from the *Journal of Horticulture*: "Charcoal is invaluable as a manurial agent; each little piece is a pantry full of the good things of this life. There is no cultivated plant which is not benefited by having Charcoal applied to the soil in which it is rooted." Apply for Pamphlet and Prices to the Manufacturers—**HIRST, BROOKE & HIRST, Ltd.**, Leeds.

FLOWER POTS, Machine made.—For Samples (free) and Prices, apply—**TURNER'S, LIMITED**, PORTOBELLO, N.B.

THE GARDEN MANUAL: for the Cultivation and Operations required for the Kitchen Garden, Fruit Garden, Flower Garden, and Florists' Flowers. Illustrated with Engravings and Plans. WORKING AND WINNING.

AN AUTOBIOGRAPHICAL SKETCH.

NOTHING gives us greater satisfaction than seeing gardeners who by their ability, judgment, and persevering industry have won for themselves positions in life much better than those which fall to the lot of so many, worthy though not a few of these may be. We are glad to know of several gardeners who have in different but strictly honourable ways made gratifying progress in life, and can spend, so long as health remains to them, a happy eventide, and with means to obtain all that can be reasonably wanted to the end. How many there are who look forward longingly for such a most desirable result of their career of labour! but, unfortunately, how comparatively few out of the great multitude obtain the object of their hopes!

In the very nature of things it is not to be expected that more than a moiety of gardeners can reach the goal of independency before their strength for work is spent; but the examples of those who have accomplished the great object show the possibility. Whether the moiety who succeed be increased or not depends, to a greater extent than many men realise, on themselves; and at any rate a near approach to the ideal is something well worth striving for by the head and the hands, or, in other words, by the best of work, and the exercise of that valuable quality known as "tact," which may be explained as the most appropriate adaptation of bearing, act, and speech to the circumstances of the moment. Ability and tact are not always combined in the same person, but when they are, *plus* industry, the possessor has a decided advantage over his fellow men, who are lacking in either, in the struggle for supremacy.

There are gardeners, or men known as such, who will not accept the above statements. They may be intellectually incapable of thinking the matter out for themselves (in which case are not fit to be gardeners), and take the easy cut of regarding all successful men as "pampered pets of patronage," and whose only stock in trade is "luck;" but after making allowance for what are called "strokes of

luck" on the one hand and misfortune on the other, the fact remains that those who commence "lounging" for the hoped-for reward soon enough, and who strive as earnestly, perseveringly, and thoughtfully as they "long" for the means of support in the latter days, are much more likely to accomplish the laudable desire than are those who give little thought to the important matter, and who trust to "luck," or that fickle jade "fortune," to carry them through. Some men have been naturally more fortunate than others in obtaining some coveted position, but a proportion of these have made mistakes and failed, while others, by their unquestioned ability and more discreet methods, have increased their reputations and firmly established themselves in the positions that they so worthily fill, or from which they have retired, with so much credit to themselves, to their well won rest.

With very few exceptions these worthies have not won their honours by any mere freaks of fortune but by very real work. They have gone through the drudgery of gardening, and most of them also through another kind of drudgery—self-education—becoming men of considerable and varied mental acquirements, while not ignoring the courtesies or even some of the accomplishments of life; yet never forgetting, nor wishing to forget, they are gardeners. They have struggled through many a hard task and overcome many a difficulty; they have not been tempted by the frivolities of life from the path of duty; have thought seriously over every change from place to place; have made few mistakes or missed few opportunities; and thus by learning, by working, and by waiting, their time and turn have come, and then, being well equipped for various duties, have won success.

These remarks, which are penned mainly in the interests of the men of the future, have been called forth by the perusal of a letter of an unusual nature from a gardener, who by indomitable work of all imaginable kinds in the garden and much out of it, has made his fame and fortune in the prime of life. Here follows the letter, the character of which we have ventured to condense in the heading of this little introduction.

My gardening career at Wimbledon House has been for some time at an end. We left there last autumn, October 20th, after twenty-four years' service, to make room for the place, grounds, and gardens, to be cut up by the building community. By the death of the late Sir Henry W. Peek, Bart., I lost a good master and sincere friend. For years, I can truthfully say, he was a daily companion, always spending any spare time he could with me in walking about his estates, either in Surrey or Devon. When we were separate it was very rare that I passed a day without writing him to post him up in my doings. This I made a golden rule, and it was seldom that a day passed without receiving a letter from him, and I felt his loss the more keenly because of our close association. The inevitable end, however, came, and, as I have said, the estate is being broken up for building purposes, I shall have more time to devote to brick-making, and a few millions of bricks will be wanted.

Although I found plenty to do when I entered on my charge at Wimbledon House, I was soon afterwards further entrusted with the duties of supervising the laying out and planting of Sir Henry's Rousdon estate in Devon, from plans supplied by the late Mr. Robert Marnock. This led to my taking the entire management of the estate, including the direction of tradesmen and employes, and necessitating a journey to Devonshire every ten days or so, and spending half my time there. The management of the two estates—one at Wimbledon, the other close to the Atlantic—was no small undertaking; still, looking ahead to eventualities, I extended my labours by developing a brick-making business on my own account. From an output of 300,000 bricks a few years ago the work steadily advanced to an output of 2½ millions a year, a result not to be despised in these days of strong competition.

During this private work, fully known to Sir Henry Peek, the men and boys in his employment, for whom I have been responsible for and had the direction of, have often exceeded over 100 on the two estates, 150 miles apart. This has been done without any assistance, not even an office boy. The ordering of everything, and the payments for everything, were issued by my hands, after approval by Sir Henry, so that for some years I was heavily taxed, and as I have not had forty-eight consecutive hours to myself on my own account for over twenty years, except on one occasion when I attended a funeral, I think I am now entitled to a little rest, which I hope to enjoy.

I have not sent you any gardening matter for some time, as I felt

I should be inviting people to come and see the nakedness of the land at Wimbledon, as after Sir Henry went away five years ago the house was "shut up," and the grounds have naturally been very rough. It was then that I gave up the Devonshire portion of work, promising to remain at the "old place" with a small staff of men until it was sold. The gardens were extolled by Loudon in the "Suburban Gardener." Sir Henry spent over £30,000 in the rebuilding of glass houses, lodges, offices, and remodelling various portions of the grounds thirty-one years ago. They were long the pride of the neighbourhood, but now being blotted out, and will soon be a thing of the past.

Although the late Sir Henry Peek was a very rich man and exceedingly charitable, few equalling him in that respect, he was nevertheless very precise, and what some might call "exacting." One of the greatest rebukes I ever experienced was one evening on returning from Rousdon to Wimbledon he gave me three-halfpence to get him a "St. James' Gazette" and an "Echo." Arriving at Basingstoke I bought the "St. James'," but no "Echo" was obtainable at any station. On arriving home we retired to his room to do a little business. On bidding him good night he remarked, "But you did not give me my halfpenny." If I had forgotten it for a moment he had not, and on handing it to him he said "it will be very useful to-morrow."

On another occasion he told me he sent one of his clerks to the post-office with a telegram for which they charged one halfpenny too much, as they had counted a compound word as two single words; he instantly sent the clerk back to fetch the halfpenny, as they had no right to charge it. This he did on principle, regardless of the value of the clerk's time going to and fro. I have often thought if the public in general, and gardeners in particular, were, as some are, equally careful and exact in small matters, that an enormous amount of poverty would be prevented and charitable institutions relieved of the pressure of so many would-be pensioners.—J. OLLERHEAD, *the Gardener Brickmaker*.

It will be observed that Mr. Ollerhead does not sink the title of "gardener," to which he has so good a claim; nor is too proud to acknowledge the occupation, which we rather suspect has brought him some wealth; but if he had not been careful in small matters, after the manner of his late and rich employer, he could not have purchased the land and material for raising and distributing 2,500,000 bricks, which he foresaw would be wanted in the architectural transformation of the gardens and ornamental grounds of Wimbledon House.

Though some people, unacquainted with the abysmal depth of the ignorance of editors, appear to think that these hard-working officials know everything, we really do not know the Ollerheadian profit on "a thousand of bricks;" but if they are the same as that of another manufacturer, the 2½ millions alluded to would bring in a very respectable income. The portrait of our "gardener brickmaker" may be seen on the opposite page.

OLD-FASHIONED BEDDING PLANTS.

THREE decades back should, one ventures to think, entitle those plants then in common use for bedding purposes to be termed old-fashioned, for they are, as a rule, so much out of date as to warrant the designation. And, still another reason, there was a certain careless grace and freedom characterising the then new fashion which has long since been improved (?) away. Had it been otherwise, probably, the recent sweeping condemnation of all sorts and conditions of bedding would not have arisen, and what was really a charming feature in the long-ago would be more than tolerated amongst our "up to date" conceits of to-day.

It is only during recent years that we reached the height of fashion in this direction; and the height of fashion is often the height of folly, from which the descent is made with fatal rapidity. One cannot but think so in noting how, in some large gardening establishments, summer bedding has been utterly abolished in favour of perennial hardy plants. There is much to be said for the latter phase, and nothing against it; but should there not be a place in our hearts, and a corner in our gardens, for the old-fashioned bedding plants—that is, as they were ere they were pinched and punished, dwarfed and prostituted into billiard-table levelness?

Thirty years ago the list of tender bedding plants was a limited one. Beds or borders devoted to them were often only sparsely filled. They had not then robbed for half a year the rightful occupants of the houses of their birthright, even then, to some extent, being regarded as usurpers, and treated as supernumeraries; nor did they occupy so long a period under glass. In the South of England, with the advent of May, planting out began, and was generally completed ere the

process now is commenced. The old-time bedders were afforded room to grow, and—they grew. They were, too, I believe, hardier, as well as more vigorous in constitution, than their degenerate descendants. For instance, the old variegated *Pelargonium*, Flower of the Day, which was superseded by Flower of Spring, a form infinitely superior, it is admitted, was inferior to it in hardy qualities. Some eighteen or twenty years since a severe frost was experienced early in June, which cut some large beds of Flower of Spring to the ground. Among these had, inadvertently, been planted some of the old Flower of the Day, and these escaped. Its only merit now is to point a moral, but other things there are for which an early love has made the memories long and lasting.

Of *Lobelias* thirty years ago there was a variety called *Paxtoniana*, and another, I think, *Crystal Palace Gem*; and what charming edgings they made in their rambling propensities. And how rarely seen nowadays is the beautiful old *Calceolaria amplexicaulis*. Among the *Pelargoniums*, *Stella* and *Cybister*, grand representatives of the *Nosegay* type, have never been surpassed for tones of colour and floriferousness; but they were given to rambling, and had to go altogether when the neater habited fiery *Vesuvius* came on the scene. If it is still possible to procure the old *Stella*, and I doubt it, I would strongly advise anyone, with a lingering regard for old-fashioned bedding, to reinstate it in a bed or two which have the harmonious framework of a good expanse of lawn; moreover, to employ it without any edging, and to let it grow comparatively unrestricted.

I have never seen a prettier or more pleasing bed than one formed of the old *Pelargonium Manglesi* and *Verbena venosa* planted promiscuously through it. For some years this was a feature in an old-fashioned garden, the bed being a large informal one raised in tiers by the aid of rustic timber, its position in a sunny nook on the lawn being a particularly happy one. Also comes the memory of a long winding border backed with shrubs. This was planted in longitudinal rows with *Calceolaria amplexicaulis*, *Salvia patens*, one or two varieties of *Pelargoniums* now obsolete, and an odorous foliaged one, still fortunately with us, the old tall *Ageratum*, *Cuphea platycentra*, *Heliotropes*, and a straggling *Lobelia* in front which had a habit of trailing through its neighbours, peeping up in unexpected places in a way of which no well-behaved modern bedder would be guilty. What a treat that border was, surely! and in its thin planting how little it taxed the resources of the old-fashioned gardener and his antique "grinhouse" heated by a flue. Still it was his pride, and he grudged not a good annual dressing of manure and leaf mould in which the occupants grew rampant—a veritable outrage on orthodox bedding, but charming withal.

Among the bedding plants of thirty years ago were *Nierembergia gracilis*, an elegant little plant for bordering; a variegated *Alyssum*, locally known as "*Crystal Palace edging*," *Cineraria maritima*; *Coleus Verschaffelti*, for warm positions, which went well with a bordering of *Gnaphalium lanatum*; such *Pelargoniums* as were then in vogue, which, with other things, have been previously mentioned. Purple King, Snowflake, and Firefly *Verbenas* played a prominent part in old-fashioned bedding arrangements. So vast has been the improvement upon these old types of *Verbenas* that one regrets they are not more commonly employed for summer adornment. Seedlings are of robust habit, and a packet of mixed seeds of a good strain raised annually, and planted out thinly, make an interesting display. Beyond a few pegs to dispose the first strong growths in the way they should go, they give no further trouble, and flower continuously till late autumn.

The later methods of crowded planting: severe restrictions of growth among higher bred bedders, with the heavy demands upon room, time, labour, and expense generally, have brought with them

the Nemesis of fate. Few regret it, and rightly so; but vain would I plead for some, at least, of the old-fashioned bedding plants; and, above all, for the more natural methods employed in their cultivation thirty years ago.—INVICTA.

LONDON GARDENS OVER FIFTY YEARS.

No. 6.

FORTY or fifty years ago there was a well marked contrast between the burial grounds of the East and West of London, with a few exceptions. Neglect and poverty left their impress on most of those of East London, but those of the West were usually made more cheerful by plants and shrubs, expressive of leisure, also, no doubt, of money. But still, some of the latter were far from being what they might have been, even till recently. Addressing his congregation on a Sunday in 1878, the Rev. H. R. Haweis remarked that he had visited their parish ground in Paddington Street, Marylebone, and found oystershells, cast off hair-plaits, crockery, parcels of broken meat, dead and living cats, while on a grave near the centre were twelve kettles, two coal-scuttles, and three old hats! Some folks doubted, but they went and were satisfied. This 2-acre plot is turned into a garden now, having been laid out by the Marylebone Vestry in 1886. The year before, the larger Paddington Churchyard, which contains the grave of Mrs. Siddons, was laid out at a cost of £2000. Mrs. Basil Holmes relates that she was witness to the delight of the children when on the day of opening they were allowed to enter a garden, which seemed to them like fairyland. A valuable little garden, opened by Lady Hobhouse, in June 1892, is that attached to St. Ann's, Soho, and another important one of West London is that upon the much fought-over ground of the Tabernacle, Tottenham Court Road. Farther north we have a fine garden of 7 acres formed from the old ground of St. John's Wood Chapel, which abuts on the Regent's Park.

Some comment has been made upon the scarcity of public gardens, just where we might expect to find most, in that part of London which is often called "the district of the squares." Were all these joined together they would form a park of many acres. There is Russell Square of 10 acres, Grosvenor, Portman, and Euston Squares of about 7 acres each, others of 4 and 5 acres, nearly all now being reserved as private gardens, some very little used by the privileged

few. The need of recreation grounds in this district is lessened by the fact that the extensive West-end parks are within an easy distance; still it has been asked lately why some of these at least should not be open to everybody, and eventually I expect they will. One difficulty is, that occasionally public gardens in certain much frequented districts of London are made the rendezvous of betting men and doubtful characters, against whom precautions would have to be taken.

However, as things are, such squares do serve one purpose of importance—they supply air, which is comparatively free from smoke and noxious gases. Many of these squares, considered as gardens, may be said to have undergone a notable improvement during recent years. The beds are kept more tidy, they contain a greater variety of herbaceous species, while the spring and summer have their special display of flowers. We miss some trees and shrubs we used to see in the squares. Robinias are less numerous now; of *Phillyreas* there were a few, but they have entirely vanished; nor is it often we come upon a *Magnolia* or a *Rhododendron*. But other species have been planted better suited to the atmosphere of London, especially evergreens, which look bright during winter.

Several old authors speak of the pleasant and extensive gardens that belonged to the mansions of nobles along the Strand, two of the larger were those attached to Somerset House and Northumberland

FIG. 69.—MR. J. OLLERHEAD.

House. No living man can remember the old royal gardens of Somerset House, famous in Stuart times, but from its terrace we view the Embankment, where a new garden exists which would amaze worthy Parkinson and his friends of the seventeenth century. The gardens of that stately mansion at Charing Cross, so familiar to by-passers with its lion crowning the front, was removed in 1874, and the gardens also cleared to form new streets. There were some flower beds, but the grounds were chiefly remarkable for its shrubs and trees, many of them of good age, which I was sorry to see cut down. Not distant from the Strand, in sight of it is Covent Garden; that great emporium where every kind of horticultural produce can be purchased, reminds us of the convent garden, really ground belonging at first to Westminster Abbey, and which came into the hands of the Bedford family about 1552. In the Protectorate, the market began with a few stalls under the trees outside the wall of Bedford House.

The neighbourhood of the Strand is not likely to afford many green spaces or flowery nooks, what squares there are, with one exception, being small and paved; its churchyards, mostly small, have not been converted into gardens; those of St. Mary-le-Strand, St. Clement Danes, and St. Paul's, Covent Garden, are closed to the public, nor, if open, would they be attractive. Trafalgar Square, with its 4 acres, has only a few trees and shrubs, much space being occupied by the fountains, the rest is paved. At first some people were desirous of having the centre open, and the corners formed into shrubberies, but this proposal was rejected. The small ground of the Chapel Royal, Savoy, is neatly kept; it belongs to Her Majesty, as Duchess of Lancaster, and was laid out by her some years ago, the seats being given by Lord Meath. A print of the time of George IV. shows sheep grazing there.

Then by the Royal Courts of Justice we have a space of about an acre which was laid out during 1889, and gives a "refresher" to gentlemen of the law, also to others quitting the buildings. Nor is it far from the Strand to the Middle and the Inner Temple Gardens, but these, though worth inspection, we cannot enter without permission. Between the Strand and Westminster Bridge, rising above the Embankment, there yet remains a fragment of the old garden that was attached to the Palace of Whitehall. The Embankment Gardens, which reach from the Temple to Chelsea, with the exception of a small space in Westminster, contain fourteen acres dedicated to the public, and show one of the very notable improvements effected in Victorian London.

All over the metropolis, through the agency of the County Council, the Metropolitan Public Gardens Association, various vestries, and some private persons, the number of trees has increased of late; these have been planted along many roads and in other suitable spots. Mrs. Meynell, who has recently been writing about London localities, is rather inclined to pity its trees, those "that have their roots under pavements, or stand in corners left by the chance medley of London streets." She thinks it is hard upon them to be in perpetual light and never withdraw into the darkness associated with freedom or repose. On the whole our trees do not seem any the worse for this, but some there are that the gaslight may not suit, nor perhaps the electric light. Herein we are returning to the plan of our ancestors, for they had many trees in the old city, only of a few species though, such as the Elm, the Poplar, the Ash, the Oak, but it appears this does not flourish now in London. The Plane, so well adapted for a town life, is no native of Britain; Lord Bacon is stated to have planted the first Oriental Planes in his garden at St. Albans; some of these are said to be still living. For the American Plane we have to thank John Tradescant of Lambeth, who brought it over in 1636.

Somebody made a computation during 1877 that there were then, within what we should call the city limits, about 1200 trees (excluding all mere shrubs), and in this number thirty species or varieties at least, but the predominating tree was the Plane, of which 520 were counted; chiefly, however, of the Western species, of which we have many fine examples in London and its suburbs. But the Eastern species will flourish in towns, and its foliage is denser even than that of its relative, though the two nearly resemble each other. Some Limes have been planted lately. I would like to see more of this tree about; it has a cheerful appearance, and often displays, in London, new leaves towards autumn. Then the common Sycamore, the Maple, and some of its varieties, are occasionally planted, also the Larch, but Pinaceous species generally do not tolerate smoke. It is odd that Horse Chestnuts are not more numerous in our suburbs, since this is quite a tree for towns. Again, there are exotics which make themselves at home among streets, such as the Ailanthus, or "Tree of Heaven," which, for its handsome foliage, might oftener have a place along our roads. Corners and slips which were formerly vacant have now, in many London streets, been planted with shrubs, evergreens being preferred. There might be a freer use of climbers to cover lengths of windowless walls, such as the Clematis, the Jessamine, the Passion Flower, the Periwinkle, in addition to the familiar Ivy.

Writing about the Bermondsey of our time, a journalist comments on the fact that a century ago the district was chiefly rows of marshy fields. Halving that period, however, we can remember its many

ditches, where Watercresses might have been grown, and weather-beaten Willows. Much of Bermondsey was forest long before, and extensive floods sometimes swept along the trees and rushes. It had an abbey of some renown, and its abbey garden names still linger about Bermondsey, which carry us back in thought to the Middle Ages. But horticulture is getting a chance there; gardens are multiplying in that unpromising locality; one of the latest was opened the last day of March by Dr. Cooper, L.C.C. This is situated near London Bridge, and was once the burial ground of Guy's Hospital, but is now becoming partly a garden, partly a gymnasium, and the old trees yet standing will look down upon a cheerful scene before long. There is in summer a good show of flowers in the gardens of St. Mary Magdalene and St. John's, Horseleydown; Southwark Park, too, of 60 acres, is on the border of Bermondsey.—J. R. S. C.

CYMBIDIUM DEVONIANUM.

THOUGH not so large or showy as the Lowianum and giganteum form, this is an interesting and very pretty species, and generally a favourite when properly grown. The plant is of dwarf habit, with pseudo-bulbs only an inch or two in height, and large leaves. The racemes are pendulous, and contain a large number of flowers that are variable in colour, but usually yellow or greenish more or less marked with purple. The lasting quality of the flowers is not so great as that of the above mentioned, but they are not by any means fleeting.

C. Devonianum likes a moist and shady position in an intermediate house, but is best grown in baskets suspended from the roof, both on account of the flowers and the liking it has for light. These baskets must not be unduly large; nor must the plant be frequently disturbed, as it is always more free flowering when well established and a bit pinched for pot room. The compost will be substantial, and may consist of equal parts peat, loam fibre, and chopped sphagnum moss, enough charcoal and crocks being added to insure porosity. C. Devonianum is a native of the Khasia mountains, and is one of the many plants sent home to enrich the Chatsworth collection by Mr. Gibson, who found it growing in vegetable refuse in tree forks.

DENDROBIUM MICANS.

Though raised as far back as 1879, this pretty hybrid is still far from plentiful. In its better forms—i.e. those raised from the Assam form of D. Wardianum instead of the longer stemmed Burmese kind, the plant is dwarf, and the flower of splendid colour and substance, indeed there are few to rival it for colour even now. The sepals are a pretty rosy mauve, and the lip comes nearer D. Wardianum than its other parent, D. lituiflorum. D. micans has the merit of being one of the most free flowering of hybrids, and may be grown under the conditions usually advised for this section.

LÆLIA LOBATA.

With the rush for new hybrids and species among Orchids it is pleasant to note an old friend that is seen flowering only too rarely. L. lobata has long been in cultivation, more or less, but probably quite half of the present day Orchid growers have never seen it in flower. A plant in flower here has very distinct looking blossoms, the side lobes of the lip being a very deep crimson purple tint, the front being much lighter and overlaid with lines of a deeper tint. Lælia lobata is by no means free flowering, but as a matter of fact in many collections plants that are at all shy flowering are never left alone long enough to bloom.

The plant in question is flowering upon pseudo-bulbs that are hanging quite out of the pot, which it has sadly outgrown. But this is better than a prim plant and a flowerless one. Its habit is to flower upon the last year's pseudo-bulbs that rest in sheath, like those of a Cattleya Trianae. Any undue excitement, however, will cause the plants to grow out of season, starting awry at the base before the new bulb is finished, and from such plants it is useless to expect flower sheaths even, let alone flowers.

The plant likes heat, and may, in fact, be grouped for purposes of culture with Cattleya superba or Lælia grandis. It also likes abundant light, being found growing naturally on high cliffs and rocks quite exposed to sun in the neighbourhood of Rio. To place a plant of this kind in a shady house and water it regularly all the year round is to court failure quite as much as to be always pulling the roots about. There is no doubt it is often severely dried in its native place, and under cultivation requires a good rest. This plant is sometimes met with under the name of Lælia Boothiana, this having been given by Reichenbach, but Dr. Lindley first named it as above in 1847.

MASDEVALLIA GELENIANA.

Hybrid Masdevallias are now getting fairly numerous, and very beautiful are some of them. The one named is a hybrid raised, it is said, by Messrs. Sander & Co. from *M. Shuttleworthi* and a variety of *M. Estradæ*. As may be expected, it is a beautiful little plant, with bright yellow sepals, each elongated into a deep yellow tail, as in *M. Shuttleworthi xanthocorys*, the broader portion of these segments being spotted with crimson (fig. 70). It has been frequently exhibited, and though not exactly one of the greatest rarities, is not common, or it would doubtless soon become very plentiful.

SOBRALIA XANTHOLEUCA.

Many have been the complaints that the lovely blossoms of *Sobralia* do not last longer in good condition; but there is always the comforting reflection that numbers are produced successively, and therefore a display kept up for a long time. This species is no better than its fellows in respect of its evanescent character, but it is a lovely form while it lasts, the large flowers being of two distinct shades of yellow, the deeper occurring upon the lip. Its culture may be summed up very briefly; it requires large pots and a liberal amount of compost, ample moisture all the year round, and a shady position in the cool end of the intermediate or Cattleya house.—H. R. R.

BULBOPHYLLUM ERICSONI.

This striking species, having just passed out of flower, enables one to speak more fully of its character and requirements. It is of rather straggling habit, the bulbs being produced some 3 or 4 inches apart, on a creeping rhizome, and is therefore best grown on a raft, with a very little compost under the plant, which must be made thoroughly secure to prevent rocking. The flowers are amongst the largest of the whole family, some 7 or 8 inches across, and are produced seven or eight together on a slender spike. The ground colour of the sepals and petals is a yellowish green, heavily spotted with rich purplish brown; the lip is bright red or reddish purple, and it has a curious rocking arrangement, which is peculiar to some other members of this family. *B. Ericsoni* requires the temperature of the warmest house the whole year round, and was introduced by Messrs. F. Sander & Co. through the collector whose name it bears. It gives off rather a foetid and disagreeable odour, and lasts about a week in flower.

CYPRIPEDIUM BELLATULUM ALBUM.

This beautiful albino is again in flower, and is no doubt one of the loveliest of *Cypripediums*. Like the typical plant it is in many hands a bad grower, but no doubt when our knowledge of its requirements is more advanced it will be as easy to grow as any. Having been successful with it, I would advise anyone to give it a trial, as it is worth its place in the most select collection. The cause of failure I believe is water in a great many cases. It must never be watered above, and great care should be taken that the plant does not receive an excess of water at any time. I have found they succeed best in pure loam fibre from a limestone district, mixed with some fine broken crocks, and a sprinkling of coarse Bedfordshire sand. They should occupy a warm house, and during the winter months very little water will be required; just enough to prevent its shrivelling, as it is apt to damp off if it gets at all wet. It was introduced by Messrs. Charlesworth & Co. of Bradford, through Mr. Moore, from the Shan States, and was first flowered by Sir F. Wigan, Bart., of East Sheen, who received a first-class certificate from the Royal Horticultural Society for it.

DENDROBIUMS INFUNDIBULUM AND JAMESIANUM.

These two members of the nigro-hirsute section are sometimes considered refractory subjects, and are often recommended to be grown in a cool house, but I could never produce a specimen to my satisfaction in such a temperature. Since placing it in a shady corner, however, at the cooler end of an intermediate house the growth has been luxuriant, those of the former often reaching 36 inches in length, and both produce flowers in abundance. The blooms last in perfection for several weeks if kept from the damp. Great care should be taken to keep in check the white scale which infest them, and they should be placed in the smallest pots possible, as sour soil will do immense harm. The compost recommended for the deciduous section will answer their requirements.—J. BARKER, *Hessle*.

MR. W. P. BURKINSHAW'S ORCHIDS, HESSLE.

I HAVE often been puzzled to know where the immense quantity of imported Orchids get to. A short time ago I had an opportunity of inspecting the above named collection, and taking it as a fact that there are probably hundreds of somewhat similar collections in the three kingdoms, one gets one's eyes opened somewhat on the matter. Specialism in some form or other seems to be the order of the day in most trades and professions, horticulture not excepted, and everyone must be pleased to see this development.

Orchid lovers who know the collection under notice, and the excellent manner in which the plants are tended by Mr. Barker the

gardener, will agree with me in saying that a visit must be profitable. There are six span-roofed houses, with ends pointing north and south, filled with Orchids. The four houses filled with *Cattleyas*, *Lælia*, *Dendrobiums*, in fact all the species and varieties that require warm temperatures, are about 18 feet in width; the two filled with cool house Orchids are narrower, having stages on each side and a path in the centre. The internal arrangements of the former are quite different from any I have hitherto seen. Instead of the usual stage the central space is open, or at most is occupied with a group of small Palms, *Clivias*, or any other free-growing stove plants not too liable to encourage insect pests. There are the usual side stages all around on which the plants of the longer bulbous Orchids, such as *Lælia purpurata* and tall *Dendrobes*, are grown. The bulk of the shorter bulbous plants are grown suspended from the roofs. Small iron rods are fixed at right angles to the sashbars; on each side of the span-roof stout hooks are frequent on the bars. As will be seen, it is necessary to have the plants growing in either Orchid baskets or pans. Some few are in ordinary pots with holes under the rim to put the wires through for hanging them.

The general appearance of this arrangement is perhaps not so striking as is the more familiar way; still, anyone who will think out the natural conditions under which the bulk of epiphytal Orchids are

FIG. 70.—MASDEVALLIA GELENIANA.

grown, will at once see there is much in its favour. There can be no doubt but that the best growing atmosphere in the general run of plant houses is that portion distant, say, between 18 inches and 3 feet from the glass roof. Mr. Barker tells me he has no difficulty in getting such varieties as *Cattleya gigas* and *Lælia anceps alba* in variety, to make sheaths and flower spikes quite freely when grown in the way I describe; and, as will be known to many Orchid growers, these varieties do not do this freely under ordinary treatment. No doubt there is a little more trouble in watering them, though judging by the expert way Mr. Barker reached the plants down with a small rod with a hook at its end, it is not in his case more troublesome. He believes in dipping the plants in a movable tub, as this insures a thorough soaking when it is done. On an average this is not required more than once a week he tells me, even in the growing season. Of course there is daily attention as to damping the pots with the syringe, hence the necessity of having free-growing plants underneath, so that they may not be injured by too much moisture. It is only fair to say that the bulk of Mr. Burkinshaw's Orchids are not large specimens as yet, otherwise there would be more difficulty in growing them in this way.

It is necessary to have a small house set apart for exhibiting them when in flower. Speaking broadly, I am convinced that the above mode of growing many species and varieties is the right one. In saying this I do not for one moment lay claim to any special knowledge of Orchid culture.

Amongst the kinds in flower was a healthy plant of *Lælio-Cattleya Bella*, with one spike and three flowers open. It is most beautiful, and as described in the *Journal* of March 30th, page 250, is a hybrid between *Lælia purpurata* and the true old *Cattleya labiata*. The side stage on which it was growing was filled with healthy plants of all the choicest of *Cattleyas* in cultivation, and so far as I could see there

was not one unhealthy. Amongst other Cattleyas in flower were *C. Mendeli*, *C. Warszewiczii*, *delicata*, *Trianae*, also a fine variety of *Lælia elegans*.

So far as Orchids in flower are concerned the sight to see was the house filled with Dendrobies in variety. It was certainly the finest display of Dendrobies I have seen either in a public or private place. It was a cold bleak March day when I was, at Hessele. To be ushered at once into this glass house full of such a mass of floral beauty was, to say the least, a sudden transformation scene, very real and very pleasant to see. My guide is steeped to the lips in hybrid Orchid lore, and soon had me a bit mixed by his rapid and full description of the parentage and history of many of those in flower. I shall not risk your striking this portion of my notes out by not sending them. First, because I am not sufficiently an Orchid expert to write them correctly, unless I had more time with Mr. Barker; and secondly, I should not like to send anything I am not convinced is near the truth. There would be fully five to six thousand flowers of Dendrobiums open and opening when I was there. The largest number of any one variety would be *Dendrobium nobile nobilissimum*. I counted about 500 flowers on one plant. Mr. Barker told me many of his plants were propagated from eyes by himself. Some fine plants of *D. nobile* from the Shan States on the Chinese border were fine both as to colouring and size of flower. This is a splendid type of *D. nobile*, and anyone who can get hold of it true to name will find it well worth their care to cultivate.

I append names of a number of other Dendrobies, either in flower or showing for flower. *D. Ainsworthianum*, *D. nobile Murrhianum*, *eriosumum*, *leucopterum*, *splendidissimum illustre*, *nobile Jesse*, *n. Juno*, *n. Cybele*, *n. Backhousei*, *lituiflorum* from Mr. Chamberlain's collection. *D. nobile hesslensis* is a very distinct variety, with a modest drooping habit of showing its flowers. Some of the individual flowers of *D. nobile* were fully 4 inches across.

In the Cypripedium house were well grown plants, comprising some of the best varieties. Amongst others in flower were *C. Leeatum*, with eight fine flowers; *Calypso*, four flowers; *Pollettianum*; *nitens*, Burkinshaw's variety, with flowers 6 inches deep; some had been open three months. A fine healthy plant of the rare *Angræcum Veitchii* was in this house, also some well flowered plants of *Dendrobium Jamesianum giganteum*, with flowers over 4 inches in diameter. *D. infundibulum* and *formosum*, full of flowers.

There are, as I said before, two houses of cool Orchids. The plants looked in perfect health, and were evidently very happy in their surroundings and general treatment. They are raised up somewhat nearer the glass during the winter than is often seen. An open tank is under each side stage for holding the rain water from the roofs of the houses. Mr. Barker prefers rain water for Orchid watering generally, when he can get it, but has no hesitation in using the laid-on town water supply, which I should presume, from the geological formation of that part, will be of a chalky nature. There were not many *Odontoglossa* in flower when I was there, but it was easy to see that in a few weeks' time there will be a fine display. Perhaps by the time York Gala comes round Mr. Barker may be able to try his hand with a group of them—at any rate I hope so, as such plants and varieties as Mr. Burkinshaw so freely purchases, and his gardener so successfully cultivates, are sure to afford pleasure to the thousands at York.—H. J. C., *Grimston, Tadcaster*.

CAMPANULA PLANIFLORA.

ON page 283, above the signature of "Alpinus," I observe a note on *Campanula planiflora*, *Lamarck*, syn. *C. nitida*, *Aiton*; and it states that the plant was "introduced from America in 1731." This is quite possible, but it is tolerably certain that no such plant has ever been found wild in America, or, as far as the records of Herbaria bear evidence, anywhere else. Botanical writers, from an early date in last century to this day, have followed one another in saying that it was found "in the neighbourhood of Hudson's Bay."

Asa Gray, in his "Flora of North America," vol. ii., page 14, disposes of the plant in the following short summary:—"Long ago described from cultivated specimens, vaguely attributed to North America, is wholly unknown in the wild state: apparently allied to *C. persicifolia*, *L.*, and not North American." On the other hand, De Candolle, in his "Monograph of Campanula," published in 1830 (page 312), devotes a page and a half of quarto size to an attempt to investigate its history; but beyond mentioning its resemblance to *C. persicifolia*, he does not throw much light upon it.

Strangely enough, "Index Kewensis" refers it to *C. pyramidalis*, a species to which it bears a very distant resemblance. I feel little doubt that the different types of the plant are stunted forms, or possibly hybrids of *C. persicifolia*. Plants of it I have bought from nurseries have more than once grown into *C. persicifolia*, and I am now nursing a seedling plant which came up in my garden spontaneously near *C. persicifolia* which has all the characters of *C. planiflora*. If it is a hybrid of *C. persicifolia* I am at a loss to suggest any probable pollen parent for it.—C. WOLLEY DOD, *Edge Hall, Malpas*.

NOTES ON PEACHES.

THE BEST VARIETIES.

ON page 219 "S. Yorks," contributes a very interesting note on the above subject, and although he agrees in the main with my selection of varieties, he points out clearly two instances in which he disagrees with me. The object of my former note was to elicit such criticism, as none of us can know too much about the matter.

In regard to Alexander, let me observe that although I considered a house of this variety would prove a remunerative investment, it was not for that purpose alone I recommended it. Its strong point is that it is the earliest we have, and as such is of great value where very early Peaches are required. Of course we should like it all the better if the fruits were larger and of better colour, but the weak point about nearly all early varieties of fruits is that they are inferior in point of either size, colour, or flavour to later ones. They are grown for their earliness. In regard to the commercial aspect of the case, it is an undoubted fact that the largest and most tempting looking fruits usually command the highest prices, but I also know that in the London markets Peaches in May are eagerly bought up at good prices, and even if the prices obtained are scarcely so good as those for finer fruits a few weeks later, we must not forget that we can obtain a greater number for a given space without overcropping the trees. It is also a great point to be the first in the market, and thus secure an outlet for successional crops.

"S. Yorks," considers Bellegarde and Crimson Galande are probably the two best midseason Peaches in cultivation, whereas the latter was not included in my six. It is certainly a splendid variety, but I have as yet failed to see in what respect it is superior to any of the six I named.

"A Kitchen Gardener" rightly contributed a word of praise for Barrington, which is a fine telling fruit—when we get it, but this variety is not noted for uniformity of excellence in gardens generally. In some soils and situations it succeeds splendidly without any special attention being given, in others the fruits drop far too freely during the stoning period, and split stones are plentiful in those retained on the tree. Applications of lime would probably improve matters to a certain extent, but I fear that until we understand its requirements better, Barrington will have to give way for better doers. "Kitchen Gardener" also casts a decided vote for Crimson Galande; let me ask him which of my six he would cast out to make room for? I presume it would be Royal George because he finds this grand old favourite subject to mildew.

On page 252 I see my friend, Mr. H. Markham, puts in a good word for Dymond when grown on open walls. I quite agree with him, as when I once paid him a visit at Mereworth Castle Gardens in Kent he showed me fine trees of this variety carrying heavy crops of fruit. Mr. Markham also points out that flavour in Peaches is to a great extent regulated by the manner in which the trees are managed; overcropped trees which do not produce fruits with a good depth of flesh can never be noted for their fine flavour; at the same time it is quite possible to grow far heavier crops than the one fruit to a square foot which old writers recommended, and yet have them of large size and fine flavour; it is all a matter of high feeding and skilful attention.

I have had no experience with Goshawk in the open air, but for culture under glass I should not include it in the best six, for although its flavour is excellent it is not one of the best shaped fruits we have, neither does it possess a taking colour.

PEACH TREES DROPPING THEIR BUDS.

ON page 252 Mr. Markham raises once more the vexed question, "What is the cause of early forced Peach trees shedding many of their buds?" My experience is, that it is caused in some instances by an unfavourable condition in one respect, in others by a combination of adverse circumstances. One well-known cause, with which all gardeners are acquainted, is allowing the borders to become too dry during the period that elapses between the gathering of the fruit and the falling of the leaves; and I fear that in many well-managed gardens this point does not receive enough attention. So many other affairs are constantly pressing upon us during the summer months, that it is so easy to slightly neglect this important detail. The results are not perhaps always disastrous, but pronounced enough to cause annoyance when the trees are started.

Again, if red spider secures a firm footing during the time the fruits are ripening, many of the leaves fall prematurely, and unless prompt measures are taken bud-dropping is certain to follow.

There is also the matter of over-ripening the wood. When trees which ripen their fruit in June are grown in light modern houses, spells of hot weather will, under the best of management, cause both wood and leaves to perform their functions too quickly, and they practically reach the resting stage before the cold nights of autumn come. If examined at forcing time the buds on such trees will in some cases be found brown in the centre when cut through; such must, of course, inevitably drop when the trees are started. Shading after the fruit is gathered is of great benefit under such circumstances.

In regard to soil renovation as bearing upon this matter, I think we may safely assume that trees which have perfected good crops of fruit the previous year, and do not gum, are not far wrong at the roots. It is in the matter of watering, and in keeping the foliage clean, that we must look for the remedy for bud-dropping. We must also keep constantly in mind that the best of management in these respects will be nullified by a too free use of fire heat when the trees are started.—H. D.

RECENT WEATHER IN LONDON.—The weather in and around London since Saturday last must have been very unacceptable to travellers, though gardeners would probably be well satisfied. There have been numerous showers and much brilliant sunshine on each day, but fortunately for the expanding buds no frosts have come. In many gardens the rain would be very acceptable, as the supply of moisture is still very short. Wednesday opened bright with a rather cold wind.

— **ROYAL HORTICULTURAL SOCIETY.**—The next Fruit and Floral meeting of the Royal Horticultural Society will be held on Tuesday, April 18th, in the Drill Hall, James Street, Westminster, 1 to 5 P.M. In addition to the Society's ordinary meeting, the National Auricula and Primula Society will hold its annual show, and there will also be an exhibition of Daffodils. At three o'clock a lecture will be given on "Asparagus, Forced and Outdoors," by Mr. G. Norman, F.R.H.S.

— **LIGUE HORTICOLE L'UNION.**—The Committee of the Ligue Horticole l'Union, at the exhibition to be held at Mont St. Amand, near Ghent, has decided to offer all foreign nurserymen who may be present in Ghent during the exhibition, from the 30th of April to the 9th of May, a free entrance ticket, available for the whole time the show lasts. Those who desire a ticket should write as soon as possible to the Secretary, Ligue Horticole l'Union, Mont St. Amand, Ghent.

— **SPARROWS AND CARNATIONS.**—I have never known these mischievous birds so destructive as they have been this season. Nothing has escaped them, and they pass from one crop to another without prejudice until they come to the Carnation bed, where they revel. It is sad to see fine plants of these beautiful flowers ruined in what seems to be absolute mischief, for the leaves are not eaten, but simply picked off and thrown down. When a bed is reserved entirely for Carnations this can of course be netted, but the plants that are grown in herbaceous and mixed borders are badly cut about.—B. S. E.

— **THE GARDENERS' COMPANY.**—A meeting of the Court was held on Thursday. Mr. W. A. Bilney was admitted to the freedom and livery. A scheme for admitting members of the craft and working gardeners to the Company's freedom, and for granting trade certificates of competency on the result of an examination under the auspices of the Company, was laid before the Court by Mr. C. Welch. After considerable discussion the scheme was referred to a Committee, consisting of the Master (Sir William Farmer), Mr. N. N. Sherwood, Mr. C. Welch, and the Clerk (Mr. R. Gofton-Salmond). It was also decided, says the "City Press," to proceed with a new edition of a short account of the Company which was issued in 1890. A proposal to prepare a history of the Company and of gardening in the City of London was also favourably received, and reserved for fuller consideration. Sir William Farmer, at the close of the business, entertained the members of the Court at dinner, Mr. W. A. Bilney, the newly elected liveryman, being the guest of the evening.

— **APRIL SHOWERS.**—The considerable though steady rainfall of Sunday last has proved to be most welcome, for whatever may have been weather conditions farther north, southwards there has been very little rain since February, and the month of March, between wind and frost, had made the soil very dry on the surface. We have had a few showers in April previous to Sunday, but they were slight, and very soon dried by strong winds. Sunday was an ideal April day in its moisture; not a hard rain, but a gentle persistent downfall, that thoroughly moistened the soil, because it penetrated; none too warm, it was generally in consonance with the season. Whilst giving all early sown seeds and late planted things a good help, it should also greatly benefit the pastures, and thus render the farmer good service. Rain also as it emanates from cloud staves off frost, and as the Plums, Pears, and Cherries are fast expanding their bloom, we have little desire to see the days too bright and hot, as so often these are followed by nights of low temperature and white frosts. Many persons have assumed that because we had such heavy rainfalls in February, that enough moisture had fallen to last for months. March, however, showed us that if the air can be absorbent, so also can the soil, for every trace of excessive moisture had entirely disappeared, and rivers and streams had fallen low. A dripping April will be a great blessing to our gardens and crops.—A. D.

— **GARDENING APPOINTMENT.—CORRECTION.**—A correspondent writes:—A short time ago I wrote you that Mr. Mossop had been appointed gardener to Harvey Goodwin, Esq., Orton Hall, Westmoreland; but Mr. Mossop declined, without entering, the charge, which has been accepted by Mr. Lamb, late of Singleton Park, Kendal.

— **ROYAL METEOROLOGICAL SOCIETY.**—At the ordinary meeting of the Society, to be held at the Institute of Civil Engineers, Great George Street, Westminster, on Wednesday, the 19th inst., at 7.30 P.M., the following papers will be read:—"Soil Temperature," by Mr. Henry Mellish, F.R.Met.Soc.; "Some Phenomena Connected with the Vertical Circulation of the Atmosphere," by Major-General H. Schaw, C.B.

— **HAWFINCHES AND PEAS.**—I was pleased to see at least one good word for the hawfinch, or butcher bird, as it is termed, for, as Mr. J. Shalford says, they are beautiful creatures. I have suffered as much as most people from their depredations, and have often felt inclined to deal out rather summary justice, but so far have not killed a single bird. I think they are most numerous in the eastern midland counties; at any rate I have never seen so many of them in the West or North of England. The birds are naturally very shy, and their presence is often unexpected in the garden until the Peas are attacked. I have never seen them injure any other crop.—C. H.

— **THE DUMFRIESSHIRE AND GALLOWAY HORTICULTURAL SOCIETY.**—The prospects of the resuscitated Dumfriesshire and Galloway Horticultural Society are, in the opinion of its promoters, decidedly promising. The show is to be held in the Drill Hall, Dumfries, on September 6th. By a large majority, the Town Council of Dumfries, at a meeting on 6th inst., agreed to grant a sum, not exceeding £15, to purchase a challenge cup for the Society. It is proposed that the cup be competed for by local horticultural societies. It is proposed to hold occasional meetings for the discussion of horticultural subjects, and the exhibition of plants of interest. The inaugural lecture, one on "Daffodils," is to be given by Mr. S. Arnott, on the 18th April.

— **CORNISH POTATOES AND MARCH FROSTS.**—It is said, "He who is fastest at the start is seldom good to stay," and this appears verified this year with the early Potato planters in West Cornwall. They planted, as usual, at the latter end of January, and in February growth proceeded freely in the mild weather until the third week in March. Then there was a terrible reckoning. Whole fields, up in rows, and nearly ready to mould, were cut down with the frost and displayed a blackened wreck. Men who planted much later up country will put Potatoes on the market before Cornishmen, whose vaulting ambition has o'er-leaped itself this season.—("Rural World.")

— **EMIGRANTS' INFORMATION.**—The April circulars of the Emigrants' Information Office and the new annual editions of the penny Handbooks show the present prospects of emigration. The notice boards are now exhibited, and the circulars may be obtained free of charge, at more than 350 public libraries throughout the country. April is the best month to arrive in Canada; there is a good demand for experienced farm hands, except in British Columbia. In New South Wales, owing to the severe drought in the Western districts of the colony, and the great loss of sheep, station hands have been dispensed with, and there is consequently no demand for them. Recent reports from such widely distant parts as Walgett, Wilcannia, Mudgee, Orange, Cooma, Bourke, Jerilderie, Lithgow, Queanbeyan, Wagga Wagga, Hillstone, Dubbo, and Young state that there is practically no demand for ordinary farm or station hands. At Uralla and Grafton in the far north there is a fair demand for farm labourers and carpenters, and a good one for servants. Really skilled dairymen and thoroughly capable farm labourers would probably have little difficulty in obtaining employment in many parts of the colony. In Victoria local labour is generally sufficient, but there are excellent openings, as a rule, for farmers, dairy farmers, and fruit growers, if they have a little capital and some experience of the country. There has been a general rainfall, and a very good harvest, and the dairy industry has improved. In South Australia there is no improvement in the demand for labour. In Queensland there is a general demand throughout the colony for ploughmen and other farm labourers, and for female domestic servants. Free passages are again being given to labourers and female domestic servants, and some assistance towards their passages is also now being given to farmers, market gardeners, dairymen and fruit growers, and their families; application must be made to the Agent-General, 1, Victoria Street, London, S.W. In Western Australia there is a good demand for farm labourers in the South-West, and the mining industry continues to expand. The assisted passages to the colony have been discontinued. In Tasmania there is no general demand for more mechanics or farm labourers.

METEOROLOGICAL OBSERVATIONS AT CHISWICK.

A week of south and north-westerly gales, with some showers, and storms of rain, snow, hail, and sleet on the 8th.

— MARCH WEATHER AT DOWLAIS.—Rainfall, 2.22 inches, which fell on ten days. Greatest fall, 1.09 inch on the 25th. Total for the past quarter, 19.07 inches. Temperatures: mean maximum, 52°; highest reading, 73° on the 15th; mean minimum, 27.871°; lowest reading, 12° on the 22nd. The lowest readings we have had were on the following dates:—20th 15°, 21st 13°, 22nd 12°, 23rd 17°, 24th 16°; below freezing point on twenty-two days, amounting in the aggregate to 190° of frost. The wind was in the N.E. and E. on thirteen days, and in the S.W. and W. on ten days. There were seven sunless days. Very cold winds on the whole throughout the month.—WM. MABBOTT.

— GENETYLLIS TULIPIFERA.—In the days when many establishments boasted a cool house, which in the summer was resplendent with Azaleas, and Heaths were rarely out of bloom, the pretty Tulip-flowered Genetyllis was often to be seen. I have not met with a plant of it for some time, but think it is attractive and useful enough to be grown more. A cool greenhouse is suitable for it, and if given the same treatment as is applied to the Myrtles, to which order it belongs, the Genetyllis rarely fails to bloom freely. The Tulip-shaped flower is both pretty and graceful, and the usefulness of the plant lies chiefly in the long time which it keeps in bloom. Like most other hardwooded plants, it should be potted firmly, and it appreciates peaty soil and sand. Care with watering is also necessary, for if the plant suffers through lack of moisture, it becomes unsightly, on account of the leaves falling.—H. A.

— UNITED STATES FORESTS.—A strong effort is being made in the United States to arrest the demolition of the forests of the country, which has been proceeding at an alarming pace for a great number of years. According to a statement issued by the American Newspaper Publishers' Association, the denudation of forest land in the four States of Maine, New Hampshire, Vermont, and New York is progressing at the rate of 1700 square miles per annum. If this goes on without a check, it will not be many years before the timber supplies of the country will grow short, and this is only one point for consideration. In consequence of denuding the country of trees, it is said the level of important rivers and lakes has been steadily declining, and some of the North-Western lakes have been dried up. Another result, says the "Standard," is a decrease in the rainfall, seriously injurious to the agricultural interest.

— CHESTER PAXTON SOCIETY.—The closing meeting for the present session was held at the Grosvenor Museum on Saturday, when Mr. Robert Wakefield, Newton Hall Gardens, read a paper on "Hardy Herbaceous Flowers." Mr. Wakefield has of late years been recognised as one of the most successful cultivators of herbaceous flowers in this district, his exhibition collections invariably carrying off first honours at the local flower shows, and his paper on Saturday bore evidence of an intimate knowledge of all the best varieties of flowers in this interesting class. In the course of his remarks he gave a list of the varieties best adapted for general cultivation, making special reference to those best suited for decorative purposes. He also explained in detail the peculiar methods of cultivation some require before they can be grown to perfection. An interesting discussion followed, after which a hearty vote of thanks was accorded to Mr. Wakefield for what proved to be an interesting and instructive paper.

— POT FRUIT TREES.—When at Easthorpe, Reading, not long since, I was much impressed with the appearance of some twelve or so quite large bush Pears that were growing in 14-inch pots and standing outdoors, where practically they were shifting for themselves. The main stems were as big round as a man's arm. Each tree was some 7 feet in height, very robust, of course kept hard spurred, yet the picture of rude health, and studded all over with fruit spurs. They had been in the pots several years, getting only frequent dressings of dry artificial manure and soakings of liquid manure. It was interesting to notice how robust and productive these trees could be with such restricted root area. They had become too large for the orchard house, and will probably be plunged in the open ground for the summer.—A. D.

— BESCHORNERIA TUBIFLORA.—This is one of the most showy of the half dozen or so species cultivated in gardens, and is worthy a place either as a foliage or flowering plant. It is a native of Mexico, and has been described under the name of B. Coliniana, this name being sunk in favour of the former. On a well-grown plant the leaves are about 3 feet long, by 3½ inches wide. They are green, and beautifully striated with silvery lines, which vary considerably in width. On the young leaves the markings are very distinct, fading as they get older. When young the leaves are upright, assuming a drooping habit with age. The flowers are green, 1½ to 2 inches long, and tubular. They are borne on racemes 6 to 9 inches long, on the upper two-thirds of a scape 5½ feet high. The scape is reddish brown with a glaucous covering. At the base of each branch a rosy pink bract is produced, 6 inches long by 1½ inch wide. Taken as a whole, the bright coloured scape, and bracts with their glaucous covering and the pretty green flowers, an attractive object is made. A plant is now to be seen in flower in the Mexican house at Kew, where planted out it looks perfectly happy. A figure of this species may be seen in the "Botanical Magazine," t. 4642.—W. D.

— SOME EDIBLE FLOWERS.—To give soups a spicy odour the flowers of *Hemerocallis graminea* are used in China. Seven million pounds of these are shipped yearly from the port of Tsching-Kaing to other parts of China, besides being imported to Japan. The sweet fleshy flower heads of *Bassia latifolia* are eaten in the East Indies. They resemble little Figs or large raisins both in appearance as well as in flavour. In order to preserve them they are sun-dried, and they contain 65 per cent. sugar. They are eaten without preparation, but they can also be baked with roasted wheat kernels, or can be made into a sort of ragout. The fleshy fruits of the different kinds of the *Bassia* contain an oil which turns rancid very easily, but which retains the consistency of butter in ordinary temperature. This accounts for the popular name "Butter Tree." Coupin further mentions, says our American contemporary "Gardening," a species of *Colligonum* which is plentiful in the dry prairies of the Southern Lahore. These small trees or shrubs produce numerous small rose-red flowers, which emit a pleasant but intoxicating fragrance, similar to that of ripe Strawberries, and remind one, like those of the *Bassia*, of small dried Figs. These flowers are baked with flour or eaten with roast meat after they have been kept in stone jars at least one night.

— CINERARIAS.—Are the flowers of these plants becoming too large, and are we in danger of losing in them true quality in form and substance, because of the increase of size? When flowers measure from 4 inches to 5 inches across, surely they are not only big enough to satisfy the ambition of any grower, but are large enough to satisfy any requirements. But then what is the gain when such huge flowers result? Certainly fewer of them on a plant, and some material loss of form and substance. Blooms that range from 2½ to 3 inches across are really very large and greatly beyond the dimensions of flowers that were esteemed of the best by the old florists. However, the *Cineraria* is now hardly regarded at all as of the flowers. It is a first-rate greenhouse and conservatory plant, and very effective when well grown and of a good strain. But in the old days there were numerous good named varieties propagated from year to year through the agency of offshoots or suckers. Now we trust entirely to seed, and although there are superb varieties that have been in years past as seedlings named and certificated, still propagated in this way, yet they are not put into commerce, the plants grown ordinarily being raised from seed solely. *Cinerarias* suffer somewhat from being forced in heat, which they neither like nor need, but also from soil too rich, producing foliage of much too luxuriant form at the expense later of the flower heads, and of overpotting, which often leads to root-damping, and sometimes sudden collapse of the plants. The finest collection in the kingdom of *Cinerarias* is grown cool, never overpotted, and always shows good balance between leafage and bloom.—WANDERER.

— **READING GARDENERS' ASSOCIATION.**—"Climbers" was the title of a lecture given by Mr. J. Crooke, of Forde Abbey, Chard, on Monday evening last, when the President, Mr. C. B. Stevens, presided over a good attendance of members. In introducing the subject, Mr. Crooke said that the subject he had selected was an old and very broad one, and it also included a wide range of plants. In arrangement, the gardener should cultivate taste as well as plants, and to get away from old systems which did not lend themselves to our present day needs, also that more use should be made of our native hardy climbers. A discussion followed, in which Messrs. Woolford, Stanton, Neve, Fry, Martin, Purkis, and Townsend took part. A vote of thanks was accorded to Mr. Crooke.

— **FERTILISATION OF ARAUJIA (PHYSIANTHUS) ALBENS.**—The following reference to a recent meeting of the Linnean Society will be interesting to readers of the *Journal of Horticulture*, as it refers to a subject mentioned on page 235 by Mr. Wm. Camm of Battle Abbey. Dr. John Lowe, F.L.S., communicated some observations on the fertilisation of *Araujia albens*, a Brazilian climber, which in the South of England grows in the open air. Last summer it was blooming freely in Lord Ilchester's garden at Abbotsbury Castle, Abbotsbury, Dorsetshire, where the flowers were visited by numbers of butterflies, diurnal moths, humble bees, wasps, and large flies, many of which were captured and imprisoned for a time in the pinching-bodies (Klemm-korper of Müller). All these insects, with the exception of some humble bees in their visits to the nectar left their proboscis behind, and sometimes a leg, being not strong enough to detach the pinching-body. Dr. Lowe described the structure of the pinching-bodies, which are flat, horny plates, situated above the nectar cups, at each angle of a five-sided hollow cone in the centre of the flower, in which is placed the stigma. There is only a small opening at the apex and a narrow slit at the base of each facet of the cone. To the upper point of the pinching-body the pollinia are attached. When an insect has its proboscis caught in the slit, which narrows always to its point, it can only escape by tearing away the body with its pollen-masses, or by leaving its proboscis in the slit. In the former case it carries the pollinia to the next flower it visits, and thus effects cross-fertilisation by leaving the pollen-mass between the anther-wings, whence it rapidly passes into the cone. He had received a number of flowers of *Araujia* from Mr. Benbow, the gardener at Abbotsbury, in some of which he found the proboscis of a butterfly or moth in each of the five angles of the cone, showing the great destruction of insect life caused by the plant. Mr. N. E. Brown, A.L.S., who has made a special study of the Asclepiadaceæ, gave an interesting account of the manner in which the pollinia reach the stigma; and some further remarks were made by Mr. A. W. Bennett.

CHOISYA TERNATA.

EITHER for supplying cut flowers or for home and conservatory decoration from December to May, it would be difficult to name a more useful plant than this member of the Rutaceæ order. Introduced from Mexico as long ago as 1825, it is surprising that this nearly hardy evergreen shrub is not more generally grown, especially as it possesses the merit of being easily managed and adapting itself to all sorts of conditions.

It may be bloomed in 3-inch pots, grown into bushes 5 feet or more through, or trained into standards with a clean stem from 3 to 5 feet high, carrying heads 3 feet through. Half-ripened shoots inserted into sandy soil early in the year and kept moderately close and shady in a propagating case, can, in a temperature of 60°, with plenty of moisture, be grown into plants that will produce a large head of bloom the following spring. These will be found exceedingly useful for interspersing amongst other plants on the greenhouse or conservatory stage, or for house decoration where white flowers are appreciated.

To maintain a continuous supply for the long period mentioned, a good stock of plants is necessary, and if these, after setting their flower buds in the autumn, can be kept in a temperature of about 40°, they will remain in a quiescent state from which plants may be selected and introduced into conditions exactly suited to the forcing of Lilacs and Deutzias. The flowers are pure white with yellow anthers, resembling, individually, Orange blossom, but with a scent more like the Hawthorn. The inflorescence is a terminal, corymbose cyme, and is surrounded with dark green, glossy, ternate foliage, so that a cut spray is a small bouquet in itself, requiring no other green.

Choisya ternata is not at all particular as to soil, but taking into account that its roots may be confined to the pots or tubs for a number of years, a good fibrous loam, with a little bonemeal and enough sand to secure moderate porosity, should be selected. This plant is nearly hardy in a state of rest, but those which have made their growth under glass early in the year must not be exposed to spring frost or cold cutting winds, though after all danger of these unfavourable conditions are past the plants are best out of doors in a sheltered position until November.

To keep the plants to within given dimensions they should be pruned

every year immediately after flowering, and afterwards placed into a moist growing temperature so as to encourage a vigorous break, by which means abundance of bloom will be forthcoming the following spring.—J. H. W.

ROYAL BOTANIC SOCIETY.

APRIL 12TH.

THE spring show of this Society cannot be chronicled as other than a large trade exhibition, for there was only one competitor in the classes for professional gardeners and amateurs, and there was only one exhibitor in each of the classes open to all—a sorry state of affairs for this once flourishing Society. The trade exhibits were good, and made a good display.

Mr. G. Kelf, gardener to Mrs. Abbot, South Villa, Regent's Park, was the only exhibitor of twenty-four pots of Tulips with a good display. The best were Ophir d'Or, Vermilion Brilliant, Proserpine, Keizerskroon, White Pottebakker, and Joost Van Vondel. The same exhibitor was awarded first for a similar number of Hyacinths; the most conspicuous spikes were King of Blues, Etna, Grand Maître, Von Schiller, Chas. Dickens, and Mont Blanc. Mr. Kelf was the only exhibitor of *Azalea mollis*, staging six well-flowered plants, and was deservedly given first prize. The classes for twelve Hyacinths, twelve Tulips, and six table plants were simply a repetition of the others by the same exhibitor, who gained the same prizes. Mr. Kelf was the only exhibitor of a group of flowering and foliage plants, which was bright and effective. The majority of the subjects employed were bulbs, *Azaleas*, *Spiræas*, *Lily of the Valley*, *Azaleas*, and *Cinerarias*, grouped with *Palms*, *Caladiums*, and *A-paragus*.

Messrs. A. W. Young & Co., Stevenage, were the only exhibitors of twelve *Cinerarias*, and were awarded first prize. The same exhibitors were granted second prize for twelve *Polyanthus* with a moderate exhibit.

Messrs. B. S. Williams & Son, Upper Holloway, exhibited a group of Orchids, chiefly composed of *Vandas suavis*, s. *Gottschalk* variety, *tricolor superba* and *r. insignis*; *Cypripediums* *Boxalli nigrescens*, *Harrisianum superbum*, *giganteum* Williams' variety, and *Pit. herianum* Williams' variety; *Coelogyne Massangeana*, and *Dendrobium Pierardi*, all edged with Ferns, forming a very effective exhibit. Messrs. Wm. Paul & Son, Waltham Cross, staged a large collection of Tulips, which presented a very bright appearance. King of the Yellows, Ophir d'Or, Joost Van Vondel, Thos. Moore, Keizerskroon, Toreador, Queen of the Netherlands, Grace Darling, a colour difficult to describe, but reminds one of a shot silk; Golden Lion, Little Dorrit, and Jenny. Also some specimen plants of *Roses* *Enchantress* and *Perle d'Or* of the *Polyantha* section, a collection of spring flowering shrubs, *Cannas*, and *Camellias*, all growing in small pots, and well flowered.

Messrs. Hogg & Robertson, 22, Mary Street, Dublin, staged a collection of *Narcissi* and Tulips, about ninety varieties of *Narcissi* and forty varieties of Dutch and species of Tulips; considering the flowers had been cut since Monday, they were in excellent condition. The chief forms of *Narcissi* were Sir Watkin, Madame Klemp, Queen of Spain, Emperor, Golden Plover. The Tulips were very fine, and the most noteworthy were Thomas Moore, Californica, Grace Darling, Maes, Greigi, Eichleri, and *Chrysolora*. Messrs. Barr & Sons exhibited a capital display of *Narcissi* and *Muscari*. The most conspicuous forms were Mrs. Walter Ware, Maximus, Duke of Bedford, a giant form of *Empress*, *Horsefieldi*, Emperor, Wm. Goldring Leeds, Grand Duchess, Sir Watkin, *Triandrus albus*, M. J. Berkeley, Mad. de Graaf, Countess of Annesley. The St. George's Nursery Company, Hanwell, contributed a display of *Cyclamens*; the plants were well flowered, and the colours bright and diversified.

Messrs. Thos. S. Ware, Ltd., Tottenham, exhibited a collection of spring flowers, which comprised a collection of *Narcissi*, *Anemone pulsatilla*, *Trillium grandiflorum*, *Adonis vernalis*, *Spiræas*, *Lachenalias*, *Doronicums*, and *Primulas*. Messrs. Morle & Co., Finchley Road, exhibited a group of well grown pots of *Mignonette* of the well known market type. Messrs. John Laing & Sons, Forest Hill, contributed a display of flowering and foliage plants, consisting of *Palms*, *Dracænas*, *Crotons*, and Ferns, while the flowering section was made up of *Boronia*s, *Ericas*, *Clivias*, *Lilium longiflorum*, and a few Orchids. Messrs. Jas. Carter & Co., High Holborn, exhibited a collection of *Cinerarias*, both single and double; the flowers were large and vivid, in a wide range of colours. The double forms were dwarf in habit and of good size.

Mr. Wm. Rumsey, Joyning's Nursery, Waltham Cross, contributed a large display of cut *Roses*. The *Maréchal Niels* were a good colour, *Niphetos*, *Celine Forestier*. Mrs. Rumsey, L'Idéal, Ethel Brownlow, Gloire de Margottin, Madame Montet, Marie Van Houtte, and W. A. Richardson being very conspicuous. Messrs. J. Hill & Son, Edmonton, staged an exhibit of Ferns, the species of *Adiantums* with tinted foliage in baskets being very effective. The specimens of *Davallias* were also well developed, the whole forming a pleasing exhibit. Messrs. A. W. Young & Co. exhibited a group of *Clivias* and King of Denmark "*Geraniums*." Mr. S. Mortimer, Rowledge, Farnham, staged six boxes of *Tomatoes*, *Winter Beauty*, a seedling from *Conqueror*. The fruits were a good shape and excellent colour for the season; one box represented the bunches as grown, some carrying as many as seven ripe fruits. Two boxes of *Cucumber Sensation* were also staged by the same exhibitor.

HARDENBERGIA COMPTONIANA.

THIS hardwooded greenhouse climber makes one of the prettiest sights imaginable when well grown and flowered. It is an Australian plant, with glossy green ternate leaves. The flowers are produced during March and April. They are borne singly, or in groups of two or three, on wiry racemes 4 to 8 inches long. In colour they are violet, with two whitish blotches on the upper petal (fig. 71). It can be grown from seeds or cuttings. In the latter case half-ripened shoots should be used, 3 or 4 inches long. They ought to be inserted in sandy peat, and covered with a bell-glass until rooted. When large enough the young plants should be removed to a well drained border of peat and loam. An annual pruning must be given after flowering. When growth has recommenced water should be given liberally, with the maximum amount of air, until growth is completed in autumn. After this water should be given sparingly during winter. This, with plenty of fresh air on all suitable occasions, is all that is necessary to secure a good supply of flowers during spring.—W. D.

ROSE SHOW FIXTURES IN 1899.

- JUNE 14th (Wednesday).—York†.
 „ 24th (Saturday).—Windsor.
 „ 27th (Tuesday).—Westminster (N.R.S.).
 „ 28th (Wednesday).—Bath, Maidstone, and Croydon.
 „ 29th (Thursday).—Canterbury, Eltham, and Norwich.
 JULY 1st (Saturday).—Crystal Palace (N.R.S.).
 „ 4th (Tuesday).—Gloucester and Harrow.
 „ 5th (Wednesday).—Ealing and Hanley*.
 „ 6th (Thursday).—Co'chester (N.R.S.).
 „ 11th (Tuesday).—Hereford and Wolverhampton†.
 „ 13th (Thursday).—Brentwood and Helensburgh.
 „ 20th (Thursday).—Salterhebble.
 „ 25th (Tuesday).—Tibshelf.

* Shows lasting two days. † Shows lasting three days.

The above are all the dates definitely decided upon that have as yet reached me. I shall be glad to receive the fixtures of any Rose shows not named above, or those of any horticultural exhibitions where Roses are made a leading feature, for insertion in future lists.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

ROSES IN POTS.

ANOTHER issue of the attractive, entertaining, and useful little book entitled "Observations on the Cultivation of Roses in Pots," by Mr. William Paul, F.L.S., V.M.H., has come to our notice. Nothing more commendatory of the excellence and acceptability of the work could be advanced than is conveyed in the two simple yet forcible words, "eighth edition." The guidance given in its pages has been of great service to both amateurs and gardeners in the past, and may be in the present and the future, for the teaching is based on the best of foundations—successful experience—and is concisely and clearly imparted by a master in the art of literary exposition.

GREENHOUSE ROSES.

To grow Roses well under glass they should be cultivated as climbers, planting them out in a prepared bed or border where the roots can extend, causing free and healthy growth of wood. The latter then requires to be well ripened in order that the buds may be well matured, then it is practically certain that a crop of flowers will be produced the following season. The best Roses for indoor culture as climbers are *Maréchal Niel*, *William Allen Richardson*, *Gloire de Dijon*, *Climbing Devonensis*, and *Lamarque*. These are Tea-scented and *Noisette* Roses.

When they grow well long shoots are produced, which must be reserved at nearly their full length for flowering, the unripened ends only needing to be pruned away. After the plants have flowered is the best time for the principal pruning, and this may be carried out somewhat boldly. In the case of *Maréchal Niel* the young shoots can be shortened to a foot. Some of the weaker growths may either be cut out entirely or pruned to a few buds. The other Roses mentioned can also be freely pruned after flowering, encouraging strong and vigorous shoots.

Good compost should be provided for Roses. There is nothing better than turfy loam of a yellow colour and holding character, mixing with it some decayed manure and bonemeal, with broken charcoal to insure porosity. See that the bed or border is efficiently drained, and that the compost is healthfully moist when planting. Syringe the plants freely that they may be kept clean and free from insects, and ventilate the structure carefully.—E. D. S.

NORTHERN SPY APPLE AND AMERICAN BLIGHT

THE MARIANNA STOCK.

I HAVE on several occasions seen this Apple recommended as a stock for Apples by growers in New Zealand and Australia, and now that the subject has come before us in the columns of the *Journal of Horticulture* (page 259, March 30th), a little discussion upon it may be useful.

To begin with, I do not quite follow the arguments of Mr. Palmer, that owing to the mildness of the New Zealand climate woolly aphis is rampant. I never knew this insect injured by frost, even when it stayed above ground; but it generally goes down into the soil at the approach of winter, and hibernates upon the roots of the trees until the spring weather induces it to crawl up again. I have dug up old orchard trees during severe winter weather, and left the roots covered with aphis exposed to the frost for several days, and then found them quite lively in the midday sun. If anyone knows of American blight being killed by frost, he will do us a favour by stating the fact in your *Journal*.

I think our climate is quite as favourable as any need be to the well being of the woolly aphis, and if it flourishes in New Zealand better than it does during dry, warm summers here, I pity the cultivator who tries to be rid of it. I do not think the attacks could be worse than some I saw in my journeys last autumn through the English counties. Of course it is possible that the insects may breed more continuously in the milder climate of New Zealand, but I think very possibly that our good friend the ladybird (*Coccinella bipunctata*) may be absent, in which case the cultivators should import some, as they undoubtedly help to keep the foe in check, though I do not think they will ever clear a plantation.

I fear I have rambled from the subject of the Northern Spy, but having returned thereto, I must say that I cannot bear out your statement, Mr. Editor, that it is usually free from the attacks of American blight. It is many years now since we grew it here, and one's memory is apt to be treacherous, but I asked my foreman this morning, and he said it used to be a brute for "bug." We planted some trees of "Northern Spy" for fruiting, and they got so infested that we destroyed them. Of course that was in the old days, when "bights" were looked upon as the act of Providence, and sprayers were not used. Perhaps other growers in this country will tell us their experience with Northern Spy and the woolly aphis—that is, if they have any of either on their premises.

The only Apple which I know that is proof against the woolly aphis or American blight (*Schizoneura lanigera*) is *Duchess of Oldenburg*; only once have I seen the woolly aphis on this variety, and then it was growing in close proximity to a tree which was so full of the pest that it had probably swarmed or emigrated to find room. Of course the aphis likes some varieties better than others, but I think all the varieties I know are liable to attack except *Duchess of Oldenburg*.

I know nothing of New Zealand personally, but it is a received fact that Northern Spy is aphis proof in that climate. What I would like to know is, does the same hold good in this climate? Now, Mr. Editor, you question the fact of a stock influencing the growth of any other variety so as to make it distasteful to the aphis; but surely we need not go to New Zealand to find this out, as all cultivators know that Apples upon the *Paradise* are almost exempt from attacks, whilst those upon *Crab* will suffer severely. I daresay that I ought not to know so much about woolly aphis, and to some I may seem to give myself away by writing upon such a subject, but I have waged war with the pest for fifteen years, and know something of its habits and likes.

THE MARIANNA STOCK FOR STONE FRUITS.

A word in conclusion about the *Marianna* stock. It came from America with a great character, but we have failed to appreciate it and after four years' trial have discarded it. I happen to know that other nurserymen have tried it, for our trees were packed along with others for other nurserymen; but then, the members of our cult are so busy and so bashful. If they would record their experiments they might prove almost as useful as a Government station, which our cousins across the water enjoy.—A. H. PEARSON, *Chilwell, Notts.*

[We are much obliged to Mr. Pearson for his communication. We agree with him on two points—1, the hardness of the woolly aphis; 2, that nurserymen could, if they were not so "busy and bashful," impart valuable information on stocks and other matters. We shall now begin to differ, and rather enjoy the opportunity than otherwise, in the anticipation of something good in return.

As our friend has presented his credentials—namely, having "waged war with the aphis pest for fifteen years" (without saying who or which was the victor) it will be courteous if we present ours.

Our attack on the enemy commenced in 1846, and for three months we engaged from morning till night in, what was vainly supposed,

painting the pest out of existence. Twenty-foot stems of grand old espalier Apple trees such as are rarely seen nowadays were almost as if encased with wool. No doubt a few millions of the horrid insects were slaughtered by the mixtures, too nauseous to be named, but millions more burst out again, and nothing approaching annihilation was observable till they were treated with spirits of tar—an obsolete article for the purpose now.

The trees were on the Crab, and the younger warrior may be saying to himself, "Yes, of course, if on the Paradise they would have been almost exempt from attack." But let our able critic wait for the end—it only means a bridge of fifty-two years—and he will learn that there are exceptions to his comforting dictum, and that "all" cultivators do not accept it as unimpeachable.

their swarming foes, so the whole were burned together last December, or rather, all the trees save one; and, mark the fact, Mr. Pearson, this is on the Crab stock, of the same age as the others and planted at the same time. This tree that ought to have been the worst, according to "fifteen years' experience," was never attacked so severely as the others, and as it supports a fruiting bush of Mistletoe, its life was spared. It was not the Northern Spy, to which the pen is travelling.

But before referring to that "blight proof" variety let no one draw the inference from what has been said that we regard trees on the Paradise as more prone to infestation by the aphid in question than those on Crab stocks. We do not suggest anything of the kind. We simply consider the comparative immunity of the "Mistletoe tree" is

FIG. 71.—HARDENBERGIA COMPTONIANA.

Some years ago we planted a number of cordon Apples to cover a fence, one each of several dessert varieties, for ascertaining those most suitable for London suburban gardens. They were on the Paradise stock—at least all but one (on the Crab)—and included Duchess of Oldenburg—the alleged "woolly aphid proof" variety.

The trees were apparently clean when planted, and for a year or two afterwards. Then came the enemy. It was swept off time after time with either petroleum (in winter only), a strong solution of Gishurst, or methylated spirit, these destroying the pest in summer without injuring the trees. But it came again. After another similar battle, victory, and re-invasion, and observing no Apple trees in adjacent gardens, it was resolved to let the enemy choose its varieties and "do its worst."

It had a happy time for three years, but after killing the Margil and Cox's, and nearly finishing all the rest, including the "blight-proof" Duchess of Oldenburg (which was as white as a miller) it was thought the time had come to end the war between the trees and

due to the fact that it is a standard, with its head above the fence and exposed to all the winds that blow, while those on the Paradise that were "eaten up" by the enemy were secured to the fence and completely sheltered from the east and to a large extent from the north. This is quite sufficient to account for the difference, for, though aphid lanigera is not killed even by severe frost in winter, it rejoices in warmth in summer, and the hotter and drier the positions the greater is its rate of increase.

Whatever may be the case in open nurseries, and we readily concede that Mr. Pearson has watched the trees and their enemies there more closely than we have, as to those on the Paradise being more resistant of aphides of different forms than those on the Crab or on the free stock (which are not quite the same) we know, and have known for more than twice fifteen years, that it grown in an enclosed garden or sheltered orchard where the pest is established, trees on both stocks are liable to be infested, though not all varieties are attacked with equal persistency.

We have had trees from Chilwell both on the Paradise and Crab stock as clean and as good as we could desire to plant, but in time the enemy, lurking in established trees, took its flight to the new comers, both in orchard and garden, those the most exposed being the least infested. Reasonable shelter is good for Apple and other hardy fruit trees, but too much of it is favourable to their enemies.

In the R.H.S. gardens at Chiswick, which are almost surrounded by buildings, insects would have a happy hunting ground but for the repressive measures frequently employed. There are many varieties of Apples established on the Paradise, and several on the Crab, which, if left alone, would soon be white with the aphid in question, including the Duchess of Oldenburg, though it may not be so tempting to the pests as some others. Trees more or less weakened by bearing, or weak growers generally, seem to be attacked, as a rule, with greater determination there, or anywhere, than are the more vigorous growers.

It is doubtful if there is an Apple tree at Chiswick, no matter on what stock or of what variety, in a bearing state that would not fall a prey to the destructive pest in question if it were allowed to run its course for a couple of years. Or rather not one, except one, and that is the Northern Spy. This is never attacked. It is a standard in a bearing state (but a shy bearer). A standard of a different variety almost touching it is attacked so persistently that it had to be dressed four or five times last year, the Spy not once. It needs no insecticides, and receives none. It may be added that the American blight destroyer used there is carbolic softsoap dissolved at the rate of 4 ozs. to a gallon of water.

Mr. Pearson should see the tree for himself. It affords better evidence of its insect-resisting power than a "treacherous" memory convinces to the contrary. He admits, however, that his foreman excels him in memory—a great compliment to the foreman. Let it be said there are Apples grown under the name of Northern Spy that are not true. We have seen a few trees correct, and these were clean, but we have never yet seen a tree bear what we should call a good half crop of fruit, and we should never plant the variety for profit.

We should like our friend to raise a few stocks from the Chiswick tree, and establish some varieties that are "brutes for bug" upon them. If he should find the results equal to those in New Zealand, and show the way in starving out the woolly aphid, he would be a public benefactor, and immortalise the fine old nursery name he bears. The whole subject of his letter is important, and we have given it some attention. What will be the outcome of the venture no one knows. We can only tremblingly await results.]

FAULTS, FALLACIES, FAILURES IN FRUIT CULTURE.

DURING the past seven years I have delivered upwards of a thousand lectures in the Midlands. On three or four occasions only certain local secretaries, fond of doing things with a flourish, have announced me on the bills as "Professor." The mistake was so trivial, and of such rare occurrence, that when it came under notice it was passed over with a smile, as it might well have been by my critic. As to posing under that or any designation to which one has no right, the idea is too preposterous to be entertained for one moment, and Mr. Pearson has certainly strained a point in saying that I am so announced in Derbyshire.

It was no flight of fancy on my part about trees from the South not answering in the Midlands. The query has been put to me often enough, yet it is quite possible that Mr. Pearson has not heard of the doubt—quite as possible as the fact of his not having heard of the use of 100 tons of dung per acre before reading my article. Apart from the fact of that quantity having been used by the owner of one of the largest nurseries in this country, the important point which I was anxious to enforce is the folly of planting trees in poor soil. By far too little attention is given to this matter, and I shall indeed be well repaid if my article should induce the avoidance of line and rule, taking a more intelligent grasp of what goes to render such work successful, and the treatment of each case—soil and trees—upon its merits.

The statement that I rarely fail in my lectures to point out that trees from the South are the only ones worth having is decidedly erroneous. My advice after, or before, not in lectures, to those who require trees, is to go to nurserymen with whom fruit is a speciality. I am bound to do this, from the abominable rubbish so frequently foisted upon those who are ignorant of what is a healthy planting tree or bush. Mr. Pearson may be surprised to learn that I have sent customers to him for fruit trees; he may be still more surprised to hear that I have a goodly number of trees from the Chilwell Nurseries in my hands at the present time, many of them are pyramids, and capital trees they are too, well furnished with plenty of stout bottom growth, healthy, symmetrical, vigorous, and quite certain to become valuable fruiting trees. These are not in the County Council fruit plots, but are under my control.—EDWARD LUCKHURST.

ARTIFICIAL MANURES IN THE GARDEN.

[By Mr. A. D. Hall, and taken from the Journal of the Royal Horticultural Society.]

THE use of artificial manures in gardens is rapidly increasing, if one may judge from the number of advertisements, and the new firms that are taking to the business; and the object of the present paper is to discuss the principles that should regulate their effective and economical employment. It may of course be argued that of all places artificial manures are least wanted in a garden, inasmuch as practically perfect fruit and vegetables are grown by good cultivation with dung alone. The only question is whether the same results cannot be obtained more economically by the assistance of artificial manures, which, again, can be used to meet certain special difficulties of soil and situation in a manner that would otherwise be impossible. It must not be forgotten that artificial manures are powerful tools by which the development of the plant may be shaped by the gardener along certain directions; but, like all powerful tools, they require to be used with knowledge and discretion, or they will do as much harm as they can be made to do good.

VALUATION OF MANURES.

To learn the composition of the simple manures the gardener should refer to some book, as, for example, to Mr. Cousins' little book on the "Chemistry of the Garden," where also he will find an explanation of the proper method of arriving at the value of a manure. As to the latter an approximate way of arriving at the value of a ton of a given manure is to allow 10s. or 11s. for each per cent. of nitrogen, 1s. 3d. or 1s. 6d. for each per cent. of phosphate, or 2s. if the phosphate is soluble, and 4s. for each per cent. of potash. As an example, a manure containing 6.5 per cent. of nitrogen, 22 per cent. of phosphate, and 4 per cent. of potash is worth about £6 a ton, made up as follows: 6.5 at 11s. = 71s. 6d., 22 at 1s. 6d. = 33s., 4 at 4s. = 16s., total 120s. 6d., to which must be added a certain percentage if the manure is bought to small lots. With this preliminary knowledge of the nature and price of artificial manures, it remains to consider the specific effect of the three constituents—nitrogen, phosphoric acid, and potash—which singly, or in combination, are the essence of every manure.

EFFECTS OF MANURES.

Speaking generally, the nitrogenous manures promote growth and the vegetative development of the plant, leaf, and shoot, rather than flowers and fruit. For example, a fruit tree overdressed with nitrogen will run to wood, the leafage will be extensive and very green, the shoots will be long-jointed and soft, the buds will be wood and not fruit buds, the development of fruit will be displaced in favour of continued growth.

Of course for some vegetables it may be an advantage to promote this excessive vegetative development by the use of nitrogen, particularly in early spring, when the plant naturally finds a difficulty in obtaining supplies of nitrogen from the soil. For early crops of Cabbages, Lettuces, Peas, &c., top-dressings of nitrate of soda are a great help to rapid growth and its natural accompaniment of tenderness. Nitrogenous manures differ much in their rapidity of action; two of them, sulphate of ammonia, and especially nitrate of soda, are both extremely concentrated and immediately active; they should only be applied when the plant is growing, and several times in small quantities rather than in one application. Of course they are only partial manures, supplying but one element of plant food, and must not be used unless the land is well stocked from other sources with phosphates and potash, or else their continued application will result in the impoverishment of the soil. But in their place, and used with discretion, they are among the most powerful agents the gardener possesses.

It is, however, among the phosphates that the gardener will find his most useful manures. Speaking generally, a garden receives lavish supplies of dung, on the whole a nitrogenous manure, and is somewhat over-rich on this side, if we may judge at least from the prevalence of wood and unfruitful growth among the fruit trees of so many gardens. It is in such places, the ordinary garden which has long been receiving dung, that phosphates and little artificial manure besides, are wanted to promote a better development of flower and fruit.

Phosphates are intimately connected with the various phenomena of reproduction, which we may sum up as the maturity of the plant. Above all they are required to balance and bring to a term the growth induced by free supplies of nitrogen.

Of these bodies nothing is better for general garden use than one of the bone phosphates, bonemeal (or, better still, steamed bonemeal, as being a finer and more soluble powder), or again one of the cheap phosphatic guanos.

Basic slag is a most excellent phosphatic manure for stiff soils. It is best dug in at the rate of 6 lbs. or 8 lbs. per square rod when the land is trenched. Superphosphate is the most active of the manures

of this type, but should only be used when the soil contains naturally a fair supply of lime, on the loams and chalky soils rather than on sands or gravels or the cold clays. One or other of the manures is all but indispensable in a garden. With a supply of steamed boneflour or phosphatic guano and dung a gardener need trouble himself but little about other fertilisers.

About the effect of potash, the third of our elements of fertility, little positive is known; but in a general way it may be said that where dung is at all regularly used little is required in the way of specific potash dressings. But where dung is not employed, or where the soil is of a light sandy nature and likely to be deficient in potash, it will be necessary to apply kainit at the rate of 4 lbs. or 5 lbs. per square rod every second or third year, preferably putting it on in the winter or late autumn.

In some orchards and gardens dung cannot be obtained. In such cases it is necessary to obtain as a basis for the manuring some slowly acting nitrogenous body of an organic origin, such as meatmeal, fish guano, or rape dust, digging this into the ground at the rate of 8 lbs. to 12 lbs. per square rod in the winter. With it should go 4 lbs. to 6 lbs. per square rod of a phosphatic manure like steamed boneflour or phosphatic guano, and kainit every other year or so. Finally, as the plants are beginning to grow a little active nitrogen in the shape of sulphate of ammonia or nitrate of soda may be used along with superphosphate. The gardener working without dung should lose no opportunity of taking catch crops of Mustard or Vetches, and digging them into the soil. The land may be brought into splendid condition by heavily manuring with artificials for a crop of this sort, and turning it in a month or two before the ground is wanted again.

THE USE OF ARTIFICIAL MANURES.

A few general directions may be given for the use of artificial manures. The best returns are obtained by applying them to growing, rather than established, plants. I have seen recently planted Strawberries enormously benefited by a dressing of artificial manures that produced no sensible effect on two or three year old plants alongside. As to quantities, 1 oz. per square yard, or 2 lbs. per square rod, is equal to about 3 cwts. per acre. This may be taken as an outside quantity to use of the rich and active nitrogenous manures like sulphate of ammonia or nitrate of soda; of more slowly acting manures like the guanos, two or three times the quantity may be used.

For plants in pots it is better to use manures in solution—for example, nitrate of soda and superphosphate, or 1 oz. of sulphate of ammonia and 3 cws. of superphosphate dissolved in 10 gallons of water makes an excellent liquid manure for finishing, when buds are opening or fruit is swelling. If a compost is to be enriched, let the slowly acting forms of nitrogen, like the guanos or meat meal, be used with phosphates to correspond, and let the manure be mixed with the soil some time before the compost is wanted, for the early stages of the decomposition in the soil of these manures are injurious to tender rootlets.

PLANT ASH FALLACIES.

As to the nature of the manure required for this or that crop little can be said; the gardener has not at his service the knowledge that the farmer possesses of the specific requirements of his crops; it is only for the farm crops that systematic trials have been carried out, like the fifty-year-old experiments at Rothamsted, and the many other stations that have grown up in England and elsewhere. From these experiments and their extension by the practical experience of many years we now know with a reasonable degree of accuracy the specific requirements of each crop on the farm, whether its manure should be mainly nitrogenous or mainly phosphatic, whether potash is wanted or no: whereas we have nothing but general grounds upon which to distinguish between the requirements of a Cabbage or an Apple tree, an Onion or a Rose. It is little use analysing the plant to get this information: the proportions of nitrogen, phosphoric acid, and potash in a plant are not the proportions in which these substances should be supplied in order to best feed the plant. What is present in the smallest proportions is often the particular substance the plant most wants; it is only present in small proportions because the plant finds a special difficulty in getting it from the soil. As an instance of this common fallacy of supposing the composition of a plant's ash gives any guide to its manuring, Swedes may be taken: 1 acre of average Swedes removes from the soil 98 lbs. of nitrogen, 33 lbs. of phosphoric acid, and 149 lbs. of potash. This material would be contained in 5½ cwts. of nitrate of soda, 2½ cwts. of superphosphate, and 11 cwts. of kainit; yet the ordinary manure for Swedes, one tested by many years of experience and scores of experiments, is something like 4 cwts. of superphosphate and 1 cwt. of nitrate of soda per acre.

EXPERIMENTS.

Only actual experiments can teach us the requirements of our garden crops, and experiments of a systematic sort are few in number. We shall have in time results from the Experimental

Fruit Farm the Duke of Bedford has started at Woburn; in a commercial way we have the trials conducted by Dr. Bernard Dyer at Hadlow for the Permanent Nitrate Committee, but as yet these and other trials are young, and have not reached permanent conclusions. Meanwhile every gardener should have a little experimental plot in his own garden; he will learn much about his crops, and he will learn what no one else can teach him—i.e., the special characteristics of the soil he is working on. Such a plot costs but little trouble and becomes more valuable every year. An arrangement like the following gives perhaps the readiest information—seven plots side by side, each 1 square rod in extent:—

Plot 1, Gets no manure.

Plot 2, Gets an all-round manure. A pound of sulphate of ammonia as a top-dressing, 4 lbs. superphosphate or basic slag, according to the soil, and 2 lbs. kainit.

Plot 3, Gets an excess of nitrogen, using 3 lbs. of sulphate of ammonia instead of 1 lb., as in the previous dressing.

Plot 4, Gets no phosphate—the dressing of plot 2 without the phosphate.

Plot 5, Gets an excess of phosphate, the dressing of plot 2, with 12 lbs. of phosphate instead of 4 lbs.

Plot 6, Gets no potash, the dressing of plot 2 without the potash.

Plot 7, Gets excess of potash—the dressing of plot 2, with 6 lbs. of kainit instead of 2 lbs.

On some soils it may be well to try an eighth plot with ¼ lb. of sulphate of iron added to the dressing of plot 2.

If only a number of gardeners would put down a little trial ground of this kind, growing various crops upon it from year to year, and reporting their results to the Royal Horticultural Society, we should not long remain in our present ignorance of the specific needs of our garden plants. This paper has been confined to its particular subject—the use of artificial manures in a garden—nothing has been said about cultivation, the foundation of all gardening; nothing about dung, which may be regarded as the basis of all manuring; nothing about the use of lime: these are all points that cannot be neglected. No artificial manure will make up for slovenly cultivation, rather they demand greater care in this direction; but the object of the paper has been to indicate and explain the fact that artificial manures give additional scope to the gardener's art, and that in the hands of a skilful man they may be used to still further combat the difficulties that arise from soil or climate.

[Some time ago, during a discussion on analysis and manuring in our columns, the paper of Mr. A. D. Hall, the accomplished Principal of the South-Eastern Agricultural College at Wye, was frequently referred to. We were, in consequence, desired by some of our readers to publish Mr. Hall's paper. This we could not do at the time, but we take the substance of it now from the recently issued R.H.S. Journal, and an attractive and interesting issue it is.]

It will be observed that Mr. Hall states, "It is of little use analysing a plant to get to know its exact requirements, for what is present in the smallest proportions is often the particular substance the plant most wants, and could not obtain in larger quantity because not in the soil." Superficial so-called scientists may do worse than ponder over that pronouncement.

As to "experiments," we are disposed to think that those conducted as suggested, though interesting and instructive to the individual conductors, are not calculated to be of such general service as is indicated. In Mr. Gordon's able and comprehensive paper in the same issue of the R.H.S. Journal, he says: "When trials of manure are made, care should be taken to select land of uniform quality, for when, as sometimes happens, the experiments are conducted on lands that were cropped and manured in several different ways in the previous year, the results are, if not actually misleading, of no practical value." We should like to know what Mr. Hall thinks of that aspect of the case, which does not appear to be treated in his admirable paper.

Instead of a number of gardeners experimenting with manures on such soils as they happen to have, without definite knowledge of their manurial contents, and reporting to the R.H.S., we cannot help thinking it would be better for the R.H.S. to conduct its own experiments on a strictly scientific basis.

Though Mr. Gordon has made a strong point in the sentence above cited, it is materially discounted in his proposition that the results of County Council experiments on allotments should be reported to the R.H.S. for collation. Divergencies in soil constituents are greater on allotments than almost anywhere; the small experiments in question are conducted for the information of the allottees in the respective centres, and are of little use, because of soil variations, to outsiders. This is in accordance with Mr. Hall's proposition that if a gardener has a well conducted experimental plot "he will learn what no one else can teach him." Is not the converse of this, "and what he cannot teach anyone else who works under fundamentally different soil conditions?"

PROGRESS IN FRUIT PRODUCTION.

UNDER this heading another of the series of papers by Mr. W. E. Bear on "Flower and Fruit Farming in England" appears in the last issue of the *Journal of the Royal Agricultural Society*.^{*} The author is evidently endowed with great mental and physical activity, for he appears to have been almost everywhere and seen almost everything in most of the chief fruit growing districts in this country. Added to undoubtedly keen powers of observation he has, without doubt, another faculty highly developed—namely, that of extracting information bearing on the subject of his quest. Coupled with these qualifications is that of a facile pen, and consequently the narrative of what he has seen and heard during his wanderings is both interesting and suggestive, while it can scarcely fail to be instructive and helpful to possessors of land who desire to devote a portion of it to the cultivation of fruit, but who have little acquaintance with the subject. Though an expert agriculturist, he is a deep lover of and anxious learner in the domain of gardening, and that is, no doubt, why he asked so many questions, some of which might not have occurred to an experienced practitioner, and his voluminous report (from which we take a few extracts) will be of the greater service to the community to which it appeals.

INACCURACIES IN FRUIT ACREAGE.

On this subject we find stated: "The area under orchards in Great Britain was first given in the Agricultural Returns in 1871, when it was far from being accurate, as mentioned in the returns of the following year. As one proof of inaccuracy, it may be remarked that 23,033 acres were returned as the area of orchards in Wales in 1871. This area was reduced to 10,680 acres in 1872, and still it was far too large, as it was brought down to 3052 acres in the following year, though without a word of explanation. Probably the extent of orchards in Wales was still over-rated in 1873, as in 1878 it was returned as only 2646 acres."

Then passing over several years to the period of revival, Mr. Bear continues:—"Tabulated statements show that the totals for England and Wales have nearly doubled in the ten years that have elapsed since 1883; and probably, in reality, they have more than doubled, for corrections made in 1897 considerably reduced the small fruit area, while a slight further reduction was made in 1898, and it may be assumed that the errors in measurements then detected prevailed when the earliest return was made. In 1896 the totals were put at 69,610 acres for England, 1275 for Wales, and 5360 for Scotland, making 76,245 acres for Great Britain; while those for 1897 were 63,535 acres for England, 1043 for Wales, 5214 for Scotland, and 69,792 for Great Britain. Thus the reductions were 6075 acres for England, 232 for Wales, 146 for Scotland, and 6453 for Great Britain. The figures for 1898, as given in the table, show an apparent contraction. The number of new plantations seen in all the districts I have visited has given me a confident opinion to the effect that there has been a considerable expansion of small fruit since 1896, instead of a contraction;" and so say all of us.

AROUND LONDON.

Mr. Bear then deals with fruit growing in various districts. As an example of open air culture within fifteen miles of Charing Cross, he says:—

"Where there is scope new plantations of top and bottom fruit, or trees with flowers as bottom crops, are to be seen. One of the best of these—and no better one was inspected by me anywhere—is that belonging to Mr. Walker of Ham Common, near Richmond, the first in the Thames Valley to be visited. In addition to a considerable acreage of flowers and vegetables, Mr. Walker has 35 acres of fruit, about half Apples, one-fourth Plums, and the remaining fourth Pears. Gooseberries and Currants are grown to some extent as bottom crops, but chiefly in the rows of trees, Narcissi and Pæonies occupying most of the spaces between the rows. No Damsons, Raspberries, or Strawberries are grown. The soil is sandy; but, with the liberal treatment practised by the occupier, most varieties of fruit flourish in it admirably.

MR. WALKER'S VARIETIES.

"The principal varieties of cooking Apples, early sorts being placed first, are Lord Grosvenor, Grenadier, New Hawthornden, Stirling Castle, Bismarck, Duchess of Oldenburg (also valuable as a dessert Apple), Lane's Prince Albert and Wellington. One of the most popular Apples among market growers in some districts, and especially upon heavy soils, Bramley's Seedling, does not flourish well in the sandy soil of Ham Common; while Peasgood's Nonesuch, one of the finest and the most handsome of all cooking Apples, is not to be compared as a cropper, in Mr. Walker's opinion, with such varieties as Lord Grosvenor, Lane's Prince Albert, and Bismarck. Duchess of Oldenburg and Stirling Castle are also great croppers at Ham Common. The principal dessert Apples, in addition to the Duchess of Oldenburg, are Quarrenden, Peter the Great (otherwise

Cardinal), Worcester Pearmain, Benoni, King of the Pippins, Cox's Orange Pippin, and Yellow Ingestrie. The chief Pears are Clapp's Favourite, Williams' Bon Chrétien, Fertility, Louise Bonne of Jersey, Marie Louise d'Uccle, and Emile d'Heyst. Fertility is the variety most extensively produced, as it is a great cropper, and it comes in just after the common Hesse, which is the variety grown on the largest scale in nearly all metropolitan market orchards. Fertility is superior to Hesse, and makes a better price. Very few late Pears are grown, as Mr. Walker does not store fruit, but sends all to market as soon as it is picked. The Plums most extensively grown are Rivers' Early Prolific, Czar, Victoria, Pond's Seedling, and Monarch. The variety named first, a wonderful cropper in most parts of the country, does not yield as well as some other kinds at Ham Common, and this is also the case with Prince of Wales.

PLANTING DISTANCES AND STOCKS.

"In one great lot of Apples in the bush form on Paradise stock, planted eleven years previous to last autumn, 10 feet by 9 feet apart, it has become necessary to take out every other tree—a lamentable but necessary sacrifice of trees now in full profit. Similarly, in the case of a well-grown and perfectly healthy lot of 400 Cox's Orange Pippins (there are 200 in another place), planted six years previous to last autumn, when three years from the budding, 13 feet by 10 feet apart, every other tree is now being reduced in size by trimming, and in a few years will have to be dug up. Again, a magnificent lot of 400 Duchess of Oldenburg Apples on the Paradise stock, planted five years ago, when three years from the budding, 13 feet by 10 feet apart, are already too thick, and would have been better planted 13 feet by 13 feet. As to the distances of Plums, a lot of 400 of the Czar variety, 16 feet by 10 feet apart, and now about ten years old from the time of planting, are quite thick enough. It is a question of somewhat difficult calculation to decide whether fruit trees should be planted closely or comparatively widely. In the former case there will be some years of extra production before half the trees have to be thrown away. But where bottom fruit is grown, the balance of advantage appears to lie in planting standard Apples on the Crab or Pears on the Pear stock, 24 feet to 30 feet apart, with dwarf Apples or Pears or Plums at half distances, so that no uprooting will be necessary for about twenty years, after which the standards will cover the ground."

IN MIDDLESEX.

As a good example of the old fruit plantations of the Thames Valley, that held by Mr. Poupart of Twickenham was visited. The nursery is about 160 acres in extent, between 50 and 60 acres being devoted to fruit, and the rest to vegetables and flowers. The rows of fruit trees (mixed Plums, Apples, and Pears) are 16 feet to 18 feet apart, and the trees in the rows about 12 feet from each other. A few Cherries and a fair quantity of outdoor wall fruit are grown, but no Strawberries. Mr. Poupart sells his own produce in Covent Garden, and thus is able to make the most of it. But he does not agree with growers who think that the salesmen's usual charge of 10 per cent. on the returns is too high. On the contrary, he believes that it hardly pays, allowing for market charges and the cost of providing packages. Old orchards in the Twickenham district let at £8 to £8 10s. an acre, and land sells up to £1000 an acre, or even more in some places; but it was surprising to learn that fruit plantations in Cranford, twelve miles from Covent Garden, let in some cases for rents as high as £10 to £12 an acre, or from 25 to 50 per cent. more than the usual rents of orchards in parishes very much more populous and nearer to London.

(To be continued.)

THE GARDENERS' ORPHAN FUND.

ASSUMING that your correspondents, "S., Yorks," and "A Country Gardener," page 257, fairly represent the views of non-subscriber gardeners in relation to their objections to subscribe to the Orphan Fund, and if so, I hope the special objection put forward is a thoroughly honest one, then does it merit full attention. But all the same let it be remembered that the Orphan Fund was in existence several years before the then Secretary was granted the salary stated, and it is fair to ask how many or how few country gardeners then did subscribe; certainly they had not then this peg on which to hang an objection.

I am not at all surprised that the primary objection is the one raised, because I have heard it mentioned privately in many directions. Still it needs a good deal of courage to avow it openly, especially if the objectors did not subscribe to the Fund prior to the increase in the salary. But I would point out that, after all, the real increase was not 100 guineas, but only about 50 guineas. I remember that at the time the then Secretary elected to become a paid official, that a sum of some £50 was allowed for office expenses, the Committee practically recognising the right of the Secretary to have some compensation for the use of his house as the Fund offices. Now that the salary of 100 guineas includes the 50 guineas formerly accorded for that purpose and clerical assistance, the present Secretary has to use a portion of his London office and pay for clerical help out of the 100 guineas salary, so that his actual pecuniary recompense cannot be more than 50 guineas per annum, a fact which should be clearly understood.—A. D.

* London: John Murray, Albemarle Street.

ERICAS AND THEIR CULTURE.

GARDENERS of the past generation might well pride themselves upon their splendid achievements in connection with the culture of the many beautiful species and varieties of *Ericas*. In those days there was not so great a demand for large quantities of cut flowers, and the "rush" of the present time was not quite so pronounced, cultivators had time to study the requirements of their pet plants, time to think before they watered their giant specimens, with the result that fewer mistakes were made in watering than are apparent to-day. Fortunately, however, we have yet among us a few cultivators to whom the art of Heath-growing is not lost, but the time has come when it is necessary for a brigade of younger hands to glean from the older ones the secrets of success in this branch of gardening, then with further experience we may confidently anticipate that should *Erica* growing again become popular an army of experts may quickly be ready to take the field.

Although *Ericas* are little grown in private gardens, it is satisfactory to find that market growers are able to produce vast quantities of grand plants in 5 and 6-inch pots suitable for decorative purposes. They have evidently not lost the art of growing them to perfection in a small state, and it shows too that we live in an age when specialists are more than ever "men of mark." Let us hope that the rising generation of gardeners will grasp the opportunities of paying special attention to *Erica* culture without neglecting to acquire a sound general knowledge of their calling.

Those who contemplate making a start in growing these useful plants will do well to confine their attention for a time to the softer-wooded kinds, such as *hyemalis*, *gracilis*, *g. autumnalis*, *Wilmoreana*, and *ventricosa coccinea*, as they grow more quickly, and are not so difficult to manage as the harder-wooded ones, and after they have mastered the details of growing the former, enter with zest into the culture of the many fine varieties of *E. Aitoniana*, which include such beautiful ones as *Turnbulli* and *Barnesi*. *Austiniana*, *Cavendishiana*, *depressa*, *Devoniana*, *eximia*, *Fairriana*, *Irbyana*, and *Marnockiana*, are a few of the best among other species. The variety *propendens* (fig. 72) which recently received a first-class certificate from the Royal Horticultural Society when shown by Messrs. J. Veitch & Sons, Ltd., Chelsea, is very charming with its bright mauve flowers.

At this season plants can be obtained in small pots, which are just ready for a shift into 5-inch. During the afternoon preceeding the day on which the potting is to be done, examine the plants carefully, and water such as require it; they will then be in the right condition for potting next day, and the operator will be able to judge with a greater amount of certainty when water is again required. An inch of drainage will suffice for 5-inch pots, this to be formed of one large crock placed at the bottom and covered with pieces ranging in size from a marble to a pea. Good brown fibrous peat is a necessity; this should be pulled to pieces with the hands, and have a fourth of sharp sand added. Place some of the rougher portion of peat over the drainage, ram thoroughly, and fix the young plant in position so as to have the surface of the ball half an inch below the rim of the pot. This will allow a very thin layer of soil to be placed over the ball, and yet leave room in the pot for holding water. Be careful not to bury the stem, as deep potting has been fatal to many a hard-wooded plant.

On the other hand, do not let the centre of the old ball stand so high in the pot that water drains quickly from it to the sides, because it is then most difficult to effectually moisten the whole ball without plunging in water. Special potting sticks should be made which will fit easily into the cavity left for soil, and reach quite down to the drainage. A golden rule to observe in potting *Ericas* is always to add the soil in thin layers, press each layer well home, and make it very firm before adding another, finishing the surface by pressing as firmly as possible with the fingers or thumb. After potting place the plants in a cool house, shade from bright sunshine, and keep the front ventilators closed for a time if cold winds prevail. Damping between the pots may also be practised during dry bright weather.

About the end of May transfer the plants to cold pits, and give abundance of air, and after a time remove the lights altogether when the weather is fine. If pit room is scarce, stand the plants on a well ashed bottom in an open position, and plunge the pots to half their depth in ashes. The majority of the fine softer wooded kinds which find their way to the markets are grown on this open air system during the summer. The practice insures hard, well ripened wood and flowers in abundance.

About the middle of September place the plants under glass, in a light structure, where they can receive abundance of air on all favourable occasions throughout the winter. Give as little fire heat as possible, just enough to keep out frost; if the temperature of the house never falls below 35° no harm will result.

The harder wooded kinds of *Ericas* rarely require pruning, but the free growing ones, such as *hyemalis*, should be pruned soon after they have done flowering. Cut back the strong shoots to within an inch

or two of their base, remove the points of weaker ones, so as to give symmetry to the plants, and if the weak shoots appear crowded remove some of them entirely. I have sometimes found it beneficial to syringe the plants lightly at noon during bright weather when they are making their growth, but the practice is one which demands the exercise of judgment, or mildew will make its appearance; as soon as traces of it are visible dust the plants with sulphur, or syringe with an insecticide specially prepared.

For the production of large specimens, the healthiest and most vigorous young plants should be selected, and these must never be allowed to become root-bound until they have been placed into the largest sized pots, in which they are to be flowered. The most suitable season for potting the

majority of *Ericas* is in spring, just as young growth commences; but as many species make their growth in the summer, potting in their case should be deferred till then—in fact, each plant should be treated individually, and whatever the season, excepting late autumn and midwinter, any plant having reached that stage at which it requires more root room should be potted. As a rule, pots two sizes larger than those the plants occupy are suitable ones to use when repotting. The larger the pot the more care must be exercised in draining. A good system to follow is to place a layer of large hollow potsherds at the bottom, cover these with a layer broken moderately small, and finish off with small pieces of equal size—these allow the surplus water to pass away freely and evenly, instead of being drawn to certain points, as is the case when large crocks are placed upon the surface of the drainage.

The soil for large plants must be used in a rough state; however carefully prepared, a certain amount of fine soil always comes to hand as the work of potting proceeds; this should be placed on one side for other purposes, because, if used, it would soon become sour, and we have to bear in mind that in the production of large plants the soil employed at the early pottings must be kept sweet and tough

FIG. 72.—*ERICA PROPENDENS*

for years, if the plants are to succeed. The remarks about firm potting previously given in connection with young plants must be strictly observed when dealing with large ones, and as the work proceeds, lumps of charcoal, ranging in size from a marble to a walnut, should be introduced at intervals, for they help to keep the soil sweet, and quickly become impregnated with plant food, which is given up slowly as the roots need it. Charcoal, being practically indestructible, is of immense benefit in the culture of all large specimen plants.

Plants of small and moderate size may, with advantage, be placed in the open air during July and August, as the practice insures well ripened wood, and the abundance of fresh air circulating among them seems to have a similar effect upon them as a seaside holiday does to a human individual who lives most of the year inland—viz., it sets them up for the winter. But let us return to the plants. It is not advisable to place very large specimens in the open air, as heavy rains might ruin them, and would certainly render the work of watering a most difficult one.

Before concluding I must advance a few remarks on watering large specimens; it is an art in which proficiency can only be attained by years of experience and careful observation, and even with good training in these respects it is not everyone who can master the business, as it is necessary at the outset to be well equipped with good perceptive faculties and reasoning powers. The appearance of the surface soil and the ring of the pot do not guide us much; we must, so to speak, be able to see, or to think, through the whole mass of soil, to ascertain the exact time when water is required. When it is, give it freely, again and again till there is no doubt about every particle of soil being thoroughly moistened. Whenever there is a doubt as to whether water is required or not leave the plant for an hour, then examine it again till a decided opinion is formed; a good grower learns to decide by the appearance of the growth if water is required when other tests fail him. To water a day before it is necessary is often fatal to a valuable plant; on the other hand, many a specimen has been lost by allowing it to become dust dry to the centre before giving water; for these reasons the "golden rule" to observe is water constantly at critical times. Rain water may be termed a necessity for Erica growing, but should the supply run short during the summer expose to sun and air whatever water is used for twenty-four hours, and place in it a bag containing soot, which will help to counteract the impoverishing tendency of hard water.—PLANTSMAN.

HORTICULTURAL POSSIBILITIES IN BERMUDA.

[THE following narrative by the special correspondent of *The Times* will be read with interest. Mr. Bishop is known by many who will peruse it. He was the winner of a silver medal offered by the late Dr. Hogg for an essay on manures, and this mainly led to his nomination for the position to which he was appointed by the Colonial Secretary on the advice of Sir William Thiselton Dyer, the eminent Director of the Royal Gardens, Kew. Mr. Bishop was a persevering student as well as a sound gardener and industrious worker of high character, or he could not now be superintending the work of improvement inaugurated by the Government in "a veritable Paradise set in the balmy and brightest of seas."]

"The islands of Bermuda are built by the winds on the most northerly coral reef in the world. The prevailing and most violent winds are southerly, and thus the southern or weather edge of the reef is exposed to the more extreme action of the waves. By this action the reefs as they reached the surface have been for ages reduced to a fine coralline sand composed almost entirely of carbonate of lime. There are over a hundred islands of all sizes, but the main portion of the land is fairly continuous for some twenty miles along the weather edge of the reef.

"The inhabited and cultivated portions of Bermuda consist of low hills and gentle declivities seldom rising above 300 feet, and clothed in their native condition with the Cedar trees for which the islands are famous, but the Cedar of Bermuda is not the Cedar of Lebanon. It is, properly speaking, a species of Juniper which lacks the grace of the true Cedar, though its wood possesses the same colour and fragrance. This appears to be the indigenous growth of the islands. Their soil, however, is fertile, and when carefully cultivated with due regard to its chemical requirements, it will grow almost anything that flourishes in the same latitude in other parts of the world—a latitude south of any portion of Europe, and approximately identical with that of Madeira, of Alexandria, and of Tripoli on the coast of Africa.

"The climate is mild and singularly equable even for such a latitude, the reason being that the islands are situated on the eastern edge of the Gulf Stream, and entirely protected by its genial influence from the spells of cold which in winter chill the same latitudes on the Atlantic seaboard of the United States. The range of temperature is limited, seldom falling below 50° in winter or rising above 85° in summer, the average being about 70°. Frost is absolutely unknown, fires are a superfluity except for cooking, Strawberries ripen in January, and the first crop of young Potatoes is dug and marketed before Christmas. There is scarcely a vegetable product, native to the latitude, of any economic moment which cannot be grown to advantage in the islands, and many tropical fruits and plants might be added to the list. Bermuda arrowroot was once famous, but its cultivation appears to have been almost abandoned. The Cocanut Palm grows here and there, and a few royal Palms of stately growth may be seen in a garden on the outskirts of Hamilton. The Grape, the Olive, the Peach, the Pineapple, the Banana, the Orange, the Lemon, and many other fruits might be grown to advantage, but their cultivation appears to be entirely neglected for economic purposes and only to flourish in a few private gardens.

"Flowers are, with one important exception, only cultivated for private use and pleasure, but their variety and luxuriance is delightful. The Freesia is, as it were, the winter Daffodil of Bermuda gardens, and it flowers copiously in midwinter associated with Cannas and other semi-tropical blooms on the one hand, and with Nasturtiums and scarlet Geraniums on the other. The Poinsettia is almost a tree covered with scarlet stars, the Hibiscus and the Datura flower freely throughout the winter, the Bougainvillea grows everywhere with amazing luxuriance and exceptional depth and variety of colour, and the Oleander, growing to a height of 15 feet or more, is a hedgerow plant throughout the islands. Roses of all kinds bloom in January, but the soil is too light for their perfect cultivation.

"The agricultural industries of the islands are at present limited in extent, and indolently worked. Bermuda has never recovered the prosperity it lost when the shipbuilding industry declined. The Cedar, once its wealth, is now only its protection against the violent storms which sweep the islands. The soil requires manure, but the pasturage for cattle is scanty, the herbage consisting mainly, not of grasses, but of creeping plants, which cover the soil without making much substance. The farmers appear to be lacking in enterprise, and to be content with much smaller gains than they might make with more energy and a larger share of intelligence. But the islands exhibit no signs of poverty, and it may be inferred that their social condition is more satisfactory than their economical. The latter is very far from satisfactory, to judge from the information kindly supplied to me by Mr. George A. Bishop, F.R.H.S., the energetic and capable Superintendent of the Bermuda Public Gardens and of the Botanic Station recently established in connection with the Royal Gardens at Kew for the development of the agriculture of the islands.

"At present, apart from local requirements and supply, the agricultural exports of the islands consist almost entirely of Onions, Potatoes, and Lily bulbs. The latter is the most lucrative crop of all, the yields of an acre of well-cultivated land being as much as £480 in bulbs sent to market in New York, besides a large quantity of stock bulbs reserved for subsequent cultivation. The Bermuda or Harris Lily was introduced into the islands not many years ago and is now one of their staple products. With such a yield per acre it discourages nearly all other forms of agricultural industry, but in spite of its affinity for the soil—it is almost impossible to eradicate it when once the land has been planted with it—it rapidly deteriorates unless cultivated with care and intelligence, unless the soil in which it is grown is properly cleaned, fertilised, and well worked, and unless the bulbs used for stock are well selected and carefully cleansed from parasites and other sources of disease.

"The bulbs when matured are dug up and shipped for New York, where they are classified according to quality, and distributed to the various horticultural markets of the world. The culture is so profitable as to induce carelessness, and the yield is by no means so abundant as it might be, the soil often being left foul and the bulbs imperfectly cleansed, with the result that many crops are lost or seriously injured by blight and other forms of disease. Mr. Bishop has devoted special attention to this subject, and last year he addressed to the Board of Agriculture in Bermuda an exhaustive and most instructive 'Report on the diseases affecting the Lily in Bermuda, their cause, treatment, and prevention.' He has since supplemented this report by a series of letters addressed to the Bermuda 'Royal Gazette,' on the use and selection of fertilisers and disinfectants specially adapted to the climate, soil, and cultural industries of the islands. These investigations have aroused much interest among the Bermuda farmers, and may in time produce important results.

"Next to the Lily in importance comes the Onion, and the two are often grown side by side in alternate patches on a Bermuda farm. The crop is lucrative even at a yield of some 7 to 10 tons per acre, which is about the average, though a higher form of cultivation would, as I am informed by Mr. Bishop, enable from 24 to 36 tons per acre to be grown. The Onions are exported to New York, and the earliest are ready for market before the end of the year. Of Potatoes two crops are grown in the year—one harvested about Christmas, and the other in March.

"These are the three commercial crops of the islands, and even with a negligent culture, such as prevails at present, they are grown to great advantage, though they suffer largely from blight and other maladies which might be materially abated, if not prevented altogether, by such measures as Mr. Bishop recommends. But the farmers of Bermuda are for the most part content with such profits as the soil and climate spontaneously yield, and they are slow to adopt new methods and appliances. It is certain that by such measures as Mr. Bishop has recommended the crops of Lilies and Onions might be

largely increased, and the outlay involved might be abundantly recouped in the course of a very few seasons. New York is the chief market for Bermuda, can be reached in forty-eight hours, and the most delicate produce delivered in perfect condition.

"The cultivation of the Bermuda Lily, itself an entirely modern industry, might probably be imitated and developed in many cognate directions. 'Freesias do well here,' says Mr. Bishop in some notes with which he has kindly supplied me, 'and as much as £100 worth have been harvested from 25 rods of ground. No disease has as yet attacked the plant, though the *Eucharis* mite takes possession of any injured bulbs.' This suggests a wide variety of horticultural possibilities entirely undeveloped as yet, and seems to imply that if Bermuda were cultivated like the Channel Islands it might become a nursery of greenhouse bulbs for the whole of northern Europe and the northern regions of America. Finally, I quote the following suggestive passage from Mr. Bishop's notes:—'There are about 400 acres of waste marsh land which I think would grow the *Hevea brasiliensis*, or Para rubber. This would in the course of six years bring in the colony from £20,000 to £40,000 per year, besides greatly improving the land. This waste land is at present occupied by Mangrove swamps, unsavoury, if not positively insanitary, in their present condition and of no economical importance.

"I have so far said little of the attractions of Bermuda as a winter resort. It combines the climate of northern Morocco with something like the scenery of Denmark, though with a greater variety and intensity of colouring. The winds are often violent, but never keen, the rains are frequent and heavy, but rarely of more than a few hours' duration. English visitors in search of sunshine must cross the Atlantic to reach Bermuda. But to the people of New York and New England it is a veritable paradise set in the balmiest and brightest of seas. You may leave New York with the temperature at zero and before midnight the water of the Gulf Stream will be logged at over 70°. The first night you sleep under blankets and wear furs on deck, on the second a sheet may be too warm unless the ports can be open. On the morning of the second day you rise in an atmosphere of eternal summer, and when you land in the middle of the day you find that the lightest of summer clothing is all and almost more than you need. Thenceforth you live in a climate of surpassing softness and amid scenery of unique and varied charm. The sea is of a delicate opalescent green, shot with soft browns where the reefs approach the surface, and deepening to the hue of the sapphire beyond the outermost reefs. The beaches are of the whitest of sand, and the inner sounds are studded with innumerable islands. With such a climate and such scenery Bermuda might almost flourish on its tourist season even if Lilies failed and Onions decayed."

LIVERPOOL AMATEUR GARDENERS' ASSOCIATION.

THERE was a gratifying attendance of ladies and gentlemen at the meeting held on Thursday evening, Mr. Histed presiding. Despite the fact that rain came down in torrents, the exhibition table presented a gay appearance, quite unusual at this time of year, by reason of the fine exhibits so superior from former meetings.

Mr. R. Pinnington gave a short paper on "Orchids for Amateurs," dealing with the treatment of newly imported plants, potting, watering, shading, resting, and the popularity of Orchids in general; also giving a useful list of reasonable-priced and easily cultivated varieties.

An interesting discussion ensued, Mr. Ardran being somewhat surprised that the subject of Orchid growing amongst amateurs should be recommended on account of its costliness and the Latin names attached to many of them, and which no amateur could thoroughly grasp. He wanted to know why English names could not be substituted. Far better would it be for them to keep to such plants as *Chrysanthemums* and *Roses*, and leave Orchids alone.

Mr. Pinnington, in reply, stated that his subject had been chosen for him. In contrasting Orchids and *Chrysanthemums* he said that pretty varieties of the former could be purchased almost at the rate of bedding plants. Regarding the labour attending their culture he ventured to say that with Orchids it was not nearly so exacting or more costly than with *Chrysanthemums*. Once potted, Orchids would stand for several years with only slight top-dressing, whereas the *Chrysanthemum* was all labour. As an illustration he pointed to a small plant of *Dendrobium Wardianum* in a 4½-inch pot, carrying forty flowers and exhibited by Mr. Drake. He would like Mr. Ardran to get him a *Chrysanthemum* to give the same return. Regarding all English names, he regarded the idea as somewhat premature. To undo the works of Linnæus, Reichenbach, and others would be a labour of generations, and then would not appeal to the world as at present. He could understand some great move in the direction if the English language became universal.

Mr. Smyth supported Mr. Pinnington's remarks, and moved a vote of thanks, this being seconded by Mr. Langley and supported by Mr.

Ardran, who expressed his pleasure with the explanation given by the lecturer.

Mr. Pinnington, who is a great lover of the *Chrysanthemum* as well as of all other beauties of nature, advised them to go in for both plants.—J. M. S.

HARDY PLANTS AT EDINBURGH SHOW.

AT the spring show of the Royal Caledonian Horticultural Show on 5th and 6th April hardy plants contributed largely to the display, although they were principally from under glass. Forced hardy shrubs were very conspicuous; Azaleas were brilliant and beautiful; Deutzias were full of flower and very attractive; Japanese Maples were used with much effect in the beautifully arranged tables sent by the Edinburgh nurserymen for exhibition; Lilacs were fine; hardy Rhododendrons, Hollies, New Zealand Veronicas, and Heaths, with Aucubas, were shown in Cunningham and Fraser's exhibit; while a good plant of *Magnolia Soulangeana* made an excellent effect. Other *Magnolias* were exhibited in other tables.

The show was too early for Daffodils in the district, with the exception of those grown under glass. These were well done. Messrs. Barr and Sons' Daffodil cup, value £7 7s., was not competed for, as forty distinct varieties were required, and I understand that none of the growers in the Edinburgh district could produce these at the time. Messrs. Barr and Sons had a fine exhibit of their own. They secured a first-class certificate for their new bicolor Daffodil Duke of Bedford, and were highly commended for their novelty Apricot. Madame de Graaf, Wear-dale Perfection, Gloria Mundi, and Glory of Leiden were among the flowers in the stand. *Saxifraga Burseriana* major was also shown, and cut blooms of *Anemone pulsatilla*. Messrs. Gordon & Son, Edinburgh, had a rockery with Daffodils, Primulas, Saxifragas, and other rock plants. A novelty which received a first-class certificate was *Primula Cashmeriana* alba. *P. frondosa* was very good, and a variegated leaved *Auricula* was new to me.

There was not much competition in the class for alpiners in pots or pans. I observed good pans of *Morisia hypogaea*, *Shortia galacifolia*, *Gentiana verna*, *Primula viscosa nivalis*, and *Ramondia pyrenaica*. They had evidently been grown under glass. There were some good Primroses in pots. A few of the blue Primroses were shown, but not many of these were of good colour. Polyanthuses in pots were fairly good, but alpine and stage Auriculas would have been better a week later. *Primula Sieboldi* was well shown, but there was nothing of exceptional merit among the plants. *Astilbe* (*Spiraea astilboides*) was plentiful, and some good specimens were shown. There were a few pots of Hepaticas, with a number of Tulips and a few *Chionodoxas* and Scillas. The prizes for British Ferns did not bring out many competitors, and some surprise was expressed at the winning exhibit having included in it a Fern remarkably like *Adiantum euneatum* instead of *A. capillus-Veneris*.

There was thus, it will be seen, little of special novelty or variety, but for this the inclement season is largely responsible.—S. ARNOTT.

THE AURICULA—ITS LONGEVITY.

I HAVE frequently been asked, "How long does an Auricula live?" and the question has been before now the subject of contributions to the pages of the Journal. I do not profess to be able to give a definite reply to the query, but would merely state one or two facts bearing upon it. I can point to a plant of Prince of Greens, that I got as a very small offset from the late Mr. Meiklejohn, of Raploch, at least fourteen years ago. I have, too, what is the only plant I remember seeing at Raploch of Ashton's Bonny Lass. It is still the neat small-sized specimen of that variety that it was in Mr. Meiklejohn's collection. It came into my hands after his death, and is retained in remembrance of the old friend, to whom so very many pleasant visits were made. It has never produced an offset, and is at least eighteen years old.

But these are youngsters compared to an Auricula that the late Mr. Charles Jeffery, of Falkirk, once showed me. It was a plant of Howard's Eclipse, for which he had paid 21s. thirty-two years before. In all that time it had bloomed only twice, and had produced one offset, which was lost. The plant was given after I saw it to Mr. Meiklejohn, with whom it died a year later, thus making out at least its thirty-third year.

In fact, it would seem impossible to assign any limit to the existence of a plant, which after its last year's growth, and the shortening of its stem or carrot, is virtually a new, while still the same plant.—A NORTHERN AMATEUR.

BORDER AURICULAS.

WITH the National Auricula Society's Southern Show, due on the 18th inst., it is a good time to draw attention to those charming hardy plants, border Auriculas, because they can be so easily raised from seed, and once raised and planted out into the open ground grow so freely, and continue to do so and to bloom for many years. We have few plants so hardy as is the border Auricula. It is now a capital time to sow seed, and it can be purchased cheaply of a good and variously coloured strain. It is best to sow in shallow pans or boxes, and in sandy soil, standing them under glass, where there is a little warmth to assist germination; also keeping the soil just moist, and until the seedlings are up lightly shaded. The seeds being hard-shelled germinate irregularly, and much patience is needful.—D.

BOURNEMOUTH AND DISTRICT CHRYS- ANTHEMUM AND HORTICULTURAL SOCIETY.

THIS Society held an Exhibition of Narcissi and other spring flowers in the Shaftesbury Hall on Thursday and Friday, and is to be congratulated on the splendid exhibits brought together. With the exception of Messrs. Barr & Sons, who staged a fine collection of Narcissi not for competition, the exhibitors were all local.

In the cut bloom section the classes were all for Narcissi, and some excellent blooms were staged. All the classes were filled, and there was good competition in most of them. There were also some magnificent bouquets and epergnes of Narcissi.

In the plant section there were classes for Narcissi, Hyacinths, Tulips, Lily of the Valley, Azaleas, Spiræas, Cinerarias, Primulas, Cyclamens, and Deutzias, and amongst them were some splendid examples of cultivation. Groups of miscellaneous plants were a special feature, and the nurserymen's groups of 140 square feet were greatly admired.

The Rev. G. H. Engleheart, Appleshaw, Andover, staged some of his unnamed seedling Narcissi, two of which obtained F.C.C.'s—viz., a greatly improved form of Sir Watkin, a magnificent bloom; and also a cross between Horsefieldi and Grand Monarque Polyanthus Narcissi, showing the character of both parents. A fine bicolored Narcissi, exhibited by Messrs Barr & Sons, was named Lady Willis, in honour of the lady who opened the Exhibition.

Non-competitive groups and stands of Narcissi, floral designs, and plants helped to make up a splendid exhibition, and as such was a great success; but although Bournemouth is especially full of visitors, neither they nor the general public patronised the Show as its importance deserved.

HAILSTORM INSURANCE CORPORATION, LTD.

SUPPLEMENTARY to our reference to the annual meeting of the Nurserymen, Market Gardeners, and General Hailstorm Insurance Corporation on page 275, the Secretary sends the following interesting particulars. Mr. Harry J. Veitch presided, and there was a good attendance of shareholders. The Chairman gave some interesting figures, showing the growth of the premium income and business, as follows:—

Year.	Policies in force.	Premium Income.	Square feet covered.	Value Insured.	Claims Paid.
		£ s. d.		£ s. d.	£ s. d.
1895-6	235	681 1 9	10,408,161	135,215 16 0	283 17 4
1896-7	346	889 11 5	13,886,095	179,366 11 1	Nil.
1897-8	550	1360 17 0	20,098,104	263,590 19 1	1532 17 5
1898-9	749	1736 0 6	25,619,760	343,439 7 8	Nil.

The working expenses had been reduced from £40 10s. 3d. per cent. of the income in 1895-6, to £22 9s. per cent. in 1898-9. The whole of the cost of formation of the Corporation (£399 4s. 4d.), and of furniture (£40 7s. 8d.), has been written off. £650 had been set aside as reserve for unexpired risks.

The report was unanimously agreed to, as was the recommendation of the Directors, that a dividend of 5 per cent. for the year, and a bonus of 5 per cent. be paid; and that £200 be placed to the reserve fund, and the balance be carried forward.

At an extraordinary general meeting, held immediately after the annual general meeting, it was resolved that a further issue of 5000 shares of £5 each be made at a premium of 4s. per share, and that £1 4s. be called up between now and 1st June, 1899. This will make the subscribed capital £50,000, and the paid-up capital £10,000. The premiums on new issue will go to reserve fund.

THE YOUNG GARDENERS' DOMAIN.

THE LACHENALIA.

LACHENALIAS, by their bright, conspicuous flowers, are charming objects for the decoration of the conservatory and greenhouse during the late winter and early spring months. They are also useful for house decoration if placed in convenient sized pots, as both foliage and flowers are alike beautiful; while their long spikes of bright golden flowers are well adapted for use in a cut state. They are of comparatively easy culture, and are well worthy of a place in every garden.

The best time to pot the bulbs is the first week in August, using clean well-drained pots and a compost consisting of equal parts of good fibrous loam, spent Mushroom bed manure, and leaf soil, with a liberal addition of coarse sand. Five-inch pots are the most suitable size in which to grow them, putting eight or ten bulbs in a pot, and covering them about three-quarters of an inch deep. Stand the pots on a shelf as near the glass as possible in a cool pit, or if that is not available place them in a frame. No water will be required for some time, but they can be syringed once or twice daily according to the weather.

When the bulbs have commenced to grow admit as much air as possible on all favourable occasions, but avoid cold draughts. Those in frames should be protected from frost, while those in heated pits must not be kept too warm, or they will become drawn and weakly; a temperature of about 45° during the late autumn and winter months suits them well. When the foliage has become well developed, and the roots have taken good possession of the soil, weak liquid manure may be given once a week, increasing it in strength and the frequency of application as the plants progress. If the stock is large a succession of bloom may be had by introducing a few plants into gentle heat at intervals during the

months of December and January, but they do not respond so well to the process of forcing.

After the flowering period is over the plants should not be neglected. Place them in a light sunny position, apply water as required until the bulbs are fully matured, and when the leaves begin to turn yellow the supply of water should be gradually diminished, and finally withheld. Lachenalias, like many other Cape bulbs, require a thorough ripening and a distinct period of rest; therefore when the leaves have died off place the pots in a frame free from drip, where they may obtain the full benefit of the sun, put on the lights, and allow them to remain in that position until August, when, other conditions being favourable, they will be well ripened and rested, and ready for a restart. Lachenalia Nelsoni, a garden hybrid, is far superior to either L. aurea or L. tricolor, and appears to be the best variety in cultivation.—S. P.

[A few spikes of L. Nelsoni sent by our correspondent were in all respects excellent.]

ASTERS AND STOCKS.

ASTERS and Stocks are amongst the best outdoor flowers for the summer months. They make a good display if arranged in the beds according to their height and the colours intermixed, and are also very useful for cut bloom, especially the Comet Aster. I have seen them make a grand show when planted at the edge of a large Vine border, using dwarf Asters in the front, with a row of Stocks at the back.

The seeds may either be sown in a heated frame in rather shallow soil, or in boxes, the compost consisting of equal parts of fine loam, leaf mould, and sand. Make it moderately firm, apply water before sowing, distribute the seed thinly, and cover lightly with a similar compost, but add a little more sand. Give a thorough watering with a fine rose can, and keep them rather close until the seedlings appear above the surface. If sown in boxes a temperature of 50° at night will be found sufficient, and the boxes must be kept as close to the glass as possible.

When the seedlings are large enough they should be carefully pricked off about an inch apart in boxes, using a compost of two parts of loam to one of leaf mould, and enough sand to keep it porous. Place the boxes in a similar position to that recommended for the seed pans, and keep them close and shaded for a few days if the weather be very bright, and lightly syringe about midday. Do not at any time let the plants want for water, and when they have made a fair amount of roots they should be removed to a cooler frame, and have more fresh air, always avoiding cold draughts.

The time for placing in their flowering quarters should be about the latter end of May, so all beds and borders chosen for them must be got in readiness prior to that date; the ground must be well manured and deeply dug. Thoroughly water the plants, so that when taken out of the boxes they will have a fair amount of soil attached to the roots. Plant at a distance of 10 to 18 inches apart, according to the variety, and make the ground firm, giving a good watering to settle the soil about the roots. During the summer months, if the weather become hot and dry, the plants will require water, and if a little liquid manure can be given occasionally it will be found advantageous.—P. R.

GREVILLEA ROBUSTA.

ONE of the most beautiful and useful foliage plants is, I think, Grevillea robusta, whether required for vases in the dwelling-house or for dot plants in the conservatory. It is somewhat surprising that there are not more grown, for they really deserve a place in every garden. They are not difficult to manage, and do not demand so much care and attention as do many plants of less utility.

The greatest difficulty, so far as my experience goes, is in raising the seeds, which needs careful attention; but once the first leaf is developed after the cotyledons there is every prospect of ultimate success. The most suitable compost is fibrous loam and well decayed leaf mould rubbed through a moderately fine sieve, with the addition of a fair sprinkling of silver sand. The whole must be well mixed, and (if the seeds are sown during the winter months) it should be warmed previous to sowing. The seed pots ought to be clean and well drained, so as to allow water to pass away quickly; the soil must be pressed fairly firm. It is a good plan to dibble the seeds in rather thinly, so that when potting, each plant can be taken out with a ball of soil, and consequently with less disturbance to the tender roots. A place where they can have a good bottom heat should be chosen to encourage rapid germination.

A hand-light placed over the hot-water pipes in a vinery makes a capital propagating frame; thin roofing-slates may be used to form a bottom for the pots to stand on. If cocoa-nut fibre refuse be used to plunge the pots in, so much the better, as it holds the moisture and prevents the soil getting dry so freely. The frame may be kept constantly closed till the young plants appear above the soil, when a little air should be given to prevent the seedlings becoming drawn, gradually increasing it till they are hardened sufficiently to bear full exposure.

As soon as the plants are large enough to handle without injuring them, they may be placed in thumb pots. Care should be taken to secure as much soil attached to the roots as possible. The compost may be similar to that in which the seeds were raised, using it warm. I think (especially in regard to seedlings), many failures would be prevented if this consideration of warming the soil prior to potting were more generally practised, as a check must be given to the young roots when they come in contact with soil many degrees colder than that in which they have been growing. The plants can be replaced in the propagating frame for a few days till they begin to take hold of the new soil, when a position on a shelf near the glass should be chosen for them, to keep them sturdy.

As potting becomes necessary a slightly heavier soil should be employed

with the addition of a little bonemeal, and if at hand burnt earth; for they seem to enjoy this mixture. After potting keep them close for a short time, till they have commenced to make new roots, when plenty of air, on all favourable occasions, should be given. If the plants are required for table, 5-inch pots will be found most serviceable, with larger sizes for other purposes. Weak liquid manure given occasionally, after the pots are filled with roots, is beneficial in inducing the leaves to retain that charming shade of green in which lies, to a large degree, the beauty of *Grevillea robusta*.—ASPIRANT.

HARDY FRUIT GARDEN.

Outdoor Figs.—The pruning of old-established trees on walls or gable ends should be completed now. Old, weakly, and crowded wood must be cut out, leaving the best placed shoots and short-jointed growths. Avoid shortening any shoots that are left, as the fruit is borne at the apex of well-ripened growths of the previous year's formation. The pruning out of old wood gives an opportunity for new wood to start from buds near the main branches. These, if allowed plenty of light, air, and space, will grow sturdily, and become well ripened for fruiting the following year. They must, however, be limited in number when the buds start by careful disbudding.

Planting Young Fig Trees.—Where a warm sheltered position can be found, with the soil in a well-drained condition, and of a fertile calcareous character, young trees may be planted. Soil deficient in lime or chalk must be improved by the addition of these materials. The border need not be wider than 6 feet, and it must be made very firm, no manure added, but the surface may be mulched in summer. The present is a suitable time to prepare the site, procure the trees and plant.

Pruning and Training.—The best trees to plant are maidens having one stem. Shorten this stem after planting to 15 inches. The breaks which issue can be reduced to two of the best placed, one on each side, equal in strength and length if possible. They should be encouraged to grow strongly, as in the succeeding year two shoots must be selected from each for training as main branches. Allow plenty of space to admit of successional shoots, which will require room for training at full length. One of these ought each season to be allowed to fruit, while an adjoining shoot may be cut back to one bud. Treated thus every year there will always be fruiting shoots, and growths for succession.

Protecting Fruit Trees.—When cold, bright and frosty nights prevail, protect the blossoms of Peaches, Nectarines, and other choice fruit trees. Double or treble fish netting makes good protecting material, and as it admits light and air it may remain on the trees permanently until protection is unnecessary. However, if tiffany, canvas, or woollen netting of a small mesh is employed they must be removed when not required for protecting. Whatever material is used it ought to be placed so that it does not rest upon the branches. Slight, temporary framework of smooth wood or poles securely fixed answers the purpose best. It is only wall trees and comparatively dwarf bush or cordon trees that can be readily protected. Large standard or bush trees cannot be dealt with.

Strawberries.—Complete the planting of young plants from nursery beds. If without soil attached to the roots spread out the latter in the soil and cover carefully with a little fine material. Make the whole firm about them, but leave a little basin round each plant for holding water, which it will be necessary to afford after planting in light soil and in dry weather.

Rake off old exhausted mulching from established beds and fork up perennial weeds. A dressing of soot, 1 peck to the rod, guano 1 oz. to the square yard, or nitrate of soda, half ounce to the square yard, may be given to large established plants, sprinkling round but not immediately on the crowns. Liquid manure may be given to the plants later on. In the meantime lay down a liberal mulching of manure consisting of short and long material combined. This will afford nutriment and eventually protect the ripe fruit from dirt.

Fertilisers for Fruit Trees.—The trees which require assisting at the roots are those that grow weakly, also heavy cropping trees and bushes, which demand plenty of nutriment to assist them in developing and perfecting their fruit, as well as in making fresh wood growth. Superphosphate is an excellent stimulant to the roots, and may be applied at the rate of 3 ozs. to the square yard, pointing it into the soil. In light mould superphosphate is best mixed with half the quantity of muriate of potash. In heavy soil bonemeal is a good manure; apply $\frac{1}{4}$ cwt. to a rod of ground. The soil made black with soot, and this watered in, is good for the foliage. The various general artificial fertilisers may be employed with good effect in most cases if scattered round the bushes, forking or watering in.

Nitrate of soda and sulphate of ammonia must be used sparingly, chiefly when growth is deficient or the soil poor; 1 oz. to the square yard sprinkled on the surface as far as the roots extend is a suitable dressing. Over-manured soil rich in humus ought to be treated with lime; 1 lb. to the square yard will act upon the acid in humic matter and liberate plant food.

Dried poultry manure contains valuable constituents, but it is very strong in action, and should be mixed with six times its bulk of dry soil, and applied as a top-dressing.

Half-decomposed manure laid upon the soil over the roots of Raspberries, Gooseberries, and Currants affords nutriment as well as conserves moisture in the soil. A liberal application may be applied now to Raspberries, and to Gooseberries and Currants as soon as fruit is set and swelling. In light soil especially mulching is very essential.

FRUIT FORCING.

Cucumbers.—Good progress and grand fruit has been the exception rather than the rule, the sharp weather having had a retarding effect on the plant and that of stunting the fruit. Attend to tying out the growths, stopping one or two joints beyond the fruit, removing bad leaves and exhausted growths, so as to maintain a succession of healthy fruitful shoots. Water will be needed copiously by plants in houses, and liquid manure may be given once or twice a week with advantage. Syringe the foliage and walls daily at closing time, or about 3.30 P.M., and damp the house well in the morning and in the evening. Shade only to prevent flagging. The floor may be sprinkled occasionally with liquid manure, or fresh yet sweetened horse droppings sprinkled on the bed will answer the twofold purpose of evolving ammonia to the benefit of the foliage, and supply nutriment to the soil, as well as encouraging surface roots.

Pits and Frames.—Plants in these will not need shading as yet, but they must not be allowed to flag. Use tepid water through a fine rose watering pot at about 3 P.M., closing the lights at the same time, but as the nights are yet cold, be careful that the foliage becomes dry before dark. Close early, employing a thick covering at night, such as a double thickness of mats. Maintain a good bottom heat by linings, renewing them as necessary. Preserve a night temperature of 65° to 70°, 70° to 75° by day, 80° to 85° or 90° from sun heat, ventilating from 75°, being careful to avoid cold and drying currents of air, and close sufficiently early to run up to 90° or more. Sow seeds of ridge varieties, and keep young plants of these and other kinds near the glass.

Peaches and Nectarines.—*Earliest House.*—Discontinue syringing when the fruit commences to ripen, or it will cause the skin to crack, and impart an unpleasant flavour. It is very important to have the trees quite free from insects by the time the syringing ceases, as it must when the fruit commences ripening. If there be the least trace of red spider apply an insecticide, and follow afterwards with a forcible syringing, repeating the process if necessary, so as to thoroughly free the trees from the pest. It is only the very early Peaches (Alexander, Waterloo, Early Beatrice, and Early Louise) and Nectarines (Advance and Cardinal) that will be ripening; the others must be well syringed, and have abundant supplies of water and surface mulchings of short manure or rich material.

Second Early House.—Trees started at the new year are more advanced than usual, being accelerated by the mild and bright weather. The fruits are now stoning, and will need care in preventing checks from sudden fluctuations or depressions of temperature, that of the night being kept steady at 60°, with 5° more on mild nights, whilst on cold nights it may fall to 55°, 65° by day artificially in dull weather, 70° to 75° on cloudy days, but with clear intervals, ventilating from 70°, and freely above 75°. Attend to tying-in the shoots as they advance, and encourage no more growths than will be required for future bearing, the extension of the trees, and the swelling of the current crop. The trees must not lack moisture at the roots, affording liquid manure if they are heavily cropped and not making satisfactory growth; but avoid undue excitement to trees in full vigour, as any impulse given to growth during the stoning is apt to affect the process disastrously. Syringe twice a day in bright weather, and if necessary apply an insecticide, it being imperative that the foliage be kept clean.

Trees Started in February.—Thinning should commence when the fruits are the size of horse beans, removing the smallest and those on the under side of the shoots. Retain sufficient to admit a further thinning when they are the size of marbles, and then only a few more need be left than are required for the crop, leaving those that are best situated for receiving air and light. Disbudding must not be neglected, and laying-in growths required for next year's bearing will need careful and timely attention. Syringe the trees twice a day when the weather is bright, occasionally only when dull, and let the second syringing be at closing time or early in the afternoon, so as to have the foliage fairly dry before night. Increase the temperature to 55° or 60° at night, 60° to 65° by day, ventilating from the latter, and increasing with sun heat to 70° or 75°.

Trees Started in March.—Many more fruits have set than can possibly be brought to perfection, and an overset is a source of great weakness, often causing the fruit to be cast in showers, leaving but a scanty crop. There is no preventive but to thin the fruits as soon as it can be seen which are taking the lead in swelling, and it is better to well thin the flowers before they expand. Disbud gradually, for severe shoot removal favours growth of wood only, and sometimes gives a severe check to the fruits, causing them to drop. Syringe so as to enable the fruits to throw off the remains of the flowers, but avoid heavy syringing at this stage, as the foliage can evaporate little when wet, indeed the stomata close under water and elaboration is greatly impeded. Ventilate early and freely, so as to secure thoroughly solidified growth. A temperature of 50° to 55° will be sufficient, not allowing an advance above 65° without free ventilation.

Late Houses.—A splendid display of blossom and a grand smell of nectar characterise the trees generally in these structures. There ought

not to be anything neglected that is likely to insure the perfect fertilisation of the flowers, as without it fruit cannot attain perfection. Many of the large Peaches have large blossoms, and these sometimes have the anthers deficient of pollen. Attend, therefore, to fertilising the flowers, not trusting to insects, though bees effect the process very effectually, but they seem to be so hindered by the glass that they fight shy of fruit houses. It is not the difficulty of getting in, but of egress from the structure that bothers the bees, for when they are laden with pollen and nectar, they care about nothing but journeying homewards, and many succumb to the frantic endeavours made to take a direct flight. Secure a temperature of 50° by day, and ventilate freely, allowing an advance to 65° from sun heat. Leave a little air on constantly. Where there is a superabundance of blossom, remove all on the under side or back of the trellis or shoots, and, though this is best done before the flowers expand, it will materially aid the setting and swelling of the fruit.

In unheated houses mark 50° as the point for admitting air, and increase the amount with the advancing sun heat, not allowing an advance to or over 65° without full ventilation. Attend to fertilising the flowers, choosing the early part of fine days, always when the blossoms are fully expanded, and the pollen flying in a cloud of gold-like dust when the anthers are disturbed. There must not be any deficiency of moisture at the roots. When there is an appearance of frost, the house may be closed a little earlier, otherwise close at 50°.

THE BEE-KEEPER.

PRESENT CONDITION OF STOCKS.

WHAT is the general condition of stocks throughout the country? This is a pertinent question interesting to all bee-keepers, as a strong colony of bees at the present time will doubtless give a good account of itself when a surplus can be obtained. Since the favourable change in the weather took place, and a higher temperature has prevailed, we have been able to thoroughly overhaul the majority of the stocks in our apiary. In addition to this we have closely observed the working of the bees from other colonies. It is, therefore, satisfactory to report they are in a generally forward condition. Weak stocks are an exception, indeed we do not remember any previous year when there were so few.

What is the cause of this? We do not think it is owing to the past winter being so mild, because a year ago the winter was very similar, but the bees were not in as good condition. The two chief factors have been, first the large amount of natural stores that were left in the hives last autumn, and secondly the comparatively dry weather experienced since.

Many bee-keepers have expressed the opinion that honey which had become discoloured through an admixture of honeydew was unfit for stores for bees to winter on. The present season has exploded that fallacy, as never was honey more contaminated with it than last year, and the present good condition of stocks proves how beneficial it has been to the bees.

WEAK STOCKS.

Whether the apiary be large or small there will doubtless be many weak stocks in various parts of the country. This may be caused, as we mentioned in previous notes, from queenlessness, shortness of stores, or to the queen being old, or from some cause not visible to an ordinary observer. But whatever the cause, steps should at once be taken to remedy it. Weak stocks at this season are not likely to be of much use to the bee-keeper for storing a surplus, and there are many such in the south, judging from the numerous colonies we examined there last autumn, which, owing to the drought, were then short of stores.

We are anxious to impress on bee-keepers the necessity of having each individual stock in the apiary crowded with bees, and ready to take advantage of the honey flow when it comes. All that is required is close attention to the details of management. It is not nearly so difficult as it at first appears.

A bee-keeper may have half a dozen stocks of bees at this season, some of which are very weak. If left to take their chance little surplus will be stored. Instead, however, of keeping six colonies, reduce the number to three by uniting the three weakest stocks to the three strongest. If this rule were more generally carried out many bee-keepers, who complain of the shortness of their honey crop, would have a much better harvest in consequence, and less trouble than they had with a greater number of hives. Unity is strength, in bee-keeping as with everything else, and the greater the number of bees in a hive the better prospect there will be of obtaining a surplus.

We recommend all weak stocks to be united to the colony nearest to it. The bees need not be disturbed at this season. The old queen intended to be destroyed should first be removed and the bees in both of the hives sprinkled with flour, and the combs with the adhering bees placed alternately; cover up warm, and not a bee will be lost.—AN ENGLISH BEE-KEEPER.

TO CORRESPONDENTS

•• All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," 8, Rose Hill Road, Wandsworth, S.W., and NOT to 12, Mitre Court Chambers, Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *nom de plumes* are given for the purpose of replies.

Roses and Chrysanthemums (*Veritas*).—You ask "if these plants lend themselves, without contracting disease, to coddling treatment in the spring and summer." The answer is, Decidedly not. They will be better in the open air night and day than "coddled" in the fireless room, though a sojourn in it on possibly severe nights yet to come may be advantageous if the plants are starting freely into growth. In the summer the pots ought to be protected from the sun, either by plunging them half their depth or more in ashes, sinking them in larger pots, or shading with boards; or the roots may suffer from heat and drought, in which case insects will take possession of the leaves, and the plants produce nothing but disappointment.

Roses on Their own Roots (*E. T. H.*).—There are many Roses that will do well upon their own roots. The following twelve are equally good, and you can select the desired colours by looking through any descriptive catalogue:—Marie Van Houtte, Madame Lambard, Gloire de Dijon, G. Nabennand, Général Jacqueminot, Madame Luizet, Duke of Edinburgh, Souvenir de la Malmaison, Madame Plantier, Mrs. Bozanquet, Mrs. John Laing, and Dupuy Jamain; while all of the Mosses and Provence varieties are best when grown in this form. Cuttings of the current year's growth should be taken in September, when the wood is about two-thirds matured. At the proper season we shall probably be publishing an article upon this method of culture.

Marechal Niel Rose Casting Its Leaves (*W. S.*).—The leaflets appear to have been cast through something having cut off the supply of sap, the midrib being quite yellow at the point of junction with the petiole. This yellowish appearance has passed up some of the leaves and given rise to yellow spots, such as appear before growths of the Rose fungus, *Peronospora sparsa*, issue from them. We did not, however, find the mycelial hyphae in the yellow spots, nor any micro-organism to account for the leaflets dropping. Fumigating often causes the leaves to fall, sometimes a week or ten days afterwards, though commonly much sooner, the weather having a great deal to do with the period. If bright they fall in a day or two, and if dull weather follow they may not drop for many days after the fumigation. The solution you have watered with is rather a strong one, especially when the Rose has tender roots, as it has when making fresh growth, and this may have injured the young rootlets, hence facilitated the falling of the leaves. We can only advise a more freely ventilated atmosphere, and careful procedure in the future in both fumigation and the application of the fertiliser. There may be other reasons for the leaves falling, such as warty excrescence on the stem just below the ground, or even level with the surface, which sometimes causes the plants to lose their leaves by restricting the supply of sap.

Diseased Tomato Plant (*C. A.*).—The plant, a weak long-jointed one, had the small root fibres dead, but we did not detect any fungus at the roots, though they have the appearance of the well-known "sleepy" disease. There was, however, no trace of it in the roots, root-stem, or stem. On the leaves was a rusty appearance, especially the footstalks and midribs of the leaflets. A bit of this, under the microscope, yielded the seab fungus of the Tomato, *Cladosporium fulvum*, syn. *C. lycopersici*, and also the fertile hyphae of the fungus named *Botrytis cinerea* var. *slerotiphila*. We advise a dressing to the soil of a mixture of equal parts air-slaked chalk lime and soot by measure, two good handfuls per square yard, or a tablespoonful per pot, occasionally covering with a little soil where it is not possible to point in very lightly. Dust the plants with a powder preparation of sulphate of copper, such as anti-blight, fostite, or other advertised fungicide, applying with a bellows apparatus, and to the under side of the leaves, repeating occasionally, or about every ten days. But beyond all things give the plants more air, some constantly, moisture and closeness being very favourable to the parasites. The plants will then be made more resistant, which is the great point to aim at, securing sturdy plants from the start, and keeping them so right along, then they will be in the best condition for resisting the attacks of their enemies.

Books (F. B.).—For a book combining botany and practical gardening, you will find "Johnson's Gardeners' Dictionary," procurable from the publisher, *Journal of Horticulture*, 12, Mitre Court Chambers, Fleet Street, London, most useful. The price is 9s. 6d., post free. Sir Joseph Hooker's "Primer of Botany," which is published by Macmillans, and can be obtained through any bookseller for 1s., is excellent for a beginner in the study of botany; while for popular gardening you cannot do better than "The Garden Manual," published at 12, Mitre Court Chambers, whence it can be had post free for 1s. 9d.

Dendrobium Wardianum Malformed (*Twenty Years Subscriber*).—The flower sent is a peculiarly malformed *Dendrobium Wardianum*, the petals being entirely absent. The viscid stigma has almost disappeared, but there is pollen in plenty. It will probably appear again in the same plant, though when well established the latter may produce perfect flowers.

Pruning White Jasmine (N. B.).—Yes, it should be pruned, cutting out the dead wood, shortening foreright growth to two or three buds from the base, thinning the growths where too crowded, and shortening the long shoots required to fill space to firm well-ripened wood. This should be attended to without much further delay.

Manure for Parsley (O. F.).—Sutton's A1 manure is better than kainit, as it contains phosphoric and nitrogenic substances, as well as the properties of kainit. The 2½ per cent. of air-slaked chalk lime is easily mixed with soil, taking a hundred tablespoonfuls of the soil and adding to that amount 2½ tablespoonfuls of the lime, sprinkling on the soil and mixing thoroughly a few days before use.

Forcing Newly Planted Seakale (Idem).—The Seakale may be covered with pots the same season as planted, and the growths thus blanched be cut for use when ready. It will, however, weaken them considerably for another year, hence is not practised, especially on small planting crowns. Of course, the tops unblanched can be cooked and eaten; they are much tougher and stronger in flavour than blanched heads.

Conifer Brown (Scotland).—The small spray, evidently of some Spruce, would not be improved by thinning out the branches, unless carefully done and confined to the very weakly and partly dead or dying twigs, or small branches. This may be desirable, operating now, but avoid excessive interference with the principal side and leading growths. Give the tree a top-dressing of leaf soil thoroughly reduced or old cow manure, leaving on the surface as a mulch, about an inch thickness sufficing, and from the stem all round to the outside of the spread of the branches.

Gerbera Jamesoni (F. C.).—This plant was introduced from the Transvaal in 1889, and has occasionally been exhibited at the meetings of the Royal Horticultural Society. It is probably obtainable from several of the leading nurserymen, though it is neither widely known nor grown. It was illustrated on page 5 of the *Journal of Horticulture* for July 2nd, 1896, and of this issue we are sending you a copy.

Black Currant Twigs Infested with Mite (E. W.).—Yes, the buds are infested by the Black Currant bud gall-mite, *Phytoptus ribes*, nearly all the buds being affected. The best remedy is to cut off all the attacked shoots and burn them, or remove the galled buds, placing them at once in a pail containing some paraffin oil, the sides being smeared with it. This we have found very effectual, following with a spraying of petroleum emulsion when the bushes are quite dry. The soluble petroleum sold by nursery and seedsmen answers well, only attend to the instructions. We have not found the mite on either Red or White Currants; if you do, kindly submit specimens of affected buds.

Eradicating Coltsfoot (G. G.).—The chief thing to be attended to is draining, the land in most cases being cold and wet. The drains need not be more than 4 feet and should not be less than 3 feet in depth, placing them about 5 yards apart, and giving proper fall and outlet. This done, trench the ground as deeply as the good soil allows, and remove all the roots of the weed. Where this cannot be adopted, cut off the tops as often as they appear above ground, and persist in it from time to time, then the growth will get gradually smaller, and finally disappear. Draining, however, is the thing, together with the extraction of the roots. The draining will improve the land as well as hinder the growth of the weed.

Non-appearance of Peas above Ground (J. H. B.).—The creatures found on the Peas underground are the spotted millipede, *Julus guttatus*, which is a general feeder. The pests are harboured by vegetable matter in the ground, hence dressings of quicklime are useful. A stone of freshly burned lime, slaked with the smallest amount of water possible, and sprinkled evenly over a square rod of ground, has an excellent effect on both the land and the vermin in it, and in the course of a fortnight or three weeks a dressing of soot, one peck per rod, has a still further beneficial effect on the crop. You may use, if you like, a mixture of equal parts superphosphate (mineral 37 per cent.) and kainit, 3½ lbs. per rod, and follow with 1½ lb. of finely crushed nitrate of soda, when the plants are commencing to grow, the quantity named being for a square rod of ground, and should be applied when the plants are dry, but the ground moist. As traps there is nothing better than slices of Mangold Wurtzel, inserted here and there just within the ground or laid on this and lightly covered with short litter, examining daily and destroying the pests by removing the baits carefully and placing in hot water. Renew the baits as required, and the pests will soon be got rid of.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a

flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (C. F. W.).—1, *Sparaxis tricolor*; 2, dead. (N. B.).—1, *Polygala Dalmatiana*; 2, *Primula Reidi*; 3, *Saxifraga Boydii*; 4, *Celsia arcturus*. (B. C. C.).—Kindly read the rules given above, and pack your specimens in accordance with them. The Ferns you despatched in brown paper on Saturday were quite dead when they reached us on Monday. (C. T.).—1, *Taxus japonica*; 2, *Laurus azorica*; 3, *Gaultheria Shallon*; 4, *Cryptomeria japonica*; 5, C. Lobbi.

AMERICAN EGG COMPETITIONS.

A YEAR ago last 1st of March a movement was set on foot in England by Col. de la Bere—a kind of competitive egg production. A given number of hens were to be enclosed in a given space and fed in a given manner; a close record was to be kept of all expenses incurred and of all profits received, and the result was to be made public in March, 1899.

We have only seen one of these balance-sheets, and we were struck—1st, by the small amount put down as paid for labour

2nd, the high price obtained for the eggs; 3rd, the very slight variation in number of eggs produced in certain of the months; and, 4th, by the fact that no account whatever was taken of the food supplied to the fowls from the house. This to us seemed a serious omission. Our household is not a large one, and we think domestic affairs are economically managed, and yet every day there are many valuable odds and ends that go to greatly improve the menu of our fowls.

We have great faith in the value of house waste as fowls' food. It is generally served warm, there is variety—fat, starch, and sugar, and the pickings of bones from the stock pot are not to be despised; and yet all this is counted as of no value. We wonder what a pig-keeper would give for the waste of a gentleman's house per week? This is an item that needs consideration.

This week we have come across an account of similar trials of fowls in the States. We found it of interest to ourselves, and can only hope it may prove equally interesting to our readers. At any rate, an account of these experiments is deemed worthy of a place in the report issued by the Board of Agriculture for Kansas.

The good folks of the States have a pull over us, as food of all sorts is so wonderfully cheap, and it is the food that makes the egg. We are rather surprised to find that the first prize winners were white Plymouth Rocks. They are good birds, but we did not think they would thus come to the fore as egg producers. They are inclined in England to get a bit broody as the summer goes on, and they certainly make excellent mothers. The second prize birds were cross-bred Leghorn pullets (rosecomb brown Leghorn cock, white Leghorn pullet). The third prize went to white Plymouth Rocks. We cannot find a record of the variety that obtained fourth prize, but the fifth were all brown Leghorns, and the sixth barred Plymouth Rocks.

There were 224 entries, so one may suppose there was great variety in the breeds engaged in this contest. The eggs of all competitors were valued at the current market price obtainable in Pittsburg market. Now this seems to us a capital idea. In all competitions of this sort there should be a fixed egg value, or it is not fair to those who live far from good markets. Why should we only get 1s. for sixteen eggs in our local market when another man near a great centre sells identically the same eggs at fourteen for 1s.? There must be equality, or the test is of no value.

The first prize birds (white Plymouths) averaged 289 eggs each. These eight hens with a cockerel lived in house 12 feet by 20. The house faced south, was well built and well lighted. There was a small outside run, but during the months of December and January the birds were kept confined. They had grit and oystershell, and twice a week granulated bone. The morning meal was an equal mixture of crushed maize, oats with middlings and bran, and fine beef meal. This was served hot. For midday the ration was a little wheat, and at night maize.

As the season got warmer the morning's meal was mixed cold, and wheat took the place of maize, as being, we suppose, less heating in its nature. In the winter the house was cleaned out twice a week, in summer every day.

The second prize birds (Leghorns) produced 283 eggs, and were kept in a warm, comfortable draught-proof house. The food was very much the same as in the first example; for the sake of the exercise entailed the corn was thrown among straw, the search for hidden treasure keeping the birds occupied and amused. These birds got a certain quantity of barley and buckwheat, and milk or butter-milk. They, too, had a good supply of coal ashes and road dust for a bath, and sea shell and limestone for digestive purposes.

The first six lots of birds were curiously near in point of eggs, being respectively 289, 283, 280, 279, 277, and 262. Twenty lots of birds averaged over 200 eggs per hen per annum. We fancy these good results were brought about as much by comfortable warm quarters as by the good feeding.

Nothing thrives or does well if cold or chilled, and to see some of our fowl houses in England, one is led to ask, What redeeming feature have they? Cold, draughty, dark, and therefore dirty. Any

place seems to do for hens—tiles off, doors unhinged, and general discomfort. We do not believe in pampering, but we do believe in a little comfort and cleanliness; some place where in cold, wet weather the poor things may stand the chance of a good dry dust bath, where all the food eaten need not be used up just to keep a little warmth in the poor shivering frame. A box of grit or flints to help in mastication, and some lime or mortar scraps to provide material for the egg-shell is valuable. A warm morning's meal is not difficult to attain; a saucepan of boiling water will mix up a good deal of meal, and make a very comforting dish. We enlist the sympathies of the kitchen deity, who if propitiated can do much in the way of saving scraps of fat and skin, and so on, from plates and dishes. It is wonderful how bits will accumulate, and how valuable all those bits are no one but an ardent poultry man knows.

Warmth, cleanliness, variety in food are the main factors in egg production, but remember that as every dog has his day, so has every hen, and it is only the young and lusty that will fill the egg basket.

Sentiment must have no place in the hen yard; it is a case of the survival of the fittest, and the old must make way for the young. A hen's life of usefulness is short; with proper preparation she may make on her owner's dinner table a good end to a useful life.

WORK ON THE HOME FARM.

The cold snap is over and almost forgotten, its effect on farm work having been almost nil, for drilling was well up to date, and can now be quickly finished. Turnips are almost if not quite consumed, exceptionally so, and there is nothing to hinder a very early completion of spring sowing. This is as it should be, for although late-sown Barley occasionally does well, the chances are strongly in favour of that sown before old Lady Day.

Cattle are being gradually hardened, but the weather is quite cold enough for them, and with plenty of straw and hay for them there is no necessity to run risks, as grass has still to grow. Sheep prices are better for the milder weather, but the movement is a slow one.

Everyone complains of the seed pastures having gone off, and it is not surprising, for where they were stocked, and early stocking has been very general this spring, every animal during the frost would be carrying five mouths instead of one.

Spring tares sown now will come in very useful about harvest time for the horses, or any time they may be ready for the dairy cows. Grass diminishes both in quantity and quality after midsummer, and the tares, which are not much affected by dry weather when they have once got a start, are invaluable during a drought. They must be well treated, and there is nothing for them like good spit muck. It does not matter whether they are drilled or sown broadcast, as long as they are well covered.

Rooks have been more troublesome than usual on the early sown Barley, perhaps because it has been slow in coming up. They have also been a great nuisance about the home yards, having taken very seriously to stealing eggs. Shooting a few malefactors and hanging them in chains has apparently little effect; we shall perhaps try the effect of a dead one or two placed in traps, as if caught therein. This has been previously tried in corn fields with success.

2nd.—Fair, but almost sunless.

3rd.—Slight rain in small hours; overcast morning; occasional sun after.

4th.—Overcast day, with rain from noon to 3 P.M.; fine night.

5th.—Brilliant early; sunny morning; cloudy afternoon; rain from 11 P.M.

6th.—Rain till 1 A.M.; generally sunny in morning; showery from 3 P.M.

7th.—Gale all day, with frequent heavy showers, and an occasional gleam of sun.

8th.—Brilliant early; wild day; shower of large conical hailballs at 10.5 A.M., many exceeding quarter of an inch in diameter; rain and snow at 0.25 P.M.; heavy rain and snow at 2.45 P.M., and other showers.

A mild and rainy week, with little sunshine; the latter part stormy.—G. J. SYMONS.

BARR'S GOLD MEDAL DAFFODILS The Most Lovely of all Spring Flowers.

VISITORS INVITED

To see the Grand Display of

DAFFODILS

NOW IN BLOOM

AT

Barr's Nurseries

LONG DITTON, SURREY.

BARR'S NURSERIES are reached from London by the L. & S.W. Ry. to Surbiton Station, and from thence a short walk past the New Recreation Grounds, or cab to Pound Farm Entrance (cab fare, 1/-).

Visitors invited to see the DAFFODILS in flower, April; TULIPS in flower, May; other HARDY FLOWERS, "The Year Round."

A CONSTANT DISPLAY OF DAFFODILS

Is also maintained during April at

12 & 13 KING ST., COVENT GARDEN, LONDON**VISITORS INVITED.****ORCHIDS! ORCHIDS!**

No. 982.—VOL. XXXVIII., THIRD SERIES.

**SPECIAL SPRING OFFER
OF
BULBOUS PLANTS.**

Gladiolus Gandavensis.—In the finest and most distinct varieties of the most celebrated English, American, and French raisers, 2/6, 3/6, 4/-, and 6/- per dozen.
Gladiolus Gandavensis, "Snow White."—The most vigorous and one of the best, 6/6 per dozen.
Gladiolus Colvilli, "The Bride."—Pure white, fine for cutting, 1/9 per 100.
Gladiolus Colvilli Roseus.—Very rare. Flowers bright rose, fine for bedding or cutting, 2/6 per dozen.
Gladiolus Lemoinei.—Bright coloured and large flowering, in best older and newer varieties, 3/-, 5/-, 9/-, 12/-, and 18/- per dozen.
Gladiolus Lemoinei.—Mixed Seedlings, raised of the best named sorts, fine mixture, 1/- per dozen; 6/- per 100.
Gladiolus Lemoinei, "Marie Lemoine."—Bright yellow and crimson, 9d. per dozen; 5/6 per 100.
Crocus Imperialis.—Large bright orange-scarlet flowers, very rare, 1/3 each; 12/- per dozen.
Amaryllis Formosissima.—Flowers bright crimson. In spring, 6d. each; 4/- per dozen.
Amaryllis.—Hybrid Seedlings of one of the best raisers of this beautiful class, 1/6 each; 15/- per dozen.
Ismene Calathina (Pancratium).—Pure white flowers, fine for pots and cutting, 6d. each; 5/- per dozen.
Tigridias.—In all the best and most distinct varieties, including Alba, Speciosa, Canariensis, Wheeleri, Lilacea, Rosea, Conchiflora, Immaculata, 1/6 to 3/- per dozen.
Lilium Auratum.—Dormant bulbs, according to size, 3/-, 5/-, 6/-, 9/-, 12/-, and 18/- per dozen.
Lilium Giganteum.—Splendid bulbs, 5/-, 7/6, and 10/6 each.
Lilium Speciosum Kraetzeri.—The best of this class, 6/- per dozen.
Lilium Speciosum Purpureum.—Purplish-rose and white, 6/- per dozen.
Lilium Speciosum Rubrum and Roseum.—5/- per doz.
Lilium Sulphureum.—Sulphury-yellow, exterior rosy-purple; flowering in autumn; 2/6, 3/6, and 5/- each.
Lilium Napalense.—Bright yellow, tinged sea-green, splashed vinous purple, 2/6, 3/6, and 5/- each.
We are the only firm who can supply complete Collections of Lilies, many of which can still be planted. See our Catalogue. 12 in 6 varieties for 7/6; 12 in 12 varieties from 10/- to 20/-.

THOS. S. WARE, Ltd.,

Hale Farm Nurseries,

TOTTENHAM, LONDON.

CARNATIONS.—BORDER CARNATIONS, in 20 fine named varieties 5/- per doz., 35/- per 100, carriage paid and package free for cash with order Catalogue (150 pages) free.
JOHN FORBES, Nurseryman, Hawick, Scotland.

SPARAGUS.—This delicious vegetable does not require half the expense usually incurred. For simple instructions see SEED LIST, free on application. Strong roots from 2/6 per 100.—RICHARD SMITH & CO., Nurserymen and Seed Merchants, Worcester.

HOLLYHOCKS. For the best collection of finest named HOLLYHOCKS extant, see Forbes' catalogue (150 pages) free on application.—JOHN FORBES, Nurseryman, Hawick, Scotland.

COTTAGE GARDENING; being an Essay to which the Royal Horticultural Society awarded Mr. W. EGERTON HUBBARD'S Prize, February 16th, 1870. By E. W. BADGER. Third Edition. Price 3d.; post free, 3½d. JOURNAL OF HORTICULTURE OFFICE, 12, MITRE COURT CHAMBERS, FLEET STREET, E.C.

FORMICACIDE ANT DESTROYER.—Effectually destroys Ants in Greenhouses and elsewhere; sold in Bottles, 1/-, 1/6, and 4/-.—CORY & CO., Ltd., Finsbury Street, London. To be obtained of all Seedsmen.

PURE WOOD CHARCOAL, Specially Prepared for Horticultural use. Extract from the *Journal of Horticulture*: "Charcoal is invaluable as a manurial agent; each little piece is a pantry full of the good things of this life. There is no cultivated plant which is not benefited by having Charcoal applied to the soil in which it is rooted." DAHLIA ANALYSIS.

TO a moisture loving plant like the Dahlia the drought of last year proved extremely trying. The dry weather was of no ordinary character. Indeed, over the greater part of England the drought as affecting vegetation generally may be said to have lasted from the beginning of June until the middle of October, or for nearly the whole period of the Dahlia's existence above ground. It need, therefore, be no matter for surprise that the show held by the National Dahlia Society at the Crystal Palace last year was not so extensive as that of the previous year—the record exhibition of the series. Notwithstanding all the drawbacks of the season, which in some instances prevented exhibitors putting in an appearance at the show, the display was a very creditable one, and the number of exhibits in most of the sections compares very favourably with that at the generality of recent exhibitions.

The Shows and Fancies taken together were more numerous staged than at any of the five previous exhibitions, with the exception of those held in 1894 and 1897. On the other hand the Pompons were decidedly below average, while the Singles were in better form than in any year since 1894. The Cactus Dahlias proved, however, the feature of the show, the number of bunches exhibited having risen in the last three years from 220 to 577—the greatest number yet staged, and twice as many as at any previous show, except that of 1897.

The short table which follows will give as usual the number of blooms or bunches set up in competition at the National Dahlia Society's exhibitions in each of the five sections into which Dahlias are now divided:—

	1894	1895	1896	1897	1898
Shows (No. of blooms)	894	827	798	930	838
Fancies	301	287	276	312	305
Pompons (No. of bunches)	192	210	192	234	190
Cactus	246	280	220	432	577
Singles	138	102	126	116	131

In the foregoing statement the number of flowers staged in the classes set apart for three or more blooms of any one variety is not included.

No. 2638.—VOL. C., OLD SERIES.

When I first began these Dahlia analyses I was under the impression that the greater the number of exhibitions for which I had records available the more trustworthy would be the averages obtained, and therefore the more accurately could the different varieties be placed in the tables. But after a time I began to see that with very few exceptions it would not do to compare the doings of any one variety for an unlimited number of years if the best and most comparable results were to be obtained. For not only do even the choicest established varieties, as will be seen later on, vary in the estimation of exhibitors as time goes on, but the claims of the new comers, with their shorter records, have also to be considered. In the present analysis all the varieties in the Show and Fancy tables which will allow of this being done, and they comprise more than half the Show varieties in the table, depend for their positions upon their average records for the last eight exhibitions.

For the thirteenth year in succession Mrs. Gladstone heads the list of Show Dahlias. This grand variety has not been, however, so frequently staged in recent years as it was formerly, the average number of times it was set up at the last six exhibitions being thirty-one, against forty-one at the previous six shows. Moreover, only once before since it was first largely exhibited in 1886 has it been as indifferently shown as it was last year; but notwithstanding this decline in favour in recent years, and notwithstanding its poor appearance in 1898, there was no other Show Dahlia to be seen at the last exhibition in as many stands. R. T. Rawlings, the only possible rival to the leading flower, was also indifferently represented. John Walker, too, was not nearly as often staged as usual—in fact, there were but few varieties in this section which appeared in exceptional force. Among these may be mentioned J. T. West, William Powell, Arthur Ocock, Victor, Goldfinder, and Crimson King. On the other hand, the following sorts were not only less frequently staged than usual, but have never before been as sparsely shown at any of the last eight exhibitions:—R. T. Rawlings, W. Rawlings, Colonist, Willie Garratt, Harrison Weir, Shirley Hibberd, Mrs. Morgan, and Prince Bismarck.

In looking through my working tables of comparative records, which now covers the last sixteen National Dahlia Shows, it is interesting to notice how certain varieties become less popular as exhibition flowers as years go on, while a few others either remain stationary, or have been in recent years rather more frequently shown than they were in the early half of the period. I, of course, refer here only to varieties which have been in general cultivation throughout the whole of the sixteen years. Taking, first, those Show

Dahlias which may be regarded as decidedly on the down grade. Among these must be included Henry Walton (1873), Prince of Denmark (1881), Hon. Mrs. P. Wyndham (1881), Goldfinder (1881), Burgundy (1877), John Standish (1872), and Prince Bismarck (1879); while James Cocker (1871), Ethel Britton (1880), and Shirley Hibberd (1881) are nearly as largely grown as formerly. William Rawlings (1881) stands out as unique in that, although sent out as early as 1881, it has been staged more frequently in recent years than formerly, the exact figures being an average of twenty-three times for the last eight years, as compared with twenty-one times for the eight previous exhibitions. How few other florists' flowers are there which will bear a similar examination to the foregoing—taking into consideration the number of varieties mentioned and the length of time over which their records extend.

The progress made in this section is not so great as formerly. For instance, going back six years there are only nine sorts on the list which are less than seven years old, and of these only three find places among the first twenty-five varieties. Of the nine sorts in question, Virginale, sent out in 1893, has risen since last year from No. 48 to No. 39, while Mrs. Morgan, of the same year, has fallen from No. 35 to No. 43. Among the 1894 varieties is found the most promising of all the newer Show Dahlias—Duchess of York. It has not improved on the good position (No. 7) it secured in the previous analysis, but, on the other hand, at each of the last three exhibitions there were only four other sorts as frequently shown. Warrior, another 1894 variety, on its first appearance in the table, secures a place at No. 29, while Chieftain (No. 30) was not quite as well represented as in the previous year. The only 1895 Show Dahlia, Shotesham Hero, no doubt owing to the adverse character of the season, was only staged in seven stands, as compared with eighteen in 1897. The 1896 varieties, considering their youth, already occupy very good positions, Florence Tranter having risen since last year from No. 27 to No. 19 while Dr. Keynes makes its début at No. 26. The only 1897 variety in the table, Daniel Cornish, secures a place at No. 50.

Turning next to the Fancies, we still find that remarkable variety Rev. J. B. M. Camm at the head of the poll. In 1897, although then in its twenty-fifth year, it not only distanced all other competitors, but was to be seen in more stands than at any other show in the sixteen years. At the first eight exhibitions during that period it was staged on an average fifteen times, and at the last eight twenty-one times—which certainly indicates an unusually vigorous constitution, as well as a decided rise than a decline in favour—at all events from an exhibitor's point of view. It was, however, not quite in such

18	5.5	7	Dazzler	1893	Keynes	Yellow, striped scarlet

* A new variety, the position of which is dependent on its record for the 1898 show only.

good form as usual in 1898. The most successful Fancy last year was Duchess of Albany, which was shown in five more stands than any other variety in this section, and, with two exceptions, Mrs. Gladstone and J. T. West, more frequently than any other Show or Fancy Dahlia in the exhibition. The only other established sorts unusually well represented at that Show were Buffalo Bill, Peacock, and Dandy. On the contrary, the following four varieties, Matthew Campbell, Frank Pearce, Comedian, and George Barnes, have never before been as seldom seen.

There are, as usual, but few new or comparatively new sorts in this section. Going back six years the best placed is Emin Pasha, sent out in 1894, which has risen since last year from No. 11 to No. 10; Goldsmith, an 1895 variety, makes its first appearance in the table at No. 13; while S. Mortimer (1894) and Dazzler (1893) remain respectively as before at No. 14 and No. 18.

In dealing with the Pompons, it will not do to take as long an average as eight years, as we have done with the Shows and Fancies, as the changes in this section are so much greater. Therefore, in arranging the varieties in the select lists which follow, the different

sorts are placed in the order of their respective performances at the last four exhibitions, the newer kinds finding places according to their records at the last exhibition only. The established kinds, which were better represented at the last show than at any of the previous three exhibitions, were Bacchus, Tommy Keith, and Whisper, while Phoebe and Sunshine have never before been as poorly shown. The following varieties, arranged in their order of merit, have proved very dependable and consistent in their records throughout the four years—viz., Bacchus, Tommy Keith, Arthur West, G. Brinckman, Captain Boyton, Whisper, Eurydice, Lilian, White Aster (Guiding Star), and Isabel. Of the newer Pompons the following were as well shown as at the previous exhibition:—Sunny Daybreak (1895), Nerissa, Douglas, and Rosebud (1896).

There is at last some indication of a little more stability in the Cactus Dahlia section, nevertheless the changes are still so great, and there are so many new sorts, that I have thought it best to arrange the varieties in the select list according to their records for the last exhibition only. It may, however, be interesting to many growers to have the different sorts in that list arranged according to their

* New varieties, the positions of which are dependent on their records at the 1898 show only.

relative positions in the series under the years of their introduction. 1894, Lady Penzance, Matchless, and Gloriosa; 1895, Earl of Pembroke, Harmony, Mrs. Barnes, Mrs. A. Beck; 1896, Fusilier, Beatrice, Mrs. Wilson Noble, Miss A. Nightingale, J. E. Frewer, Mrs. Montefiore, Miss A. Jones; 1897, Starfish, Cycle, Charles Woodbridge, Cinderella, Harry Stredwick, Fantasy; 1898, Mary Service, Keynes' White, Night, Arachne, Britannia, Island Queen, Alfred Vasey, Regulus, Casilda, and Daffodil.

In the Single flowered section the positions of all the varieties, except the newer ones, are dependent upon their average records for the last three exhibitions.

The varieties in the following select lists which are marked with an asterisk are sorts sent out in 1897 or subsequently.

POMPONS.—Bacchus, Nerissa, Tommy Keith, Dr. Jim,* Arthur West, Phoebe, Captain Boyton, G. Brinckman, Whisper, Emily Hopper, E. F. Juuker, Sunny Daybreak, Eurydice, Douglas, Lillian, Orpheus*, Rosebud, Ganymede,* Sunshine, Mars, White Aster (Guiding Star), and Isabel.

CACTUS.—Starfish,* Cycle,* Lady Penzance, Fusilier, Beatrice, Earl of Pembroke, Mary Service,* Mrs. Wilson Noble, Harmony, Keynes' White,* Charles Woodbridge,* Cinderella,* Matchless, Night,* Arachne,* Harry Stredwick,* Britannia,* Miss A. Nightingale, Mrs. Barnes, Gloriosa, Island Queen,* Mrs. A. Beck, Alfred Vasey,* Fantasy, J. E. Frewer, Mrs. Montefiore, Regulus,* Casilda,* Daffodil,* and Miss A. Jones.

SINGLES.—Victoria, Polly Eccles,* W. C. Harvey, Demon, Naomi Tighe,* Miss Roberts, Phyllis, Beauty's Eye, Northern Star, Folly,* Jeanette,* Alice Seale, Jack Sheppard, The Bride, Amos Perry, Formosa, May Sharpe, Miss Glasscock, James Scobie, Guliehna, and Miss Henshaw.—E. M., *Berkhamsted*.

STOCKS FOR FRUIT TREES.

THE subject of the stocks that the various fruits are worked on, and on which so much depends for success in fruit culture, is a matter admitting of a great amount of controversy, and wide divergence of opinions may be expressed by practical men in the effort to solve the problem—of what particular varieties of fruits to work on certain stocks for producing the best all round results in productiveness and vitality.

We will take the Apple first, of which there are only two stocks in general commercial use in this country—i.e., the Crab and Paradise, commonly known as the Free and the Dwarfing stock; but in France they also use the Doucin, the French Paradise (Pommier de Paradis), and the Jeanne de Metz Paradise, all of which are chiefly propagated from cuttings.

I have tried the Doucin and French Paradise, but find them worthless for our climate. Our wild Crab is undoubtedly what we have to depend on to the extent (if I may venture a guess) of at least 90 per cent. of the whole of the Apples that are worked in this country, the Paradise being only used as a dwarfing stock for certain varieties of Apples to be grown in the form of bush trained trees. It is claimed for this stock that it brings the trees into an early fruit bearing state, but I am afraid there are many varieties made to feed on this stock, which practical knowledge of their constitutions cannot justify.

For instance, what possible benefit can the bulk of the Codlin class derive by being compelled to vegetate on a stock weaker than themselves? They are, generally speaking, weak in wood and prolific in fruit, and require the strongest body for their support. Then we have the weakest growers and the shyest bearers among the best dessert Apples, such, for example, as the Irish Peach, and Cox's Orange Pippin. What possible or permanent advantage can be expected for such by association with the dwarfing stock? It is true you may induce fertility on the one hand, but at the expense of greater weakness on the other, for as you sow you must reasonably expect to reap.

There are Apples which are materially benefited by co-operation with the Paradise stock, and they are the rampant growers. The chief recommendation for this stock is, however, for fancy gardening, where space is limited, and the Paradise will never become a successful competitor with the Free stock in supplying our markets from the great fruit plantations and orchards of this country.

I am a great advocate for what is known as the double working of the Crab stock; that is, to first work on it the strongest growers, such as Bramley's Seedling, on which afterwards bud the weaker sorts; and in converse manner for all strong growers and shy bearers to be budded the second time on such prolific sorts as Stirling Castle; and further, when you come to deal with weak growers and shy bearers only, work them on the body of the strongest and most prolific

bearers, such as Lord Grosvenor, as possessing great vitality with free and heavy cropping propensities.

In this double working you set up two distinct bodies, dependent on the Free stock for their existence, and the question may be asked, Will such co-operation interfere with the quality or flavour of the fruit? There has been much discussion in our gardening journals on the relation of scion to stock, but I maintain that it has never been satisfactorily proved that the stock of the Apple, Pear or Plum, exerts any influence whatever on either the quality or flavour of the fruit.

My contention is that as soon as the scion is in active life the stock is simply reduced to a passive agent in the distribution of strength, and the tree that grows thereon will only seek for such food as is essential to its natural requirements. I therefore maintain that the stock, deprived as it is of maturing its own wood and foliage, is rendered harmless to deteriorate, improve, or in any way influence the quality of the fruit.

In Pears we have only two stocks—the wild Pear and the Quince, known also as the Free and Dwarfing stock; and the practice of double working is probably more extensively carried out with Pears than with Apples; especially is this so in France, and I believe with a considerable amount of success.

Cherries also only possess two stocks—the wild and the Mahaleb, the wild or Free stock being chiefly used for standards, and the Mahaleb or Dwarfing stock for bush trees. The last named is closely allied to the Bird Cherry, and has the advantage of growing freely on very poor soil, also of starting into growth fifteen days later than the wild Cherry—a great point in its favour, on account of the trying weather often experienced when earlier trees are in bloom.

In Plums we have a long list of stocks, but those chiefly used in this country are the St. Julien, the common Plum, the Mussel, and the Myrobalan. The St. Julien is closely allied to the common Plum, and is a good stock on which to work the Myrobalan, to make stems to support Peaches, Apricots, and Nectarines established on them in the production of standards for training. The Mussel and common Plum are much less used now than formerly as stocks.

The Myrobalan seems to have come to the front, and probably 80 per cent. of Plums are worked on this stock—indeed, we use it entirely for both Plums, Apricots, Peaches and Nectarines, and find it answers better than any other, on account of its strong clean habit of growth and great freedom from gumming. It is a native of Europe and North America, and has been cultivated in this country for an unknown period.

This is the stock about which so much has been heard during recent years. It was announced as superseding our White Thorn for hedges. This I hold to be a delusion, and as a practical person cannot recommend it for that purpose.

I must not omit to mention the natural Peach and Apricot stocks, both of which are no doubt extensively used in the southern parts of Europe and America, but rarely worked in this country on account of their tendency to gum, and probably they are only at home when growing in the hottest and driest regions, and therefore useless for the British climate.

[An interesting and suggestive paper; but we know of some nurserymen who discriminate between stocks raised from the true Crab and those raised from mixed varieties of Apples, and known as "Free" stocks. These are raised from the pips of cider Apples chiefly, and are much more variable and more numerous than those raised from seeds of the Crab. The variation in stocks raised from the seeds of cultivated Apples is admitted by Mr. T. Lambert in his reference to those of the Codlin class. We know of highly profitable plantations of bush grown Apples on the "Free" stock, as well as on the English Paradise. We have also seen dwarf and productive bushes on the Crab when the seedlings have been specially treated, as, for instance, by Mr. Crump at Madresfield Court. We had in view the apparent circumstance of stocks not affecting the flavour of fruit that led us, on page 259 (March 30th), to ask for an explanation of the reason why Apples on the Northern Spy stock should be free from the American blight, while the same varieties on other stocks were devoured by the pest. Mr. A. H. Pearson referred to this matter on page 298 (April 13th), intimating that Apples on the Paradise are almost exempt from attacks, whilst those on the Crab will suffer severely. We should like to know what Mr. Lambert has to say on this subject. We did not know, and scarcely think that 90 per cent. of Apple trees raised in this country are worked on true Crab stocks.]

THYRSACANTHUS RUTILANS.—Few plants are more graceful and useful for indoor decoration during the winter and spring than *Thysacanthus rutilans*. Its long tubular flowers show to great advantage when the plant is used for the table. It is easily grown and lasts a long time in bloom, these attributes being sufficient to merit a place for it in every collection of plants. There is perhaps no other plant which possesses quite the same pleasing drooping habit when in bloom, and in these days, when small, graceful specimens are so much in request, the *Thysacanthus* would prove a boon to many who have to provide for table decoration.—H. P

A FLORIFEROUS CYPRIPEDIUM.

IN our issue dated January 26th of this year, page 61, we published a brief note under the above heading, which had been written by Mr. J. Dawson of Rangemore. Our correspondent now supplements those remarks with a photograph, from which the illustration (fig. 73) has been engraved. At the same time Mr. Dawson writes:—

"The *Cypripedium* referred to was raised in these gardens, and is the result of a cross between *C. bellatulum* and *C. venustum*, the latter being the seed parent. The plant is about five years old, and is now growing in a 5½-inch pot. The usual number of flowers borne on one stalk is two or three; all, as a rule, open simultaneously. It is a very vigorous grower."

The name of *Venubel* has been given to it, and no one will doubt that it is a vigorous grower when one knows that five flowers out of the six produced were expanded at one time, all of which can be seen in the illustration. The spike may be a fasciated one, but even then the number from one spike is exceptional, and it will be interesting to watch the plant's procedure in the future, and we hope Mr. Dawson will let us know, if he can, how the plant flowers next season.

CYPRIPEDIUM INSIGNE HAREFIELD HALL VARIETY.

THIS gigantic form, which was exhibited by the owner, E. Ashworth, Esq., at the Drill Hall at the last meeting in 1898, and of which a fine cut was given in the *Journal of Horticulture* on January 5th of the present year, is probably unequalled for size. But as showing how near some of these forms approach each other, I may mention that I recently saw flowering with Messrs. Hugh Low & Co. of Bush Hill Park, a form with flowers very nearly approaching it, and equally fine in build and colour. There is no doubt that many grand forms of this old species have long been in cultivation, but in out-of-the-way places where their merits have not become known.

ALBINO CATTLEYAS.

Nothing in pure white Orchids is so chaste and beautiful as are the white forms of the various Cattleyas, and few even of the rarest are more prized by their fortunate owners. Though in visiting exhibitions of Orchids, such as the Temple Show and the meetings of the R.H.S., these white forms are frequently seen, it is surprising what a number of plants may be handled before an albino turns up. Many of a washed-out looking, pinky white tint flower out of almost every importation, but these are far inferior to good coloured varieties, and do not merit the attention given them.

One of the most chaste, rarest, and unfortunately most difficult to grow, is flowering just now—viz, *C. intermedia alba*. The blossoms are absolutely white, and the habit is shorter than that of the type. Among the labiata kinds are many of these white forms, most of the best-known species having their albino. The white *C. Mossiae*, for instance, is a lovely plant, while *C. Trianae alba* is not less so. This latter is one of the best known of the white forms, having appeared as often as any. The old *C. labiata autumnalis* has produced its white form, and, like others, there are varieties with white sepals and petals, and various markings on the lip.

DENDROBIUM SUBCLAUSUM.

This will probably never become a very popular plant, as the genus contains too many good things for a newcomer of this class to make much headway. Yet it is not without beauty, and it is distinct enough from all other *Dendrobiums* to suit the most exacting in this respect. It is being tried as a pollen parent with some of the showier sections, and it is quite probable that some distinct hybrid forms may be raised by its aid; the colour, a bright orange red, being very unusual in the genus, and having been found very potent in other genera, as witness *Laelia harpophylla*, and *L. cinnabarina*.

DENDROBIUM BRYMERIANUM.

In the rush for novelties among *Dendrobiums* this beautiful species seems likely to be forgotten, as those who have it do not seem to think it worth showing. As a matter of fact few are more worthy of care, the finely fringed lip and its bright golden yellow colour being quite distinct from every other. The plant is an evergreen, but of different habit to most other evergreen species, the nearest to it being *D. fimbriatum*. The roots are very strong and vigorous, and young plants are freely produced on the tops of the older stems, thus forming a ready means of propagation. Taken off and placed about half a dozen

in a pot or basket, they make nice plants much quicker than old divided up specimens. The plant should be purchased in flower when possible to secure a good form.

PHALÆNOPSIS LOWI.

I recently noted a number of plants of this pretty species, and so finely were they pushing up that I asked for particulars as to their culture. As I anticipated, they were only in their third year, and therefore had been growing in this country just long enough to get thoroughly established while yet retaining much of their innate vigour. Beyond this the culture was similar to that advised in the *Journal of Horticulture* on several occasions. Personally I have always found that plants which seem to take naturally under cultivation to the deciduous habit noticed in their native country are the longest lived and most satisfactory.

But it will not do to force this rest upon plants that do not take it naturally. If sufficiently dried to lose their foliage the probability is that the last has been seen of it, or at all events the ensuing season's growth will be such that the experiment will not be tried again. As to compost, the less the better. A little clean sphagnum moss about rough blocks of apple or teak wood is ample for the strongest plant.

FIG. 73.—CYPRIPEDIUM VENUBEL. (Six flowers on one spike.)

By all means sink these blocks into pots of moss and charcoal if convenient, as a few adventurous roots may find their way to it, and if so they will strengthen the plants materially. If they do not, the moss being about the blocks will keep the latter moister, and this of itself is an advantage.—H. R. R.

SPRAYING FRUIT TREES.

REFERRING to Mr. Jno. Miles' article on page 272, April 6th, in *Nova Scotia* $\frac{1}{2}$ to 1 lb. rock or crude caustic potash is commonly used, both for spraying Apple trees before leafing and painting tree trunks for scale, &c., any time during the year. I have myself used potash up to 1 lb. per gallon on tree trunks, but I think this is unnecessarily strong.

In one of the best young orchards I saw in Nova Scotia the stems of the Apple trees had been yearly washed with $\frac{1}{2}$ lb. potash to 1 gallon of water. I do not think this is too strong for last year's growth, though for economy a weaker solution might be used.

This spring on the farm I have sprayed Apple and Plum trees of all ages with $\frac{1}{2}$ lb. potash to 1 gallon of water. I bought 1 cwt. of crushed caustic potash, highest strength 96 to 98 per cent. of potash, at 5½d. per lb. I would, however, have preferred American rock potash as being less expensive, but the package was too large for my requirements, and I do not think so pure a potash is necessary as the one I used.

Wide-brimmed straw or rush hats are used in Canada for spraying, costing about 5d. I did not see or hear of any other protection for the face employed. In case of a dose in the face I should advise lathing it at once in water and applying olive oil or grease without salt. The veil seems a good idea. I know the strong solution is rough on the hands unless protected by indiarubber or thick leather gloves.—C. H. HOOPER.

EXPERIMENTAL HORTICULTURE.—2.

(Continued from page 271.)

IN Germany experimental work is carried on extensively, but chiefly in connection with agriculture. There are fifty-four such stations, besides numbers of chemical laboratories, where analyses of soils and products can be obtained by farmers or others; but Dr. Voeleker informs me that in few cases does horticulture receive much attention, though there is one important establishment at Geissenheim, near Bingen on the Rhine, which, besides being a kind of national school of horticulture, is also devoted largely to fruit culture in demonstrative or experimental work.

In other European countries something is done in experimental work, especially in Switzerland and France. The total number of stations on the continent, Professor Warrington tells us, is 190, besides 120 laboratories.

At Versailles, near Paris, is a national school of horticulture, though little elaborate experimental work is done there, and the same remark applies to the 30,000 school gardens in France, useful as they undoubtedly are for demonstration and instruction.

In some of our colonies a few stations are established, especially in Australia and New Zealand, but there is little of a systematic or general character.

BRITISH EXPERIMENT STATIONS.

Coming to Great Britain, in which both agriculture and horticulture is of so much importance, we find that the State has done nothing in aid of experimental work. Whatever has been undertaken has been at private expense, by local bodies, or by societies, and it has thus wanted the uniformity of organisation so necessary in work of this kind. There is an institution, however, which, though devoted solely to agriculture, deserves a few words in these remarks, because it is a model of experimental organisation and patient, continuous research that stands unrivalled. I refer to Rothamsted, in Hertfordshire, where Sir John Lawes and Sir Henry Gilbert have conducted a most elaborate series of manuring and cropping experiments, the records of many of which now extend over fifty years. The work was commenced in 1834, and more systematically in 1843, so that the results of a long period under the same system and management are now available for comparison. The system of recording results is also very thorough, and some idea may be formed of the work when it is stated that 45,000 bottles of experimentally grown vegetable produce, animal products, and soils or ashes, are now stored in the laboratory. Sir John Lawes has not only maintained this great institution at his own expense, but has further most munificently devoted a sum of £100,000 to continuing the work after his death, the matter being vested in trustees and a committee of management.

Another institution, framed on a similar basis, is the Experimental Farm at Woburn, established by a former Duke of Bedford, and carried on by the Royal Agricultural Society under the direction of Dr. A. Voeleker. There some twenty years of valuable work has been performed, and the chief records have been recently made available in a condensed form.

COUNTY COUNCILS.

Some of the County Councils have commenced experimental work on a small scale, but it seems that they might well devote more of their energies and finances to such purposes, with great prospective advantages to their districts. In Wiltshire, for several years experiments have been well conducted in the Warminster district in connection with Potatoes, manures, spraying, size of sets, and wide planting being dealt with very carefully and thoroughly. The results have also been published in a convenient form. In Essex, experiments have been commenced in relation to manurial trials and other matters concerning agricultural crops, and, the *Journal of the Technical Laboratories at Chelmsford*, edited by Mr. D. Houston, F.L.S., gives the results of these in a series of reports and special articles.

At Droitwich, in Worcestershire, an experimental and trial garden has been established under Mr. James Udale, the chief Instructor in Horticulture for that county, and the report issued at the end of the year showed how comprehensive and useful such horticultural stations can be rendered in good hands.

In Derbyshire experimental fruit stations are established in certain districts. All the more useful varieties and forms of trees are grown in the best manner in which the soil and situations permit, and demonstration lectures given to visitors who attend, by Mr. Edward Luckhurst.

Amongst all the County Councils Surrey stands pre-eminent in the attention devoted to horticulture, and has developed a system which is admirable in every respect from an instructional point of view. This has taken the form of establishing continuation school gardens where, under the direction of qualified local teachers, the boys are encouraged to learn the best methods of treating the principal

garden crops. As both manures and seeds are supplied, it is obvious that such gardens can be rendered partly experimental as well, and I believe this is done to some extent under general supervision. There are no less than 370 plots in thirty different districts, and during the past year 5000 distinct crops have been raised, affording great scope for observations. In connection with this work the chief instructor says:—

“Every year experience proclaims more clearly that there is more virtue in deep culture and soil division, with frequent hoeings for weed prevention, and the incorporation of good natural or farmyard manures for imparting humus and holding moisture, than is found in the application of chemical manures alone, and apart from good manipulative work. Given this work, and natural manure, a supplement of wisely chosen artificials may be profitably applied to some soils and crops, but unless they are used with knowledge—which cannot well be had without actual experience—nothing is more easy than to waste money by investing largely in them.”

In addition to the school gardens trials of selected varieties of Peas, Potatoes, Kidney Beans, Carrots, Onions, and Beet are conducted in large groups of allotments, in order that the allottees may see for themselves what are adapted for the particular site and soil, and the resulting produce is used in the school gardens. This method is considered more directly useful to large numbers of workers, and also more economical than having an extensive trial in one district alone, where the soil cannot be the same as that which of necessity differs so much in the various allotment stations.

One trial of Potatoes was, however, of wide scope, as the same seventy varieties were grown in soils widely differing in character. As a result 220 dishes were arranged in the Public Hall, Carshalton, and from these thirty varieties were chosen as being suitable in size and shape for use. These were cooked by a County Council expert, with the results published, but a brief digest can only be given here. “For *quality* Goldfinder, Supreme, and Satisfaction were the best from dark boggy soil: Windsor Castle, Satisfaction, and Renown from clay soil; Supreme, Satisfaction, and the Bruce from dark sandy soil; Colossal, Satisfaction, and Windsor Castle from chalky soil; Challenger, Chancellor, and Duke of York (early) from sandy peat soil; Future Fame, Satisfaction, and Best of All from gravelly soil; Triumph, Satisfaction, and Windsor Castle from marly soil; Victory, Early Regent, and Dean's Renown from loose sand; Triumph, Victory, and Satisfaction from strong loam; Puritan (early), Windsor Castle, and Dean's Renown from dark porous soil.” Such practical work as that indicated in these notes must appeal strongly to all who are concerned in the advance of gardening.

Continuation school gardens are numerous in Kent, and more is done for allotment holders than in any other county by the giving of prizes for the best plots. The work is carefully estimated, and a penny a point given to those men who obtain above a certain specified number that is considered to represent creditable work. This is probably the simplest and best method of allocating such prizes that has yet been devised.

In Northumberland I understand an experimental farm has been established under the direction of Dr. Somerville, and in a few other counties some efforts are being made in a similar direction. For instance, in the Isle of Wight a small experimental garden is being formed, under the management of the horticultural instructor, Mr. S. Heaton; and I am informed that youths and adults are taught the principles and practice of gardening in Shropshire. Some of the agricultural colleges and farmers' societies also carry out experiments of various kinds, but necessarily in an isolated, and in some cases in a fragmentary way.

CHISWICK.

Amongst strictly horticultural institutions, established and carried on by societies, honourable mention must be made of the Royal Horticultural Society's garden at Chiswick, where for a long period useful work has been performed in the trial of varieties, and in experiments with stocks and other ways. It must be a subject of regret, however, that the funds of this Society have never seemed to permit its garden to be developed on a wider basis. There has been no lack in the administrative skill, for the R.H.S. has been fortunate in procuring able secretaries and superintendents, while its councils and committees have included the foremost horticulturists of the day throughout the present century; therefore it is to financial difficulties of many years that we must look for the explanation of the fact that experimental work has not been more extended. There is no question that the R.H.S. has rendered more service to horticulture during the present century than any other organisation, and in recent years its usefulness and finances have been so much increased that we may hope for still further improvement. More light is needed on many difficult problems, and it will only be by the multiplication of experimental stations and the accumulation of accurate records that systematic and reliable data can be furnished.—R. LEWIS CASTLE.

RECENT WEATHER IN LONDON.—Though we have had some bright weather of late the nights have proved very cold, either from winds or frosts. On Sunday evening rain fell rather heavily for some time, but Monday and Tuesday it was dry, though the latter day was very dull at intervals. On Wednesday it was fine, with a pleasant breeze.

— WEATHER IN THE NORTH.—For the fortnight ending the 17th inst., the weather has been highly unfavourable to vegetation. Piercing northerly winds have been continuous, and sharp frosts of from 4° to 6° have occurred almost nightly. From some northern counties pretty heavy snowfalls are reported, and 12° frost from a county well to the south. The night of Sunday was keen, 6° frost were recorded, and all the north hills are for some time white near to their bases.—B. D., S. Perthshire.

— ROYAL GARDENERS' ORPHAN FUND.—We have much pleasure in announcing that Sir Reginald Hanson, Bart., M.P., has kindly consented to preside at the annual dinner of this Charity, which will take place at the Hotel Métropole, on Tuesday, July 18th.

— SOWING PARSNIPS AND OTHER ROOTS.—There is no accounting for the action of many growers who sow their root crops, especially Parsnips, weeks before there is any need. The ground may be in the worst of order, and the weather quite unfit, yet they think something very untoward has happened unless the Parsnip seeds are in with the early Broad Beans. Beet, again, is often sown far too early, the consequence being that the roots grow very large, and are wanting both in colour and flavour. By all means sow a drill or two of either for an early crop, but as soon as the main crop comes in, the remainder, if any, of the early ones may as well be thrown away, for there is no question about the difference in quality of the late sown roots. From seeds sown in April Parsnips prove a most useful vegetable, as does Beet when sown in May.—C. H.

— SOCIÉTÉ FRANÇAISE D'HORTICULTURE DE LONDRES.—The bulletin of this estimable Society has just reached us, and we find its gross of pages full of matter that is always interesting, and, in many cases, instructive. Details are given of the several meetings that were held in the past year, with a special report of the annual dinner which took place in January under the presidency of Mr. K. Drost. This function seems to have been one of the most successful within the existence of the Association, due not alone to Mr. Drost, but also to Mr. Geo. Schneider and his energetic co-workers. From a practical point of view the value of the publication lies mainly in the several articles on various plants and flowers. Young Frenchmen resident in England who are not in communication with the Society should write to the Secretary, Mons. Roger Bréauté, 20, Bedford Street, Strand, London.

— ROYAL BOTANIC SOCIETY.—The following medals and certificates were awarded for miscellaneous exhibits and meritorious plants at the exhibition of this Society, that was held on Wednesday, the 12th inst.:—Large bronze medal to Messrs. A. W. Young & Co., Stevenage, for Chivias and Pelargoniums; large silver medal to Messrs. J. Laing & Sons, Forest Hill, for flowering and foliage plants; large silver medal to Messrs. B. S. Williams & Son, Upper Holloway, for Orchids and foliage plants; large silver medal to Messrs. Hill & Sons, Edmonton, for Ferns; large silver medal to Messrs. J. Carter & Co., High Holborn, for Cinerarias; large silver medal to Messrs. W. Paul and Son, Waltham Cross, for Tulips and flowering plants; silver medal to the St. George's Nursery Co., Hanwell, for Cyclamens; small silver medal to Messrs. Barr & Sons, Covent Garden, for Narcissi; silver medal to Mr. W. Rumsey for Roses; silver medal to Messrs. Hogg and Robertson, Dublin, for Narcissi and Tulips; large bronze medal to T. S. Ware, Ltd., Tottenham, for Narcissi and flowering bulbs; bronze medal to Messrs. Morle & Co., Finchley Road, for Mignonette and Acers; and large bronze medals to Mrs. Vince, Leighton; Mr. Prewett, Rayleigh, for table decorations. Floral certificates were accorded to Messrs. W. Paul & Son for Camellia Dr. Balthazar de Mello and single Tulip Queen of the Netherlands; and to Messrs. Barr & Son for Narcissus Duke of Bedford. A botanical certificate was granted to Messrs. B. S. Williams & Son for Cymbidium Devonianum and Phaius Normani.

— SPRING VISITORS.—Swallows were first seen here on Saturday the 15th, and the cuckoo was heard on the 16th. Last year the dates of these were the 4th and 17th of April respectively. The nightingale, which was heard on the 14th last year, has not up till this date yet made its appearance. We cut our first 100 Asparagus out of doors on the 12th. Last year it was cut on the 11th, so there is not much difference in the season.—C. ORCHARD, Bembridge, I. W.

— BRUNFELSIA EXIMIA.—Grown as a pot plant, this usually presents a more or less stunted appearance, due to its habit of producing a large quantity of flowers at the expense of growth. When planted out, however, more growth is made with better foliage, and the flowers are borne quite as abundantly as in the former case. The flowers are produced from the tips of the shoots during spring and early summer. They are rather more than 1½ inch across, deep purple when they first open, becoming paler as they age, and sweetly scented. For planting out in an intermediate house it is excellent, flowering very freely, and being showy. A mixture of peat and loam, with plenty of sand added, and a well drained border, is all that is necessary to insure success. It is a native of Brazil, and a figure of it may be seen in the "Botanical Magazine" (t. 4790).—D. K.

— TORQUAY GARDENERS' ASSOCIATION.—Though only seven years old this Society is a very flourishing one, and has done much useful work in disseminating horticultural knowledge in the district. The essays that are read at the meetings are invariably of a useful character, as readers of the *Journal of Horticulture* will be aware, as we have from time to time published more or less lengthy extracts from them. At the recent annual meeting when the Committee's report was presented the stability of the Association was commented upon, and from the balance-sheet we are pleased to see that the amount in hand is greater than it was last year. The Hon. Secretary, Mr. F. C. Smale, Isaline, Avenue Road, Torquay, is indefatigable in his endeavours to maintain the status of the Society.

— "FAMILIAR WILD FLOWERS."—Many readers of the *Journal of Horticulture* will have taken this work in its earlier editions. There will, however, be numbers of young gardeners to whom it is unknown, and now that Messrs. Cassell & Co. are republishing it the opportunity should be grasped of adding it to the library. It will be completed in twenty-five parts, for each of which the price will be sixpence, and of these three, containing thirty coloured plates, are now before us. The author, Mr. F. E. Hulme, F.L.S., F.S.A., has dealt with his subjects concisely, yet withal instructively, and the work cannot fail to be of value to the diligent reader. The sections ready contain admirable representations of the Field Convolvulus, Field Rose, Meadow Cranesbill, Silverweed, Apple, Borage, scarlet Poppy, Arum or Cuckoo Pint, Sweet Violet, Primrose, Hyacinth, Dandelion, Bulbous Crowfoot, common Orchis and Broad-leaved Garlic, yellow Iris, red and white Dead Nettle, Goldilocks and Water Ranunculus, Periwinkle, Lesser Celandine, Harebell, Bush Vetch and Sweet-scented Vernal Grass, Storksbill, Bramble, Honeysuckle, Valerian, Small Knopweed, Cowslip, Toadflax, pink Persicaria, Tormentil and Cinquefoil. "Familiar Wild Flowers" may be obtained through any newsagent or bookseller.

— PINCHING FRUIT TREES—A QUESTION TO ANSWER.—The question is this, Can any practical readers of the *Journal of Horticulture* prove that the pinching or stopping of the shoots of fruit trees will produce large healthy fruit buds on trees so pinched earlier than trees that are not pinched? I have been a grower of hardy fruits for more than twenty-two years. I have done the pruning myself, and taken deep interest in the growth of the trees, but I have never been able to prove that pinching produced fruit buds on the current year's growth capable of producing large healthy flowers. The best test would be to plant one dozen Apple or Pear trees, in six varieties, all worked on the same kind of stock, all the trees to be carefully planted with their roots near the surface on a plot of well-prepared ground. After the trees have become established and growing freely, let one of each variety be pinched in the orthodox way, to form fruit buds, allowing the other six to grow unpinched, but removing useless crowded growths, to enable the foliage to obtain abundance of sun and air for the maturation of the leaves and wood; also taking out the points of the very strong shoots that are robbing the weaker. Pinch away at the first six trees as much as you like. My opinion is that the six trees merely pinched for training will produce more and better fruit in six years after planting than the six trees will that have been systematically pinched for manufacturing fruit buds. Many varieties will produce fruit buds on the current year's growth of both Pears and Apples when their roots are in a proper medium without pinching or stopping in any way.—GEO. PICKER.

A dull and almost sunless week, with cold winds and much rain.

— **THE NEW PENNY PAPER.**—We have been requested to say what we think of the "Gardener," that was advertised in our columns a few weeks ago. After looking through copies which we received from the publisher too late for reference last week, we have no hesitation in stating that, in our opinion, the new comer supplies good value for money, and is likely to make its way in the world. It has already, we have no doubt, found its way into the hands of persons who have not hitherto read a gardening paper, while two of our friends say they regard it as a good auxiliary to the *Journal of Horticulture*. There is so much to be said on gardening, that no paper can say it all, and we believe there are plenty of readers for all that can be said on various points, and in various ways, on the peaceful art, which is always growing, in our garden-loving country.

— **CAMBRIDGESHIRE HORTICULTURAL SOCIETY.**—For upwards of threescore years and ten has this Society been in existence, and yet the fact that it is this season holding three distinct exhibitions proves that it has not lost the vigour of youth. The first show is fixed for June 13th, when the classes number over six dozen. It is on this date that special prizes, open to all comers, are accorded for Roses, 10 guineas being offered in three prizes for thirty-six distinct varieties. On September 7th there are classes for plants, flowers, fruits, and vegetables, Dahlias occupying a conspicuous position. The third and last show comes on November 8th and 9th, when the Chrysanthemum will reign supreme. In an open class for thirty-six Japanese, distinct, £12 is offered, and for twenty-four incurved, in not less than eighteen varieties, £6 is allotted, there being three prizes in each instance. Mr. Arthur Matthew, 20, Trinity Street, Cambridge, is the Hon. Secretary, and from him schedules, entry forms, and other necessary information can be obtained.

— **WEATHER AND CROP PROSPECTS IN GUERNSEY.**—An uneventful winter, broken only by the awful disaster to the s.s. "Stella," the day before Good Friday, which has cast a cloud of sorrow over the Channel Islands, has kept me silent longer than usual. The weather, on the whole, excepting for about a fortnight early in March, has been very mild. On Friday and Saturday, 7th and 8th of this month, there came a severe gale of wind, which did great damage to the Daffodils and other flowers. Now the weather is of a typical April character—showers and sunshine. Our winter crops of Broccoli and Radishes have been anything but satisfactory, Broccoli heads being generally very small, but that of good quality has realised fair prices. Greenhouse Potatoes are running very small in size, and crops are, on the average, light, the almost entire absence of sun during the months of December, January, and the early part of February being much against their growth. The same cause has operated, to a great extent, on the crops of French Beans and Peas, the later sowings having done much the best. The early Daffodils have been fine, and have, considering the quantity both here and in the Scillies, sold at very fair prices. The Ornatus, just coming out in their full beauty, have suffered most from the effects of the gale. The prospects of the Tomato crop in the heated houses are, so far, very good, plants generally looking the picture of health, and with fruit well set. A few parcels have already been sent to England, but picking will not be general for about another fortnight or three weeks. The genial rain we have had, lately has done great good to all outdoor crops, which have now got a good start. There is a very abundant show of Pear blossom. Plums and Cherries are little grown here.—X.

— **GARDENING APPOINTMENTS.**—Mr. Frederick Bulford has been appointed gardener to Sir G. J. Dashwood, Bart., Kirtlington, Oxford; Mr. Alfred Smith in a similar capacity to J. Jaffray, Esq., The Skilts, Studley, Warwickshire, both of whom have lately been foremen under Mr. A. D. Christie at Ragley Gardens, Alcester.

— **FOR CRICKETING GARDENERS.**—We read in a London daily that at Boreham, near Chelmsford, hard by the fertile stream of the Chelmer, a red Willow tree was planted in 1835. In a little over sixty years this tree, which has recently been felled, was found to weigh 11 tons; it was 101 feet long and 5½ feet in diameter. Messrs. Warsop and Son, of St. John's Wood, were the purchasers, and made 1179 cricket bats out of the "prime" cuts. One of our young "Graces" says it is a pity the tree did not grow cricket balls as well.

— **POISONOUS PLANTS.**—The Consulting Botanist of the Royal Agricultural Society has just presented a report to the Committee dealing with the danger to animals and stock which arises from poisonous plants growing on or near pasture land. The familiar Buttercup comes under the ban as "a worthless and dangerous weed," all its varieties being more or less acrid, and farmers are warned that it should not be allowed to exist in any pasture. The Cypress has apparently been badly libelled, for common opinion puts it down as rank poison for cattle, whereas the report declares that although it is astringent no record exists of its having caused any injury to stock. Yews, Laurels, and Rhododendrons are very poisonous, the two latter yielding an essential oil rich in prussic acid. Cattle having access to them die with all the characteristic symptoms of prussic acid poisoning—laboured breathing and suffocating convulsions—and should never be allowed near them.

— **BIRMINGHAM GARDENERS' ASSOCIATION.**—At a recent fortnightly meeting, Mr. Walter Jones in the chair, an interesting lecture, entitled "Hardy Spring Flowering Plants," was given by Mr. W. B. Child, Acock's Green. The interest was also enhanced by a small collection of plants in flower of such as Polyanthus, Primroses, Anemones, Heaths, and Doronicums brought by the essayist. Mr. C. R. Bick, gardener to Walter Chamberlain, Esq., brought several examples of berried branches of Aucubas. Mr. Child, in the course of his remarks, drew attention to Nature's disposal of Alpine and spring flowering plants as a study for the planter, advocating massing in preference to the "dotting" system for a larger proportion of the plants than is generally seen. He also recommended the imitation of natural rockery as far as feasible. Naturalising bulbs on the turf, amongst shrubberies, and other suitable sites, was referred to. An animated discussion ensued, and mention was made by one of the members of the two large groups of Grape Hyacinths (*Muscari botryoides* and *album*) noticed by him a few weeks ago on each side of the drawing-room entrance of the conservatory at Highbury, and which, in conjunction with a mass of white Lilacs in close proximity, produced a chaste and charming effect, an additional feature being the delightful fragrance of a long row of yellow and rose coloured double Wallflowers on the side stages, amongst Cinerarias, Primulas, Hepaticas, Hyacinths, and other bulbs.

— **COLLEGE OF AGRICULTURE, DOWNTON.**—The winter session of this College terminated recently, when the following awards were made:—The diploma or certificate of membership of the College after two years' residence, and passing in all the subjects taught, to L. E. Clarke, 9, Chichester Street, London; T. P. Goodchild, Pidnell House, Farringdon; D. A. Drummond, Blinkinsop Castle, Northumberland. Certificates of practical proficiency—D. H. Wood, Elim, Lyndhurst Gardens, Hampstead; G. W. Carpenter-Garnier, Rookbury Park, Wyckham; C. Mitchell, Longnor Hall, near Penkridge, Staffordshire. Prizes were also given in various subjects as follows:—L. E. Clarke, agriculture, knowledge of live stock, butter making, estate management, book-keeping and forestry; H. R. Board, Farley, Westerham, agriculture, valuation of farm stock, estate management, building construction, book-keeping, veterinary science, chemistry, and practical chemistry; H. W. Ethelston, Hinton, Whitechurch, Salop, agriculture, valuation of farm stock, building construction, and book-keeping; D. A. Drummond, valuation of farm stock and ploughing; G. W. Carpenter-Garnier, valuation of farm stock; T. S. Bliss, 36, Via de Delfini, Rome, farm machinery and practical chemistry; K. B. Foyster, All Saints' Rectory, Hastings, milking; G. W. Orr, Cowdon Hall, Neilston, N.B., milking and estate management; A. C. Shakerley, Leaton Knolls, Shrewsbury, waggon driving; T. P. Goodchild, building construction, veterinary science, and chemistry; O. F. C. Yarborough, Camp Mount, Doncaster, veterinary science; J. Benson, Harnage House, Shrewsbury, chemistry, practical chemistry, and physics.

— GERBERA JAMESONI.—In reading your Journal of the 13th inst. I saw the answer to "F. C." re the above plant, and as I happen to have several plants which I can spare I thought it might be worth while to write to you. I have sold several plants to Messrs. Hugh Low & Co. (who showed one before the Royal Horticultural Society recently), the Earl of Searbrough, Bishop of Salisbury, and others. The reason I have some plants is that a brother of mine in Africa saw the plant, and sent me some seeds. I intend advertising plants, both in bloom and out.—HEDLEY H. COOMBS.

— ECHEVERIA METALLICA.—This bold member of the Cotyledon tribe is known by many, but grown by few. It is an effective plant for the centre of carpet beds, or wherever a conspicuous object is required; but the difficulty I have experienced is to propagate it, though perhaps other readers and growers may have been more successful. For some years I grew about a dozen stock plants, which were annually planted out in the summer, lifted in the autumn, potted and stored in a cool house. Scarcely any water was given during the winter, but the plants kept in good condition. When they got leggy through losing their lower leaves the stems were cut off at planting time, and though the plants were put out with scarcely any root they never appeared to suffer, and when lifted they had again thrown out abundance of fibres. Numerous offsets were put in with the idea of propagation, but invariably they ran away to flower spikes and failed to make plants.—H.

— IS THE CROTON DECLINING?—Perhaps I shall get pulled up short by Croton lovers for suggesting such a thing, but, like Rose Dattle, I only ask. I often think it must be so, for there does not seem to be anything like the same interest taken in these gaily tinted foliage plants as was the case some years ago. Possibly the decline of the popularity of specimen plants has had something to do with it, and it may be that the tints of the Croton do not appeal to growers as they did of yore. I think the surest sign of the decline of any plant is the absence of new forms. I remember when there was a kind of run on new Crotons, but though I con the reports of the Royal Horticultural Society closely I have seen no account recently of a new Croton gaining an award, or even being put forward for one. Perhaps the cut flower demand has spoiled the Croton's chances in private establishments, for the plant requires stove temperature and a good deal of attention, while its chief use is for table decoration.—G.

— CAMELLIA RETICULATA.—For three or four weeks at the latter end of March and beginning of April the large specimen of this species, growing in the temperate house at Kew, makes a gorgeous display every year. At the present time it is at its best, and is worthy a visit from anyone interested in greenhouse plants. Although not so popular as *C. japonica* and its varieties, it has merits which warrant it more general cultivation, and as these become recognised it will doubtless be used freely for the decoration of large houses. In general appearance it has a looser and more graceful habit than *C. japonica*, with longer more acuminate leaves, and larger flowers. In the typical plant, which grows wild in the woods of Hong Kong, the flowers are single, those of the Kew plant being semi-double. When fully open they measure from 5 to 7 inches across, and closely resemble the flowers of a tree Peony. They are rich rose coloured, and are set off by a mass of bright yellow stamens in the centre, which mingle with the petals. It has been in cultivation for a long time, a figure being given in the "Botanical Magazine," t. 2787, as long ago as 1827.—D.

— PROFIT IN PALMS.—"I look upon these as a safer investment than freehold property," said one of our best known market growers to me recently when, after looking through some score or so of houses filled with them, I touched upon the financial side of the question. And there is no doubt he was quite right. A house of Palms is one of the easiest to keep in order if up to date methods of culture are practised, and each year all the popular decorative kinds increase in size and therefore in value. Another firm of growers in Middlesex has several houses filled with Kentias of the more popular kind; tens of thousands of plants in various sizes. One of the firm assured me that they were still understocked, and if the right class of "stuff" was on the market they would be buyers to a large extent. The demand for these is, in fact, unceasing and seemingly unlimitable; and with all the cry out about the unhealthy London fogs, it is a remarkable thing that a very large percentage of the decorative plants are grown within a few miles of the metropolis. Fog or no fog, there it is grown and from there it is distributed throughout the land. Our provincial nurserymen rely on London stuff, though possessing equal facilities for growth, and for Palms alone much money is annually spent by them that by growing the right class of material might be kept in their own pockets.—H. R.

— HYBRID MUSKS.—With the exception of Harrison's Musk, which has been so universally grown, and is known by all, the only real hybrid Musks I have known were three, quite distinct, raised by the late Mr. A. Clapham, who employed on the common Musk pollen from *Mimulus cupreus*, and, I think, *M. lutea*. Certainly his major hybrid was a fine yellow, large in bloom as Harrison's, but clear in hue. Then there was a very dwarf, compact, large-flowered yellow form, and one exactly similar in habit, but having flowers of a coppery red. This was certainly one of the *cupreus* cross. I grew and propagated these for several years at Bedford, but do not know whether they are still in commerce. Like Harrison's, they were sterile, no fertilisation with other pollen proving productive of seed. Had Mr. Clapham been alive he could have furnished much valuable information to the Chiswick Conference.—A.

— WHEN FLOWERS SLEEP.—Foliage for the most part sleeps by night only; but flowers take casual naps now and again when danger looms in the daytime. This is only what one might expect, for the flower is usually the part of the plant which does the most varied external business and holds the most specialised intercourse with the rest of nature. The leaf has relations with the sun and the air alone; but the flower has to attract and satisfy all sorts of fastidious and capricious insect assistants; it has to produce pollen, honey, and seeds; it has to provide for its own fertilisation and that of its neighbours; hence it may have to wake or sleep in accordance with the convenience of the outer world, just as a railway porter or a club servant must get up and go to bed, not when he chooses himself, but when his employers choose to make him. The rule with flowers is this: they open the shop when customers are most likely to drop in, they shut it when there is nobody about and when valuable goods like honey and pollen run a risk of getting damaged.—(Grant Allen in the "Strand.")

— VIOLAS.—It is great advantage in the employment of these dwarf growing plants in summer bedding arrangements that being hardy they can be planted out where to bloom in April, and thus get well established some time before the tender plants are put out. But for spring planting none are better than are those grown from cuttings put into a frame or shallow boxes, or under hand-lights in September, as they not only root freely during the winter, but because entirely from young tops make more liberal growth than do old or separated plants. Violas for summer bedding are preferably used as carpets on which various taller or decorative plants grow. Occasionally pinched to induce the formation of fresh flowering shoots, and especially with the seed pods regularly gathered, flowering goes on over a very long season. Probably no plants continue to bloom longer and need so little trouble. Then Violas associate admirably with other plants in mixed beds. But for this purpose the looser habited growers—and few are more charming than Duches of Sutherland or Archie Grant—do admirably, as they send up their long shoots to intermix with other plants so pleasingly, although any variety grown under such conditions will of necessity have greatly elongated shoots.—A. KINGSTON.

— FRUIT PROSPECTS.—The showery weather, with occasional gleams of sunshine, seems to be favourable to bloom expansion, for whilst it opens slowly, certainly it is doing so strongly, and at this moment of writing the earlier Plums are as white as snow. There will be no fear of harm from frost whilst the showers and the cloud remains, and showers do not seem to check fertilisation, indeed they rather aid it. Showers, too, will help leaf expansion, and tend to keep the young foliage from early attacks by aphids. Cold, dry, harsh winds encourage these pests materially. The late rains have thoroughly moistened the roots, and should prove helpful in inducing the fruit presently to swell rapidly. The other day I was asked, Does exceeding abundance of bloom on trees tend to check fertility, seeing that poor crops so often follow upon great bloom? Also, can anything be done to correct this trouble by thinning the bloom? I replied first to the latter, that something might be attempted to correct the trouble referred to in the previous question by pinching out on a bush or wall tree, or any other tree that could be thus controlled, one-half of the flower trusses, but not tearing away the woody spurs; that would materially relieve the tree of a great burthen, assuming that a heavy bloom was so great a burthen to a tree that it rendered fertilisation through poverty in pollen production difficult. It is a direction in which many persons may well experiment, and it would be a very practical experiment. We are too apt to regard a huge bloom on fruit trees with complacency, without stopping to inquire what its general effect may be on the tree. Gooseberries and Currants usually bloom regularly and evenly, hence they fruit regularly, but Apple, Pear, and Plum trees in particular commonly go to extremes. The variations oftentimes, diverse as they are, give us the same barren results.—A. D.

TRANSFORMATION IN FRUIT TREES.

WHAT an incentive it ought to be to the reader-workers of "our Journal" to record their experiences in its pages, after such a minutely detailed account on page 272 (April 6th) by Mr. Jno. Miles, of the method of combating the enemies there described of British fruit growers. That article is worthy of being framed and hung up in every fruit room in the kingdom. The writer of it plainly shows what may be achieved by exertion and perseverance (and there is little or nothing gained without). I do not believe that Mr. Miles is a grumbler about bad times for fruit growers, for I suspect he is too busy to grumble. I regard those men as benefactors to the British public who produce fruit of the finest quality and exceeding in value that of the foreigner. I wish there were more such workers as Mr. John Miles.—Geo. PICKER.

[Our practical and industrious correspondent should be grateful to the "foreigner" all the same, for, by the character of his wares, stimulating home growers to greater activity and the adoption of better methods in producing for the million fruit worthy of the name and nation. Mr. Miles' record of experience was very useful, and his notes were readily published.

The method advised by Mr. Molynoux in the lecture referred to on the page above cited was first made known to the British public through the *Journal of Horticulture* by an Englishman, Mr. Leonard Coates, who landed in America with about £5 in his pocket, and has for some time been one of the largest nurserymen and fruit growers in California.

We suspect there are many improvers of Apple and other fruit trees in Britain who are either "too busy" or disinclined to narrate their methods, while it is certain there are many spoilers of fruit trees. We could give instances of the peculiar methods of some of these so-called gardeners (whose ignorance is so great as to enable them to refrain from seeking knowledge anywhere), that would startle the Miles, Pickers, and other good men; but it is more pleasant to refer to the work of an improver.

A short time ago we had an opportunity of visiting the gardens of the historical Abbey of Battle, near Hastings. There is a fine kitchen garden there, splendidly managed, and numbers of trees that had when "taken to" by Mr. Cann got in the habit of growing everything that trees can support except Mistletoe and fine clean fruit. A crush and a crowd of useless wood and apologies for leaves, with scale and moss much more abounding than even small specked fruit, "not fit for sending in." Those were the characteristics. The trees, in fact, occupied much ground uselessly. The worst were rooted out and new trees planted, the remainder treated with—well, with "brains;" and here is nothing better when these are educated.

Saws and chisels were brought into operation, and all weak, worthless, and cankered parts cleared out, the better branches retained at 2 to 3 feet asunder, and the extension growths of these not shortened. The worst stems and branches were scraped, and all parts sprayed with the caustic solution mentioned by Mr. Miles. The ground was soaked during the resting season with strong liquid manure, and lime and soot were also used freely. The effect of the treatment was apparent in clean branches, fresh young growths, and bold leafage. By the thin disposal of these growths, so that the sun could shine between them, the foliage was of the best character, the wood well stored with nutrient matter, and as little or no shortening was done the stems became studded with bold fruit buds. The trees must very shortly be wreathed with blossoms of the finest character, to be followed, weather permitting, with tons of excellent fruit.

As affording evidence of what may be done in the renovation of crippled Apple trees, it may be stated that the produce of some of these old trees enabled Mr. Cann to "come in first" last autumn at the Crystal Palace in the class "open to growers in Surrey, Sussex, Hants, Dorset, Somerset, Devon and Cornwall." Such are the facts. What has been done in a few instances may be accomplished in many in improving fruit trees that are capable of renovation when the varieties justify the work. Though the practice cannot be carried out in extensive plantations, thorough soakings with strong liquid manure at any time, from the autumn to spring, when the liquid will pass down freely, have a far quicker and more potent effect in invigorating enfeebled trees than accrues from surface sprinklings of artificial manures, however good these may be; but thorough cleansing and common sense pruning in the form of branch thinning, with little shortening of the better parts, are essential accompaniments. Under such procedure, and in some cases of grafting, also especially by planting and intelligently managing young trees in wisely chosen varieties, such a transformation may be effected in home-grown fruit, which, if properly placed before the public, will compete successfully with any that can be brought against it in the best market in the world—Britain. It is a question of men and their methods, nothing else.]

ROSE SHOW FIXTURES IN 1899.

- JUNE 13th (Tuesday).—Cambridge.
 „ 14th (Wednesday).—York†.
 „ 21st (Wednesday).—Isle of Wight (Shanklin).
 „ 24th (Saturday).—Windsor.
 „ 27th (Tuesday).—Westminster (N.R.S.).
 „ 28th (Wednesday).—Bath, Croydon, Reading, Richmond, Maidstone, and Ryde.
 „ 29th (Thursday).—Canterbury, Eltham, Norwich, and Sutton.
 JULY 1st (Saturday).—Crystal Palace (N.R.S.).
 „ 4th (Tuesday).—Gloucester and Harrow.
 „ 5th (Wednesday).—Ealing and Hanley°.
 „ 6th (Thursday).—Colchester (N.R.S.).
 „ 7th (Friday).—Hereford.
 „ 11th (Tuesday).—Wolverhampton.†
 „ 13th (Thursday).—Brentwood and Helensburgh.
 „ 20th (Thursday).—Salterhebble.
 „ 25th (Tuesday).—Tibshelf.

° Shows lasting two days. † Shows lasting three days.

The above are all the dates definitely decided upon that have as yet reached me. I shall be glad to receive the fixtures of any Rose shows not named above, or those of any horticultural exhibitions where Roses are made a leading feature, for insertion in future lists.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

A CORRECTION.

WILL you allow me to correct an error into which I have unwittingly fallen in the present issue of "The Rosarian's Year Book," and wherein I stated that Messrs. Harkness had succeeded to the business of Mr. May in Bedale. I am assured that this is not the case. The present firm of Messrs. J. & A. May, of Hope Nurseries, continues the business, which was purchased by them from the late Mr. Henry May's executors about five years ago, and has not only been carried on by the May family for three generations, but is now in a flourishing condition.—THE EDITOR OF "THE ROSARIAN'S YEAR BOOK."

NOTES ON TOMATOES.

THE final potting or planting out of Tomatoes must be attended to now in all cases where the plants are sufficiently advanced in size. Some advocate planting them in a border, while others pin their faith on pot culture. The grower must be guided by circumstances. If the plants are not near the glass or in a very light position, it would be folly to plant them out permanently and expect them to fruit abundantly. In such cases they are better managed in pots, because the pots being portable, they can be easily elevated to positions near the glass, which is indispensable to the welfare and success of Tomato growing.

A low span-roof structure, well heated and ventilated, is undoubtedly the best house for growing Tomatoes. A border should run down each side with a base of wood or stone at no great distance from the glass. Four to 6 inches of soil may be placed in this about 14 inches wide, this being held together with a row of loose bricks, and if the base of the bed slightly inclines to the front ready escape will be afforded for the superfluous water. Good stiff holding loam, half decayed and turfy, is suitable compost. It will not need enriching with much manure, but burnt refuse and some pounded lime rubbish will materially improve it. Place out the plants not less than a foot apart on small mounds, just covering with soil to give the roots a start. More can be added as needed from time to time. The soil must be made firm about them, and not too freely watered at first.

In pot culture the final potting is made in 11, 12, or 13-inch pots. A small quantity of drainage should be effectively placed in the bottom of the pots. On this insert the plants, and add no more soil than will cover the ball when made firm. A very light position must be chosen. Sometimes a temporary shelf is requisite, as the plants must be near the glass. Water carefully until the roots have worked into the compost. As the plants grow and become established, the pots may be gradually lowered to the position they must ultimately occupy. As soon as practicable commence training a main stem to a wire under the roof. Rub out all others as well as side shoots originating from the axils of the leaves. The compost allowed them to root in will suffice until the first fruits are set, when fresh may be added. A little heat is beneficial to assist the early growth, but ventilation must be constantly allowed.—E. D. S.

EMBOTHRIMUM COCCINEUM.

ALTHOUGH hardy, and grown in the open in favoured localities in the S.W. counties of England, this South American Protead requires the protection of a cool greenhouse in most places. At present a plant is

Messrs. Veitch in 1853, and was figured in the "Botanical Magazine" (t. 4856) about that time from specimens supplied by that firm. It makes a somewhat loose bush, with leathery oblong leaves, 4 inches long by $1\frac{1}{2}$ inch wide, dark green above, glaucous beneath. The flowers are borne in dense terminal racemes. They are scarlet in colour, and $2\frac{1}{2}$ inches

FIG. 71.—EMBOTHRIMUM COCCINEUM.

flowering nicely in the Himalayan house at Kew, where its bright coloured blossoms are seen to advantage against the dark foliage of neighbouring Rhododendrons and Camellias. Though by no means common, it has been in cultivation in this country for close on half a century. It is recorded to have been in flower at the Exeter nursery of

long. The racemes on the Kew example are from 1 to 6 inches long. When once planted care should be taken not to disturb the roots, as it is a difficult plant to establish again if interfered with. Where it will grow and flower well it makes a gorgeous object during late spring.—W. D.

PROGRESS IN FRUIT PRODUCTION.

(Continued from page 302.)

REFERRING to our citation last week, Mr. Bear points out that his sentence, "Tabulated statements show that the totals for England and Wales have nearly doubled in the ten years that have elapsed since 1888," would appear to apply to orchards, "whereas the figures given are those of small fruits." The area of orchards, he points out, as given in the tables, only amounts to about 11 per cent. Mr. Bear gives the orchard and small fruit areas in separate tables. We are obliged by the correction, and continue the interesting and suggestive extracts, though they are only mere items characteristic of his copious production.

PLANTATIONS IN KENT.

"Messrs. William and Edwin Vinson together have about 1000 acres of Strawberries and Raspberries in the Orpington and St. Mary Cray districts; and when in partnership, until the end of 1897, they were the most extensive growers of these fruits in England. They had 650 acres of Strawberries and 350 acres of Raspberries, with a few acres of other kinds of fruit. Now Mr. William Vinson, to whom my visit was made, has about 300 acres of Strawberries, and his brother 350 acres. He is of opinion that the fruit industry is overdone. Fruit prices, he said, had fallen about 20 per cent. in the last twenty-five years, but are about the same as they were twenty years ago, or perhaps a little higher. At Crockenhill, near Swanley, Mr. John Wood, a very large and successful grower, has 600 acres of fruit, including 150 acres of Strawberries and 140 acres of Raspberries, the rest of the land being devoted to Apples, Pears, Plums, Damsons, Gooseberries, Currants, and a few Cherries. The Paxton is the principal variety of Strawberry, but Mr. Wood, like Mr. Vinson, complains of it as 'wearing out,' as shown by its mildewing badly. Royal Sovereign is being more and more extensively grown on this farm, though Mr. Wood considers it inferior to Paxton in flavour, and it does not travel so well—no other variety does. Mr. Wood will not have anything to do with the watery and flavourless Noble, early though it is, as he declares that it 'cripples the Strawberry trade,' meaning that it is a source of much dissatisfaction among wholesale and retail buyers. Messrs. Wood Brothers, successors to the late Mr. Thomas Wood, hold about 3000 acres of land in Kent, about 2000 acres being under fruit. The extent of their cultivation of Raspberries may be grasped from the statement that last year, a bad season, they expected to produce 500 tons of this fruit. Mr. Cannell stated that he had known 75 tons of Strawberries to be despatched from Swanley station in one day, in addition to large quantities sent by road. In the jam factory there are fifteen steam-jacketed vats in one row, and six others for candied peel. Mr. Leopold Wood, who manages the factory, stated that he expected to produce last season about 3500 tons of jam, 850 tons of candied peel, and 750 gross (108,000 bottles) of bottled fruit.

"In the Maidstone district Mr. Frederic Smith, of Loddington, was named by some good authorities as one of the best fruit growers in Kent, and a visit to his plantation of 200 acres fully confirmed this statement. He grows chiefly Apples, Plums, and Damsons as top fruit. Cob Nuts are the principal bottom fruit, half the land, or 100 acres, being occupied with them, and the trees under and among which they grow. Among the interesting notes in Mr. Smith's statements, the more important must be given in miscellaneous style. Cob Nuts pay fairly as a rule, and sometimes well. Three good crops had been grown before last year; but the crop of the recent season was expected to be only about half a ton per acre. In 1897 Mr. Smith produced 100 tons from 100 acres. He once grew the great crop of 2 tons per acre, while his brother produced the enormous crop of 3 tons. Many growers say that the Stirling Castle variety of Apple is of no good to them, as it is such a tremendous cropper that it wears itself out quickly; but at Loddington it is manured heavily, and the trees are gone over twice to cut off superfluous blossom twigs. When Plums are thick on the trees, thinning them pays well, as the green fruit realises money enough to pay for the labour. One peck per bush is a fair crop of Gooseberries, but half a bushel per bush is sometimes produced. Last season Gooseberries started at 8s. a bushel, went down to 2s. 6d., and rose afterwards to 5s. or 5s. 6d.

"Mr. W. W. Berry, Gushmere Court, Faversham, grows fruit and Hops on an extensive scale. At Selling, which is Mr. Berry's nearest station, I found myself in the midst of a great fruit and Hop country. The soil for the most part is a stiffish loam over brick earth, with a chalk subsoil 8 feet to 9 feet below the surface. Fruit does well with such a depth of soil before the chalk is reached, but not where the latter is near the surface. The price of land varies from £30 to £150 an acre when disposed of in considerable quantities; but small holdings with fruit upon them or suitable for fruit are much dearer. For example, half an acre of land with a tumble-down cottage upon it realised £140 shortly before my visit. As it lets at £10 per annum, it is not a bad investment at the price. Fruit plantations in full bearing let at £8 to £10 an acre, and the land of one that I saw, only five years planted, had

been bought at £55 an acre, and would now let at £6 per acre. A good Cherry orchard, Mr. Berry says, is worth £300 an acre if in full bearing. One farmer in the district has sixty acres of Cherries; another near Sittingbourne holds a still larger extent of young trees; and a landowner who has farms in hand has one hundred acres of this fruit. Fruit growing appears to pay in the district, and workmen who have saved money occasionally obtain a small holding, and do well at the industry; but Hops, when well managed, according to the occupier of Gushmere Court, pay better than fruit. Mr. Berry farms 600 acres of land, seventy acres being in fruit and 180 acres in Hops.

DURATION OF FRUITS.

"On the question of the duration of different fruits, Mr. Berry said that Raspberries would stand fourteen to fifteen years, Plums twenty to twenty-five, Cherries sixty to seventy on suitable soils, and Apples up to a hundred years. Gooseberries and Currants are commonly left twelve to fourteen years under fruit trees, but would last longer if required. Trees usually cover the ground almost completely in the period named, and the land is often laid down to grass. With respect to fruit on grass land, Mr. Berry's views correspond closely with those of Mr. F. Smith. Cherries always, and Apples generally, he said, do best on grass, and most Plums on arable land. Although the point was not put to him directly, it may be assumed that he would not recommend the planting of any fruit on grass, as all his directions indicate planting in arable fields. It is only after even Cherries and Apples are well established, and their roots have penetrated below the depth from which grass exhausts most of the fertility in the soil, that grass should be allowed to compete with them for nutriment.

"Berry's Early Kent is the Gooseberry which does best at Gushmere Court as the earliest for picking. In April last year it made 8s. a peck. It is a chance variety of unknown origin, and is of value chiefly to sell green, not being recommended as the sort to be ripened. Lancashire Lad and Whinham's Industry both flourish and bear well, but are comparatively late. The former is better than the latter to sell when ripe, while Crown Bob is better still to eat, if not to sell. Some very fine dessert Gooseberries of the Gunner variety are also grown. Of the Red Currants, Fay's Early is regarded as the best early variety, La Hative, Early Dutch, Late Dutch, and Scotch Red being also cultivated. Baldwin and Champion are the Black Currants; Paxton and Royal Sovereign the only Strawberries.

IN CAMBRIDGESHIRE.

"Under the valuable guidance of Mr. Arthur Bull, of Cottenham, many of the fruit plantations of that parish and of Histon, adjoining, were seen early in the season. A large portion of the land in Cottenham is on the lower greensand, the best of all formations for fruit. Bare land suitable for fruit is worth £60 to £120 an acre, and quite half the land in Cottenham is owned by the growers. About 1000 acres of land are under fruit in Cottenham, and about the same area is devoted to Asparagus, which, however, is giving place to fruit to some extent. Nearly all the fruit has been planted within thirty years, progress having been equable all the time. There are many small holdings, some only 2 or 3 acres, and others 7 or 8 acres, while few men hold more than 20 acres, and not more than two over 50 acres. Some of the men who have purchased 2 or 3 acres for fruit growing farm large holdings as tenants, growing ordinary farm crops. In reply to a question as to the smallest area of fruit land on which a family could be supported, Mr. Bull said he thought that owners of 6 acres saved some money. Mr. Bull said prices for fruit have varied greatly, but have not fallen during the last twenty years. He has 40 acres of fruit land, partly his own. He planted the first 8 acres twenty-two years ago, and the plantations are healthy and well cultivated.

"One of my most instructive visits was to the admirably managed fruit plantations of Mr. I. F. Thoday, of Willingham, Cambs. There are about 200 acres of fruit in that parish, besides what small growers cultivate, which cannot be easily estimated. Mr. Thoday has 45 acres under fruit, and is the largest grower in the parish. He grows Sutton's Earliest of All Tomatoes, outdoors, and in one year he produced 50 tons. Mr. Thoday strongly objects to crowded orchards, he appears to doubt whether thick planting in the first instance, and the removal of every other tree when necessary, is not more profitable than thin planting. He showed me a neighbour's orchard of Plums and Gooseberries, in which the trees are only 10 feet by 8 feet, and in some places 10 feet by 6 feet, as one of the most profitable in the parish. It is but 8 acres in extent, and he thinks it yields a profit of £400 in a good year. But every other tree now needs to be cut out, or the orchard will certainly deteriorate. Mr. Thoday himself made £800 on one occasion of 10 acres of Plums. Another highly remunerative crop was 50 tons of Gooseberries from 7 acres, with top fruit besides. Yet another was 2 tons of Raspberries from an acre and a quarter of land, sold at £25 a ton.

"In the Wisbech district, according to an authority in the neighbourhood, there are fully 6000 acres of land under fruit, most of it

being in Norfolk, but some in Cambridgeshire. Eighty tons of Gooseberries have been despatched from Wisbech Station in one day. Strawberries and Raspberries are very extensively grown, and Mr. Richard Bath and his partners, whose great fruit and flower farms were visited, gathered 40 tons of Strawberries in one day in 1896. The two firms of which Mr. Bath is head hold 900 acres of land, about 850 acres, as the foreman of one of the firms estimated, being under fruit, including 210 acres of Strawberries. The fine alluvial soil (some of it let at £3 an acre) is perfect for Raspberries, and apparently suits other fruits also. Very little fruit, according to my informant, was grown in the district sixteen years ago, when Mr. Bath started his great enterprise."

VALUES OF MIDDLESEX ORCHARDS.

MR. W. E. BEAR, in his article to which last week you made reference, seemed to regard £10 per acre rental per year for fruit orchards in Middlesex as very high. No doubt it is, but in the neighbourhood where I so long resided such rents were common for established orchards, although they fell somewhat later. When an orchard is planted, as so many in Middlesex are, with Apples, Pears, and Plums, fairly close, and Gooseberries and Currants almost densely between them, and is in its tenth or twelfth year, it is in the most fruitful condition, and the produce is on the average enormous. But such a method of cropping soon exhausts the soil, because when the top trees become strong they need all the root area the ground affords, whilst the roots of the bushes nearer the surface practically absorb all the surface manure dressing, and the trees get little.

If the top trees are at their best from the tenth to the fifteenth year, the bushes are best from the fourth to the tenth year, and certainly by the twelfth year they should be destroyed, thus enabling the tree roots to obtain needful food, whilst the surface might be cropped with Daffodils, Violets, Wallflowers, Queen Stocks, and similar plants, which being from time to time cleared off enables the soil to be freely dressed, and surface cultivated. Mr. Walker at Ham does not grow bushes beneath the trees, as they are generally of bush form rather than standards, but flowers are cultivated. By bush cultivation higher class fruits are obtained than is the case with standard trees, as these usually are of commoner varieties; not but that very free-fruited common varieties as a rule pay well, but then they do not produce that description of high-class fruits which are so much needed in our best markets.—A. D.

NOTES ON PEACHES.

PEACH BUDS DROPPING.

I SHOULD like to give my opinion on this point. Mr. Markham (page 252, March 30th) is of the opinion that the mischief is done before starting time. My aim has always been to prevent bud-dropping, and a few details as to my practice may not be out of place. Immediately the crop of fruit is gathered the border is dressed with lime, until it looks as if there had been a fall of snow, forking it into the border at once, and follow in a day or two with a thorough watering. The next operation is to work into the surface soil a mixture of charred ashes and soil, and the border is never allowed to become dry, as I think this is conducive to weakness in some portion of the tree. Instead of this we want continued progress to assist the growth and formation of the buds, and to encourage the storage of sap for the coming season. Constant watch is kept on the wood and buds, the house being ventilated to its utmost capacity, syringing being practised morning and night. When the wood is thoroughly ripe syringing ceases, and the trees are given their required rest in the lowest possible temperature.

At starting time, after seeing that the border is properly moist, we commence forcing with the ventilators a little open, and the pipes kept warm. This I consider the critical period in the dropping of the buds, which I attribute to the expansion and contraction of the sap, directly in connection with the expansion and contraction of the atmosphere. Bearing this in mind, I endeavour to make the atmospheric conditions as natural as possible. Early on each morning, and again the last thing at night, the houses receive a thorough syringing, the pipes being kept warm, and the ventilators a little open; water is given in accordance with the drainage of the border. I must have continually a free circulation of air passing through the Peach house, night and day, so that I may avoid any suspicion of weakness, and insure, so far as in my power, the perfect development of the flowers. Everything is kept scrupulously clean, which with the healthy growth induces each portion of the tree to perform its proper functions.

Artificiality is the cause of Peach buds falling. If the foundation is not laid by naturally well ripened wood, and the roots are unhealthy so as to do their duty when called upon, then failure must ensue. Imitate Nature so far as is possible, providing showers by the aid of the syringe; secure warm air currents through the house by proper manipulation of the ventilators, and provide a warm and genial instead of a cold sap-chilling atmosphere; and success should follow. In conclusion I may say that I am convinced sufficient attention is not paid to ventilation, as with fresh air and slightly more warmth in the pipes, we should do much better than is the case at present.—H. MITCHELL, *Druidstone*.

HARDY FLOWERS IN APRIL.

A BACKWARD season does not inspire one's pen, and such it has been up till now. The Daffodils are here, but not in the numbers we are wont to have at this time in ordinary seasons, and the laggards move slowly towards their opening stage. There are plenty of buds, and one cannot complain of sparse flowering, either among those in bloom or those which will follow on. Big clumps of *telamonioides* plenus, Henry Irving, Mrs. H. J. Elwes, and Tottenham Yellow give a welcome brightness below the grey skies above. Muscaris grow, the pretty clustered bells on their close spikes looking fine among the green leaves. I often think none is prettier than the old *M. botryoides*, but there are beauties, too, in the flowers of *M. conicum*, *M. botryoides* album, *M. Szovitzianum*, *M. racemosum*, and others. Puschkinias are yet in flower, and look pretty with their pearly white and blue blooms. A few late plants of *Scilla bifolia carnea* are still fresh, and *Scilla sibirica* has not yet passed away.

Seldom have we so few blooms of *Anemone coronaria* at this time as this year. There are many flowers on *A. blanda*, which has been later than usual. *A. apennina* has caught up with its congener, and with its white and rosy varieties looks pleasing. Charming, too, are *A. nemorosa purpurea* and *A. ranunculoides pallida*. Primroses and Polyanthes looked unpromising for a time, but they have been fast making up leeway and now are covered with bloom. The variety of colours and shades they give is very pleasing to see.

Arabis and Arabis have not assumed their full garment of flower, but are attractive for all that, with the purple and white blooms on their sheets of green. Some of the Dog's Tooth Violets are pleasing still, though others, as their wont is, have passed quickly away. Here is *E. grandiflorum*, and there is *E. Smithi*, with its light-looking butterfly flowers of white, with yellow base and purple-flushed exterior. In a rather moist but sunny place it is now established below a clump of *Primula Sieboldi*, which is as yet only an inch high. Some Alpine Primulas are in bloom, but the past winter has not favoured them, so that they give less bloom than usual. Neither *P. denticulata* nor its variety or sub-species *cashmeriana* are nearly so fine as they usually are.

The quaint Fritillarias are coming on. Already some of the varieties of *F. Meleagris* are in bloom. The peculiar, yet pretty, *F. acmopetala*, and the charming *F. pallidiflora*, with others, will shortly flower. On the rockwork the old-fashioned *Pulmonaria officinalis*, in several varieties, looks not uncomely in its own way, while the one named *saccharata picta* will be useful by-and-by with its white splashed leaves.

Rhododendron præcox has parted with its bloom for the year, but *R. ciliatum album* has taken up the tale, and now looks beautiful in its sheltered place. *Cytisus præcox* is showing colour along its stems, and *C. ratisbonensis* or *biflorus* will run it hard for first place among the hardy Brooms. On a sunny wall and against a trellis *Forsythia suspensa* is covered with golden blossoms. They look so fragile that one is surprised to see them last so long. *Erica carnea* is as fresh as ever, too, and *E. mediterranea alba* has also come into bloom. The *Doronicums* are not yet in full flower, but *D. caucasicum* is charming even now.

Sanguinaria canadensis—the Puccoon or Bloodroot—is as delightful as usual when it opens out to the sun; and *Triteleia uniflora*, which is a weed with some, is beautiful near by. A little *Ornithogalum*, whose acquaintance I have not long made, is *O. tenuifolium*, an attractive species which is, I am told, less obtrusive and encroaching in its ways than most of its friends. It is crowded with its silvery white flowers. Violets are delicious with their fragrance—a gift so precious as to make them prized for that alone had they not the additional beauty of colour to recommend them. In a shady place *Cardamine rotundifolia* has shot up its stems with their small white flowers, and the Saxifrages known as Magaseas, such as *S. cordifolia*, *ligulata*, or *Stracheyi*, have begun to bloom.

Not many of the Tulips are ready to flower, but the, as yet, rare *T. Kaufmanniana* has kept open for a fortnight despite the weather we have had, and a flower on a clump, sent me some years ago from Chios, keeps it company. There are double Daisies, Corydalises, the rare *Scilla italica alba*, with stray blooms on other plants, so that, late as is the season, its record of bloom is not a barren one. The impulse of Nature has come to the flowers, and bloom they must, cold and cheerless though the time.—S. ARNOTT.

A NEGLECTED CAMELLIA.—Perhaps Camellias are generally neglected nowadays, though it is gratifying to now and then meet with champions of this fine old flower. Only recently I saw growing on the back wall of a Peach house a tree of the old-fashioned single white Camellia now so rarely met with. The tree was a mass of bloom, and the pure white flowers with golden-yellow stamens were exceedingly effective. The outcry against the Camellia for some time past has been that the flowers are stiff and artificial-looking, but surely this cannot be said about the single white. Its delicate nature and tendency to drop makes it unsuitable for cutting, but when grown in pots and covered with flower there is no plant more effective at a time when bloom is scarce.—H.

GRAPE GROWING OUTDOORS AND IN COOL HOUSES.

THE Romans are supposed to have introduced the Grape Vine into Britain about A.D. 10, and Tacitus, some eighty years later, declared that "the moist climate was unfavourable to the Vine maturing its fruit." This indicates that the climate was not materially different 1800 years ago from what it is at the present time, and appears to have had little deterrent effect on the cultivation of the Vine in England, for the battle of Hastings was fought near a great plantation of Vines. Even war and the chase, the greatest foes of agriculture and horticulture, did not uproot the culture of Vines in England, and Domesday Book contains thirty-eight entries of valuable vineyards, two of 6 acres each in the Lea Valley, one at Ware, and one in Essex. In the Great Ouse Valley, the Isle of Ely was called the "Isle of Vines" in Norman times, and the vineyard of Peterborough was planted by the Abbot in the reign of Stephen, about 1140. Prior John, of Spalding, in Lincolnshire, planted vineyards, as did the Abbots of Denny Abbey, Cambridgeshire; likewise the Abbey of Bury St. Edmund's, in Suffolk, had a vineyard among its appurtenances, and the Priory at Dunstable, in Bedfordshire, founded by Henry I., had a vineyard attached to it. Most of the Barons of this period possessed vineyards and made their own wine. The hills at Godalming, in Surrey, and the Hampshire Downs were clad with Vines. Kent had vineyards—those of the Abbey of St. Augustine and the Priory at Canterbury. The valley of the Severn, according to William of Malmesbury, about 1148, at Gloucester, was the chief wine-producing district in England, there being "more vineyards and better Grapes grown in that county than in any other part of the country."

After the time just mentioned disputes arose with the ecclesiastics, and the country engaged in foreign wars, which led to the decline and fall of Grape Vine culture and of wine making in England. Still, in the reign of Henry III., British grown Grapes made excellent native wine, and the Bishop of Rochester sent Edward II. a present of "both wine and Grapes of his own growth at his vineyard at Halling." Then, for about 300 years, the fashion was for foreign wines—the produce of English provinces in France; yet home-made wine must have found some favour, for in the sixteenth and seventeenth centuries vineyards were in vogue. The first Earl of Salisbury made a vineyard at Hatfield House, Hertfordshire, about the year 1605, and Dr. Ralf Bathurst made excellent claret from Grapes grown at Oxford in 1685. On the slope of a hill at Dorking, in Surrey, Grape Vines were grown successfully for many years, but Defoe found "the vineyards at Deepdene neglected" in 1726. Dr. Shaw, however, grew Vines at Kensington so well that the vintage "equalled the lighter wines of France." At Cobham, in Surrey, on the warm, gravelly, and dry soil of Pain's Hill, Grapes were grown, and made into "champagne," by the Hon. Charles Hamilton. Collinson, in 1748, says, "a considerable quantity of wine will be made this year in England—my vineyard Grapes are very ripe" (October 3rd). In 1763 the Duke of Norfolk's cellars at Arundel Castle, Sussex, contained sixty pipes of English Burgundy, "better than imported," which was made from the Duke's vineyard produce. After 1790 vineyard Grapes appear to have again fallen into disfavour—that is, gone out of fashion, the blame being cast on a cycle of cold wet summers, when "vineyard Grapes ceased to yield good vinous juice for a period of twenty-five years."

Thus the art of growing Grapes in vineyards and that of making excellent wine in England appears to have been lost about a century ago. Wine, however, was still made from English outdoor-grown Grapes by the old-fashioned utilitarian viticulturists of the nineteenth century, but they were the exception rather than the rule, and vineyards were only mentioned as relics of the past. After the middle of the present century there seems to have been a re-awakening, for in the fifties, if I remember rightly, "Upwards and Onwards" detailed his experience in growing outdoor Grapes and making wine from them in the *Cottage Gardener*. The wine was "better than imported." Was this fact the prompter of the vineyard in the valley of the Taff, at Castle Coch, in Glamorganshire? Did the success of this Welsh vineyard of the nineteenth century lead to the establishment of that at Swanbridge, which "was calculated to produce a vintage of 25 or 30 hogsheads of wine" in 1897 (*Journal of Horticulture*, October 24th, 1897, page 357)?

From the facts to hand it appears that the climate of England and Wales was as good or better from the middle of the present century as in the time of the Normans and Romans for growing Grape Vines in the open, and the Grapes from them for making palatable wine. I say *better*, for at the Roman period immense tracts of country were fens, marshes, and swamps, and though the conqueror of the world did much to improve Britain and the Britons, there remained much to be done in the way of draining and reclaiming land at and after the Norman conquest. Hence the whole land must now, from the great improvements that have been carried out, be warmer and drier than in Roman, Anglo-Saxon, Norman, and up to

the reign of George III., when vineyards in England fell into abeyance, and the wars caused by the French revolution (1795-1814) led to an extraordinary improvement in agriculture all over the country through the high price of agricultural produce. Still the fact remains that the alterations would improve the climate of this country rather than make it colder or wetter, hence more suitable than it had ever been in historical times for the outdoor cultivation of the Grape Vine and the produce thereof capable of making wine.

Now that land cannot, according to the prevalent ideas and practices of agriculturists, be made to pay under ordinary crops, why not devote a portion to vineyards? We have it on record that Sir Henry Littleton made excellent wine from Grapes grown in a warm nook at Over Ashby, in Staffordshire. Begin there, or at the Trent, in the southern part of Derbyshire, and let that point express the northern limit of vineyard experiments to be instituted. Let sunny slopes—such as are too steep for ordinary agricultural or horticultural purposes—be selected, terrace the sites so as to facilitate cultural operations and catch or hold rains in summer, with grips to run off the superfluous water in winter, and on these demonstrate that the climate of England has not declined in temperature or the soil of this country deteriorated in respect of the growth of Grape Vines and the Grapes they produce for making wines of full body and rich bouquet. Make choice of the gravelly or sandy and dry soils that now grow scarcely anything but worthless scrub, and see how Grape Vines will flourish. Make no question about sites—there are thousands awaiting the husbandman to make them smile with plenteousness of fruit and wine. The Neve, the Welland, the Great Ouse, the Severn and its tributaries, the Lea, the Thames, the Medway, the Stour, the Arun, and many other rivers of the southern part of England and Wales, still flow on, their courses deeper, their slopes less slanting, and the hills they drain not much lower, while the soil of the valleys remains as rich, or richer, as in bygone times.—G. ABBEY.

(To be continued.)

WELL RIPENED ONIONS.

I AM sending you a sample of Ailsa Craig Onions, grown by Mr. James Riddell, gardener to T. G. Gibson, Esq., Lesbury House. Some little time ago, when at Lesbury, I saw a lot of splendid Onions, large in size, excellent in form, and, from the way they were keeping, giving every evidence that they had been thoroughly well ripened. Mr. Riddell is an "expert" in Onion growing, and not only carries off the first prize annually for Onions at the Alnwick Horticultural Society's Show in September, but never fails to produce a crop of fine large well-finished specimens. Many prefer small Onions to large ones, and one of the reasons often given is that they keep better; but you will see from the enclosed that even in Northumberland bulbs can be grown to a good size and keep well. Mr. Riddell's plan is to sow the seed under glass in January, and grow the plants in boxes until planting out time.—N. N.

[The Onions received are remarkably fine, true to name, and solid. Their keeping properties shall be further tested. Large Onions are objected to by economical cooks, because when they only want an ounce or two they do not like to spoil a bulb weighing a couple of pounds by taking a slice off it. For ordinary culinary purposes they prefer to have variously sized Onions to pick from. Commercially speaking, Great Britain pays some £750,000 a year for imported Onions, many of which are not equal to the samples before us as grown in Northumberland.]

THE SEASON AND THE FLOWERS.

SOME time ago a friend in a border county wrote, "The wood is white with the Snowdrops I planted." Later he said, "Crocuses are of no use; the bloom is completely spoiled." Considerably farther north the Snowdrop had but a poor time of it, and the Crocus was blown, battered, and frozen unmercifully; the yellows made some appearance, although often peering through a covering of snow: the latter colours were seen and little more, being caught in a spell of weather compounded of samples of every sort except the mild and genial. Scillas have braved it fairly well, and the bright eye of the *Chionodoxa* still sparkles in the chilly blast. But a more unfavourable season for flowers could scarcely be imagined; the biting north winds and frosty nights make their struggle a hard one. The Tulip stands still, and even the *Auricula* under protection scarcely advances, the truss being now much where it was three weeks ago. At the present rate of progress the general bloom of this flower will be in June.

Outside, the flower of the Daffodil seems to cower among the foliage, which is yet scanty enough, that of the Barri and Leeds section looking especially attenuated both in those planted last autumn and of the longer established beds. With a change to more favourable weather the later Daffs might yet do fairly well, but in any case the bloom must now be a light one. Is it to tantalise, or ought one rather thankfully to accept it as a compensation, that the colour seems richer than usual? Rarely has *pallidus præcox* been so fair; seldom has Sir Henry Irving donned a richer robe, or Golden Spur been so worthy of its name.—A NORTHERN AMATEUR.

FIGS IN POTS.

It is surprising what an amount of feeding Figs in pots will take when healthy and full of fruit. Though when started early in the year they seem to have ample room in the pots, it soon becomes evident that something more is needed when the crop on the young shoots begins to swell. Some pot trees of St. John's Fig pinched a week since are now pushing up the fruit. They had a thorough top-dressing of rich loam, an artificial rim of this material being packed round just inside the rim of the pots, and in less than a fortnight the roots pushed through this in all directions, searching out the bonemeal that was sprinkled among the loam.

I am sure there is no more fruitful cause of the Figs dropping when half grown than starvation treatment combined on occasions with over-cropping. The work a healthy well-cropped Fig tree has to do at this season is considerable, and the roots eagerly search for whatever is given in the way of food. Observation of this should show cultivators when the feeding is needed, for the tree reads one as plain a lesson as possible. Another very frequent cause of failure with forced Figs is keeping them thickly placed in warm, moist houses, and before properly hardening, turning them out in the full sun. The leaves are then often browned and scorched, so cannot perform their due functions, and this is a serious check to the trees.—B. S. E.

ROYAL HORTICULTURAL SOCIETY.

DRILL HALL.—APRIL 18TH.

It is more than probable that a better display than that presented at the Drill Hall on Tuesday has never been excelled for beauty and interest at this season of the year. The number of entries was remarkably high, and, so far as flowers and foliage plants were concerned, there were variety and excellence of quality in an exceptional degree. Narcissi made a show in themselves, as did Roses and gorgeous Tulips. Orchids again easily maintained the high standard that is now expected at these meetings. Save for Mr. Bunyard's splendid collection of Apples the Fruit and Vegetable Committee had little before them.

FRUIT COMMITTEE.—Present: P. Crowley, Esq. (in the chair); with the Rev. W. Wilks, and Messrs. R. Parker, J. H. Veitch, J. Cheal, W. Poupert, E. Shaw-Blaker, A. H. Pearson, W. Pope, A. Dean, S. Mortimer, W. Farr, G. Woodward, C. Herrin, W. Bates, F. Q. Lane, A. F. Barron, W. J. Empson, G. Wythes, H. Balderson, W. H. Divers, J. Willard, and R. Fife.

Messrs. G. Bunyard & Co., Maidstone, staged a magnificent collection of Apples in about one hundred dishes. All of the varieties were in splendid condition, illustrating once again the capabilities of the Maidstone fruit room. Early and late sorts were represented, and received at the hands of the Fruit Committee a silver-gilt Knightian medal.

Mr. S. Mortimer, Farnham, contributed a dozen boxes of Tomatoes all of a new variety named Winter Beauty. One box contained the bunches of fruits and the other single specimens, but all alike were of great excellence. Mr. G. Wythes, gardener to the Duke of Northumberland, Syon House, sent grand Figs Pingo de Mel and St. John, and some splendid Asparagus from open air beds. Mr. W. J. Empson, gardener to Mrs. Wingfield, Ampthill, sent Pea Carter's Early Morn, which ought to be of value for early use.

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair); with Messrs. J. Fraser, C. T. Druery, O. Thomas, H. B. May, R. Dean, J. H. Fitt, G. Nicholson, W. Howe, J. Jennings, R. B. Lowe, T. Peed, R. W. Ker, J. Fraser (Kew), G. Paul, W. Bain, J. D. Pawle, C. A. Fielder, H. J. Cutbush, J. W. Barr, E. T. Cook, E. Beckett, T. W. Sanders, D. B. Crane, E. H. Jenkins, C. Blick, H. S. Leonard, H. J. Jones, H. Turner, and E. Mawley.

An attractive semicircular group was arranged by Mr. H. B. May, Upper Edmonton. It comprised Crimson Rambler Roses, Spiræas, and Hydrangeas, with Acers and Ferns. The plants were carrying excellent flowers. A bright exhibit was that contributed by Messrs. J. Carter & Co., High Holborn. It consisted wholly of Cinerarias, single varieties, dwarf and bushy in habit, and carrying flowers of high quality, and doubles not so diversified in colour, but equally attractive and interesting. Mr. Brown, gardener to Sir Francis Berry, St. Leonard's Hill, Windsor, staged a collection of Camellia flowers cut from plants growing in the open ground. The varieties numbered forty, and the colours were rich and clear. The large stout foliage was deep green in hue, and spoke of the rudest health. They will go far with visitors to demonstrate the hardiness of the Camellia.

The 130 pots of Dutch Tulips, representing 160 varieties, sent by Messrs. W. Paul & Son, Waltham Cross, lent colour and attractiveness to the exhibition. The flowers were not particularly large, but they were of rich colour, and rose above healthy leafage. All the best known double and single varieties were represented, and this fact makes the mention of names unnecessary. Mr. R. Fyfe, gardener to Lord Wantage, V.C., Lockinge Park, Wantage, exhibited a number of blooms of Fortune's Yellow Roses. They were of superb quality, large in size, and rich in colour. It is seldom that this Rose is seen in such splendid condition. Mr. G. W. Piper, Uckfield, sent Tea Rose Sunrise—a variety exceptionally rich in colour, and of good form. Messrs. R. Wallace & Co., Colchester, were represented by a small collection of flowers, including Fritillarias, Erythroniums, Irises, Anemones, and others.

Mr. J. Arkwright, Hampton Court, Leominster, staged a number of plants of Primrose Evelyn Arkwright, a large flowered variety that is now comparatively well known. The same exhibitor also showed a small collection of Primulas. Messrs. Sutton & Sons, Reading, sent a group of

Cineraria stellulata, representing a wider range of colour than is commonly seen. It may reasonably be expected that when these become better known they will be accorded a very large share of popularity for their graceful habit and the splendid lasting properties of the flowers. Mr. J. Russell, Richmond, contributed a small group mainly composed of Azaleas, Staphylea colchica, Lilacs, and Wistaria sinensis. Mr. Bain, gardener to Sir Trevor Lawrence, Bart., Dorking, showed some magnificent Anthuriums, with a few Begonias.

Indian Azaleas from Messrs. R. & G. Cutbush, New Southgate, made a brilliant stand, and attracted much admiration. The varieties were fairly numerous, and the colours ranged from pure white to the deepest crimson. Messrs. G. Jackman & Sons, Woking, sent an interesting exhibit, largely composed of Primulas, but including also Daffodils and hardy herbaceous flowers. Mr. D. Kemp, gardener to W. Bryant, Esq., Stoke Edith Park, Slough, was represented by a collection of Amaryllis (Hippeastrums). The plants were very large, and producing immense leaves and spikes of grand flowers. The miscellaneous plants from Messrs. W. Cutbush & Son, Highgate, were very charming, and merited the admiration they received. There were Ericas, Oranges, Boronias, Acacias, and others.

Mr. W. Rumsey, Joynings Nurseries, Waltham Cross, made a most attractive display with Roses, both on plants and in boxes. The plants in pots were clean and healthy, and carrying richly coloured, while the blooms in boxes were well above average merit. Messrs. B. S. Williams & Son, Upper Holloway, exhibited in a large group of miscellaneous flowering and foliage plants some magnificent Vandas, Ericas, Clivias, Acacias, Ferns, Palms, and others. Messrs. Paul & Son, Old Nurseries, Cheshunt, sent Roses in pots—small plants carrying fine flowers—and also Rosa Wichuriana variegata, a variety that will evidently travel a considerable distance in one season.

Messrs. J. Peed & Son, Roupell Park Nurseries, Norwood, showed a group in which such foliage plants as Caladiums, Dracenas, Ferns, and Asparagus were most prominent. Messrs. J. Laing & Sons, Forest Hill, made a very bright display with various plants. Amongst the most conspicuous were Azaleas, Ericas, Clivias, Lilioms, Boronias, Cyclamens, a few Orchids, with numerous foliage plants. Messrs. J. Veitch & Sons, Ltd., Chelsea, sent some splendidly flowered plants of Spiraea astilboides compacta. Messrs. Collins Bros. & Gabriel, Waterloo Road, staged a large collection of Polyanthus.

ORCHID COMMITTEE.—Present: H. J. Veitch, Esq. (in the chair); with Messrs. J. O'Brien, S. Courtland, J. Colman, E. Ashworth, W. H. White, E. Hill, H. T. Pitt, J. Jaques, F. J. Thorne, F. Sander, T. W. Bond, W. H. Young, A. Outram, H. Little, J. T. Gabriel, H. J. Chapman, H. Ballantine, de Barri Crawshaw, J. G. Fowler, and T. B. Haywood.

Mr. W. A. Bilney, Fir Frange, The Heath, Weybridge, showed a small collection of Orchids, in which Dendrobiums were attractively conspicuous. The exhibit also included Cattleyas, Cypripediums, Phaias, and Cymbidiums. For the fourth year in succession Mr. F. J. Thorne, gardener to Major J. Joicey, Sunningdale Park, staged splendidly flowered plants of Epidendrum (Diacrium) bicornutum, together with a few other admirably grown Orchids. Messrs. Hugh Low & Co's group of Orchids from Upper Clapton was very bright, and contained many splendid flowers. There were Odontoglossums, Dendrobiums, Cattleyas, and others, all in first-rate condition. The Cymbidium Lowianum in the group from Mr. Whiffen, gardener to J. Bradshaw, Esq., Southgate, were finely grown. This exhibitor sent also some Odontoglossums in good variety, as well as other Orchids.

Mr. W. H. White, Orchid grower to Sir Trevor Lawrence, Bart., was represented by a very effective group. There were Odontoglossum Andersonianum, O. coronarium miniatum, O. Edwardi, O. Ruckerianum, Calanthe veratrifolia, Miltonia cuneata grandiflora, Cymbidium Devonianum, and several others. The most attractive exhibit in the Orchid section was that from Messrs. J. Veitch & Sons, Ltd., Chelsea. The several plants of which the group was composed were in the best of health, and represented some of the best Orchids now in bloom. We cannot name all, but may mention Cattleyas, Dendrobiums, Miltonias, Calanthes, Oncidiums, Cymbidiums, Epidendrums, Lælias, Cypripediums, and Odontoglossums as amongst the most prominent.

Mr. H. Ballantine, gardener to Baron Schröder, The Dell, Egham, sent some superb spikes of Odontoglossums, and several other growers contributed to the display by sending small exhibits.

NARCISSUS COMMITTEE.—Present: The Rev. G. Engleheart (in the chair); with Miss Willmott, and Messrs. J. Walker, A. Kingsmile, G. S. Titheradge, S. A. de Graaff, R. Sydenham, P. R. Barr, J. Pope, and A. Scrase Dickens.

Messrs. Barr & Sons, Covent Garden, showed a comprehensive display of Daffodils, beautifully staged with their own foliage. The collection comprised Mrs. Norma Crosfield, Madame Plomp, incomparabilis plenus, Glory of Leiden, cernuus, Catherine Spurrell, Victoria, Sulphur Phoenix, Mrs. Langtry, Orange Phoenix, Weardale Perfection (a fine form), Red Coat, Duke of Bedford, Dr. Fell, and intermedius Sunset.

Messrs. T. S. Ware, Ltd., Tottenham, staged a good collection of hardy spring flowers, consisting of Daffodils, such as Emperor, Victoria, Madame Plomp, Horsefieldi, Madame de Graaff, albicans, and Sir Watkin; Primulas Sieboldi, lilacina, denticulata, and S. rosea striata, with a good strain of Polyanthus, Erythroniums, Violet sulphurea odorata, and Adonis vernalis. Messrs. J. Veitch & Sons, Chelsea, exhibited a pretty table of Daffodils, arranged with pots of Maidenhair Fern. The chief forms were Princess, Empress Victoria, Emperor, Horsefieldi, Burbidgei, Flora Wilson, C. J. Backhouse, Princess Ida, Fred Moore, Sir Watkin, and Golden Plover. The flowers presented a very bright and spring-like appearance.

Messrs. Pearson & Sons, Chilwell, Nottingham, also staged a display of fresh bright blooms, arranged in a very free style, which contributed to make up a good effect. The following forms were particularly noticeable—Leedsi superbus, maximus, Princess Ida, Empress, Her Majesty, Queen Bess, albicans, Minnie Hume, Horsefieldi, Santa Maria, and triandrus albus. Mr. R. H. Bath, Ltd., Wisbech, contributed a capital collection of Daffodils, the flowers were large, well coloured, and very fresh. The chief forms were Victoria, Madame Plomp, Horsefieldi, maximus, Wm. Goldring, M. J. Berkley, Mrs. Thompson, Mrs. W. T. Ware, Queen of Spain, cernuus puleher, Empress, Grand Duchess, and Barri conspicuus.

Mr. J. W. Jones, Invermore, Woking, staged a pretty little group of Daffodils, comprising such forms as Sir Watkin, Empress, Queen Bess, Emperor, cernuus, Mrs. Elwes, Minnie Hume, and Beauty. The Rev. G. H. Engleheart, Appleshaw, Andover, exhibited a group of hybrid and seedling Narcissi, which comprised many fine forms; Herrick, Sidney Edmond's White, Dubloon, Cassandra, a grand form of the poeticus type, the white being clear and satiny, Chaucer, Juliet, and Mistrel of the same type, were also very conspicuous. Mr. Bennett-Poe, Homewood, Cheshunt, staged a choice collection, including Duchess of Brabant, Edward Hart, Frank Miles, Sims Reeves, maximus, and Jessica.

MEDALS.—Fruit Committee: Silver-gilt Knightian medal to Messrs. G. Bunyard & Co. Floral Committee: Silver-gilt Flora medals to Messrs. H. B. May and J. Laing & Sons; silver Flora medal to Messrs. Sutton & Sons, and silver Banksian medals to Messrs. J. Carter & Co., W. Cutbush & Son, D. Kemp, and R. Brown. Orchid Committee: Silver-gilt Flora medal to Messrs. J. Veitch & Sons, Ltd.; silver Flora medals to Messrs. W. H. White, B. S. Williams & Son, H. Ballantine, and J. Bradshaw; and silver Banksian medals to Messrs. H. Low & Co., W. A. Bilney, and F. J. Thorne. Narcissus Committee: Silver-gilt Flora medal to Messrs. Barr & Sons; silver Flora medal to Messrs. J. Veitch & Sons; and silver Banksian medal to Messrs. R. H. Bath, Ltd.

CERTIFICATES AND AWARDS OF MERIT.

Anemone blanda cypriana (W. H. Divers).—A lovely dwarf plant, producing pure white flowers with a reverse of bright blue (first-class certificate).

Anthurium Perfection (W. Bain).—A magnificent plant, with large fiery scarlet spathes (first-class certificate).

Dendrobium Cliv. *Vine House variety* (A. Warburton).—A grand variety of the type; the sepals and petals are very rich in colour (award of merit).

Erythronium Johnstoni (R. Wallace & Co.).—This Dog's Tooth Violet has medium sized flowers of a bright rose colour (award of merit).

Masdevallia Shatttryana, *Chamberlain's variety* (W. H. White).—A lovely Orchid, of which the colour is clear mauve spotted with crimson at the base, the tails are yellow (first-class certificate).

Narcissus Pope's King (Pope & Son).—A superb variety of pure yellow colour; the large trumpet is very deep (award of merit).

Narcissus intermedius Sunset (Barr & Sons).—This is of the small cupped section. The perianth segments are yellow and the crown orange (award of merit).

Narcissus Duke of Bedford (Barr & Sons).—A superb bicolor; the trumpet is of immense breadth and substance (award of merit).

Narcissus Brigadier (G. H. Engleheart).—A refined bicolor; the broad perianth segments are pale cream and the crown bright yellow (award of merit).

Narcissus Edmonds' White (G. H. Engleheart).—One of the medium cupped section. The perianth segments are white, and the fringed cup lemon yellow (first-class certificate).

Narcissus Cassandra (G. H. Engleheart).—A superb variety of the poeticus section. The colour is pure white, and the edge of the crown dark crimson (award of merit).

Narcissus Strongbow (G. H. Engleheart).—A striking form. The colour is pure white and bright yellow (award of merit).

Narcissus Flambeau (G. H. Engleheart).—A very bright flower, especially the crown, which is brilliant orange scarlet. The perianth segments are yellow (award of merit).

Odontoglossum Andersonianum obtusifolium (C. J. Lucas).—This variety has a cream ground colour with spots and patches of dull brown (award of merit).

Odontoglossum Andrianæ Lady Wigan (W. H. Young).—The basal colour of this variety is cream, and the whole of the flower is profusely spotted with bright brown. The sepals and petals are wavy in outline (award of merit).

Odontoglossum crispum Ashworthianum (H. Holbrook).—This is a superb variety. Almost the whole of the upper sepals and petals are dull crimson with white edges; on the lower sepals and the heavily fringed lip there is more white (award of merit).

Pea Carter's Early Morn (W. J. Empson).—A dwarf growing variety that is valuable for early cropping (award of merit).

Tomato Winter Beauty (S. Mortimer).—A free cropping variety producing medium-sized fruits of bright scarlet colour. The flavour is very good (award of merit).

THE MIDLAND DAFFODIL SOCIETY.

APRIL 13TH AND 14TH.

THE initial show of this Society was held under somewhat unpropitious circumstances so far as the weather was concerned; but there was a large attendance of visitors on the first day to enjoy, perhaps, the best exhibition of its kind ever held in the Midlands. Unfortunately, the

almost continuous fall of rain on the second day adversely affected the attendance. Fears had also been entertained for some weeks past that the wintery weather of March would materially affect the exhibition, but these were not realised, as the whole of the space was filled to repletion, and the honorary and trade displays being even more *en evidence* than at any spring show yet held in the Edgbaston Botanical Gardens. In the evening of the first day Mr. R. Sydenham entertained the judges and others to a dinner.

A Daffodil conference, presided over by the Rev. G. H. Engleheart, held in the library of the Botanical Gardens on the morning of the second day, was well attended, and various suggestions were submitted and debated regarding the future arrangements of the Society, as well as an instructive discussion on the culture and hybridisation of the Narcissi. The Rev. G. H. Engleheart's large stand of hybrid Narcissi was an object of much attention, and F.C.C.'s were deservedly awarded to three new seedlings of high merit—viz., Edmond's White, having a fine yellow trumpet, with an excellent white perianth; Firefly, a name suggested by the brilliant red cup, and the perianth composed of pure white; and Incognita, a remarkable flower, with a very large white perianth, and wide, rich orange-red cup. The two latter varieties were of the Poeticus section. A F.C.C. was also deservedly awarded to Messrs. Barr & Sons' Duke of York, almost a second Weardale Perfection.

CUT BLOOMS.—There was only one entry in the class for a collection of Narcissi, not less than fifty varieties (not to include the Polyanthus section), representing the three groups—Magni Coronati, Medio Coronati, and Parvi Coronati, one vase only of each variety, containing not less than two or more than twelve blooms, and the first prize, an elegant silver cup, value £7 7s., offered by Messrs. Barr & Son, London, was awarded to the Rev. J. Jacobs, Whitechurch, Salop, for an excellent exhibit. For twelve distinct varieties of true Trumpet Daffodils (not less than three or more than five blooms of each) the first prize was awarded to Mr. W. J. Grant, Newport, Mon., and the second to Messrs. John Pope & Son, King's Norton Nurseries, and the third to Mrs. M. B. Crawford, Ardnamont, Kyles of Bute. For six varieties the first prize was secured by J. C. Williams, Esq., Caerhays Castle, St. Austell; the second by R. Cartwright, Esq., Selby Park, Birmingham; the third by Miss Fanny Currey, Lismore, Ireland; the fourth by P. D. Williams, Esq., Lanarth, St. Keverne; and the fifth by Mr. J. T. White, Spalding. There were thirteen exhibits, and the blooms in the first and second prize stands especially were of grand quality.

For twelve distinct Medio Coronatis Miss F. Currey was to the fore with an excellent exhibit; the second prize being awarded to Mr. W. J. Grant; the third to P. D. Williams, Esq., and the fourth to Messrs. John Pope & Son. For six distinct varieties, Messrs. J. C. Williams, St. Keverne, H. B. Young, Lincoln, R. C. Cartwright, R. T. Mills, Tipton Grove, Chesterfield, and J. Mallender, Hodsock Priory, Worksop, Notts, were awarded the prizes in the order named.

In the class of twelve Parvi Coronatis, Messrs. W. J. Grant and Isaac Cooke, Shrewsbury, were respectively first and second prizetakers, and were the only representatives, their blooms presenting a very pretty and chaste effect. For six varieties the first prize was awarded to Mr. P. D. Williams, the second to Miss F. Currey, the third to Mr. J. C. Williams, and the fourth to Mr. R. C. Cartwright.

For twelve varieties of Tulips, arranged for effect, six blooms in a bunch, with their own foliage, Messrs. R. C. Cartwright and Robert Sydenham were the respective winners, with excellent examples. For six varieties Miss E. M. Sharp, Edgbaston; Mr. J. Sceany, Harborne; and Mr. A. Cryer, gardener to J. A. Kenrick, Esq., Edgbaston, were the prizetakers in the order named. Mr. R. Sydenham (the only exhibitor) was awarded the first prize for a collection of Spanish Irises arranged for effect.

PLANTS GROWN IN POTS.—For twelve pots of any varieties of Daffodils (Polyanthus section excluded), the first prize was easily won by Mr. R. Sydenham with an excellent exhibit. Messrs. Isaac Cooke, A. Cryer, and A. W. Hulse, Beech Lane, Edgbaston, were placed as in the order named with good examples. For six pots Mr. R. C. Cartwright secured the first prize and an "award of merit," the second position falling to Mr. G. Stacey, gardener to Mrs. Whitmore, Edgbaston; the third to Mr. J. Sceany, the fourth to Miss E. M. Sharp, and the fifth to Mr. C. Knight, Harborne. For six pots Polyanthus Narcissus the respective winners were Mr. R. Sydenham, Mr. Isaac Cooke, Miss E. M. Sharp, Mr. A. Cryer, and Mr. G. Stacey.

For six pots single Tulips, distinct, Messrs. R. Sydenham, A. Cryer, R. C. Cartwright, and G. Stacey were placed in the order named. Lilies of the Valley proved an attractive feature, and for six pots, not exceeding 7 inches in diameter, the first prize was awarded to Mr. A. Cryer, the second to Mr. I. Cooke, and the third to Mr. R. Sydenham. For six pots of Cyclamens the first prize was secured by Mr. E. J. Mustin, gardener to A. F. Bird, Esq., Moseley, and the second to Mr. Isaac Cooke. For six pots of Liliun Harrisii the only exhibitor was Mr. A. Cryer, with excellent examples, and to which the first prize was awarded. Cinerarias formed a very attractive feature. For four pots Messrs. E. J. Mustin, A. Cryer, and I. Cooke were the respective winners.

For Mr. R. Sydenham's prizes for three bowls or jars of Polyanthus Narcissus, grown in cocoa-nut fibre without drainage, the first prize was awarded to Mr. J. Cooke, the second to Mr. R. Sydenham, and the third to Miss E. A. Sharp. For any other variety of Daffodil the prizes were awarded as in the previous order. For Messrs. Thomson & Co.'s special prizes for six Cinerarias in pots, Messrs. E. J. Mustin, A. Cryer, and A. W. Hulse were the respective winners. For four Calceolarias in pots Messrs. E. J. Mustin and A. Cryer had splendid examples, both in foliage and bloom.

Table decorations, 6 feet by 3 feet, arranged with any varieties of cut Daffodils and foliage, formed a very attractive feature. The first prize was easily taken by Messrs. Pope & Sons with an elegant arrangement, and the second and third prizes to Mr. E. J. Mustin and Miss E. C. Swinden, Edgbaston. For a group of cut Daffodils or Tulips arranged on a round table, suitable for a hall or drawing-room, Miss Swinden was the first, Mr. Seeany the second, and Mr. E. J. Mustin the third prize winners. For a bowl of cut Daffodils Mr. R. Sydenham and Mr. A. Cryer were the first and second winners, while Miss Swinden secured the third prize. Bouquets of Daffodils were tastefully arranged, and Messrs. Pope and Sons were to the fore with a most graceful example, the second prize going to Mr. J. Cooke, and the third to Mr. A. W. Hulse.

HONORARY AWARDS.—Silver-gilt medal: Messrs. Barr & Sons, Covent Garden, for collection of Daffodils. Silver medals: R. H. Bath (Limited), Wisbech, collection of Daffodils; Messrs. Hogg & Robertson, Dublin, Daffodils and Tulips; T. S. Ware (Limited), Tottenham, Daffodils; Hewitt & Co., Solihull, floral decorations. First-class certificates: Dicksons (Limited), Chester, for Golden-leaved Holly Golden King; Rev. G. H. Engleheart, Appleshaw, Andover, for seedling Daffodils Incognita, Firebrand, Edmonds' White; Pope & Sons, King's Norton, for Primula obconica Snowflake; Richard Dean, Ealing, Campanula Balchiniana; Pope & Sons for Daffodil "Pope's King." Bronze medal: Simpson & Sons, Birmingham, collection of bulbous plants, grown in Jadoo fibre; Dicksons (Limited), for collection of Daffodils; R. Sydenham, collection of bulbous plants, grown in cocoa-nut fibre refuse and shell without drainage.

AURICULA AND PRIMULA SHOW.

APRIL 18TH.

THE exhibition of the National Auricula and Primula Society was held at the Drill Hall on April 18th, and proved a good show in every respect—in fact, it was much better than was expected by the exhibitors themselves.

In the class for twelve plants dissimilar, Mr. Jas. Douglas, Great Bookham, Surrey, was placed first with a very even exhibit. The varieties were Mrs. Potts, Highlier, Dinham, George Rudd, J. Hannaford, Acme, G. Lightbody, Teresias, Lady Churchill, Cleopatra, Venus, and Rachel. Mr. C. Phillips, Bracknell, gained the second position with a good display of greys, which included Black Bess, Acme, Rachel, Geo. Rudd, Miss Barnett, and Marmion. Mr. W. Smith, Bishops Stortford, was placed third with good plants of Lord Lorne, Heatherbell, Mrs. Dodwell, and Shirley Hibberd. Mr. P. Purnell, Streatham Hill, was fourth and Mr. P. Worsley, Clifton, fifth.

There were four competitors for six plants, dissimilar, Mr. C. Phillips securing first position with good plants of Mrs. Henwood, Black Bess, G. Rudd, Rev. F. D. Horner, Mrs. Phillips, and Acme. Mr. J. Sargent, Cobham, was a very close second with Ruby, Acme, and Rachel, good. Mr. W. Smith was third, and Mr. P. Purnell fourth. In the class for four dissimilar plants, Mr. Euston, gardener to Mrs. F. Whitbourn, Ilford, was placed first with four good plants. Mr. A. R. Brown, Birmingham, came second, and J. T. Bennett-Poë, Cheshunt, third. Mr. A. R. Brown was placed first for two plants, distinct, Mr. Euston taking second place; Mr. Bennett-Poë third, and Mr. R. Holding brought up the rear.

The single plants, green edged, brought out six competitors, and Mr. P. J. Worsley was placed first with the Rev. F. D. Horner, Mr. J. Sargent second with Abbé Listz, Mr. A. P. Brown third with a fine plant of Mars, Mr. W. Smith fourth with a good seedling. The competition in the grey edges was marked by a better display, Mr. W. Smith being first with a good plant of Rachel, the same exhibitor second with Geo. Rudd, Mr. Sargent third with Rachel. There were eight competitors for the white edges. Mr. A. R. Brown was placed first with Acme, Mr. F. Sargent second with Heatherbell, Mr. W. Smith third with Mrs. Dodwell.

The self class appeared to be very popular, no less than fifteen plants being staged. Mr. P. Hemmell was placed first with a good specimen of Heroine, Mr. Chas. Phillips came second with Mrs. Phillips, Mr. P. Purnell third with Mrs. Potts. For fifty Auriculas, not less than twenty varieties, Mr. Jas. Douglas was placed first with a capital exhibit; the chief varieties employed were Mrs. Potts, Rachel, Phyllis, Black Bess, Ruby, Venus, and Geo. Rudd. Mr. C. Phillips was second with an even exhibit, with good specimens of Yellow Leg, Mrs. Potts, Cecil Rhodes, Black Bess, Myra, and Richard Headley. The Hardy Plant Nursery, Guildford, was third with a very neat exhibit.

For twelve Alpines Mr. C. Phillips was ahead with a beautiful exhibit. Mrs. C. F. Barnett, Saturn, Gladys, Lady Clementina Walsh, and Mrs. Martin Smith appeared the best specimens. The Guildford Hardy Plant Nursery was second with well developed plants of Dean Hole, A. Maxwell, J. Gilbert, and Ganymede. For six Alpines, dissimilar, Mr. C. Phillips was first with Topsy, Myra, and Perfection. Mr. Euston came second with good bright colours, and Mr. Jas. Douglas third. For four plants, dissimilar, Mr. A. R. Brown secured first position. Mr. P. Purnell came second, and Mr. R. Holding third.

For twelve Fancy Auriculas the Hardy Plant Co. secured first place with good representatives of Old Gold, Russet, Innocence, Belle, and a few seedlings. Mr. Jas. Douglas was second with some good yellows, such as Safrano, Golden Oriole, Buttercup, and New Guinea. Mr. Euston third. For a single specimen of Alpines, gold centre, Mr. Chas. Phillips was first with Evelyn Phillips. The same exhibitor was second with the same variety, Mr. P. Purnell third with Dean Hole. In the class for single specimens, with a white or cream centre, Mr. C. Phillips was first with Perfection,

Mr. Phillips second with the same variety, Mr. J. W. Euston third with Echo.

For twelve Polyantheses, Mr. Jas. Douglas was placed first with a bright and varied collection. The same exhibitor was again successful in the class for twelve Primroses with some very distinct colours. Mr. P. Purnell was first for twelve Primula species, distinct, which comprised obconica, Sieboldi, denticulata alba, verticillata, and rosea. Mr. Jas. Douglas was first in the class for six species.

For a basket of Primroses, Miss Jekyll, Godalming, was placed first with a beautiful exhibit, composed of yellows and whites in varying shades. Mr. Jas. Douglas was third with a very good basket. For a group of Primulas or Auriculas, Mr. P. Purnell was well ahead with an exceedingly bright and varied exhibit. The Guildford Hardy Plant Nursery Co. were second, relying solely on Fancy Auriculas, in a good variety of colours.

THE YOUNG GARDENERS' DOMAIN.

A WORD TO THE WISE.

IN reading the articles in the "Young Gardeners' Domain" week by week one realises how few of the writers attempt to give the results of experience or discuss the various phases of vegetable production. I have more than once heard young men declare that all kitchen garden work can be "picked up" from such and such a publication. This, of course, can only emanate from those who have never given more than a passing thought to one of the most important aspects of the gardener's work. Remonstrance is often useless, but there surely comes a time when they wish their youth had not all been divided between the glass department and the pursuit of pleasure in leisure moments.

We must remember that, as a rule, the vegetable garden embraces a number of fruit trees, bush fruits, as well as Strawberries, besides which the greater part of the supply of cut flowers is expected to be obtained from this source during the summer months. In some instances this may not be so, I am aware, but the rule obtains, and happy is the man who is prepared for all emergencies. I will go further than this, and say that after making due allowance for the beauty and interest attaching to the ownership and cultivation of a good collection of Orchids, or splendid decorative plants, hothouse fruits, and the usual adjuncts of the modern glass establishments, the backbone of most places is the kitchen garden.

See in the spring how everything, where the department is well kept, teems with life, and what may be described as a "forward movement." How necessary is it for a man to be alert and ready! This is not the time for reference to books. To know and to do must be the order of the day if work is not to lag behind. In dry weather the hoe will be kept going, seeds will be sown, whilst in a showery time advantage will be taken for planting out and thinning growing crops. In the early part of the year provision will have been made for each successive occupant of the land—so much room for this, and so much ground for that. In summer and autumn comes the harvest, the ingathering of crops and the storing for use during the dark days of the year. What shall we say of winter! the time of all others when to the casual observer all seems flat and uninteresting. To the enthusiastic gardener it is nothing of the kind. Then is made one of the great efforts of all, for the days are short, time is precious. The weather, too, at that season often retards progress and causes work to be delayed. It is the season too, when the gardener seeks to put in order that "pantry" of plant life Mother Earth, by cultivation and the filling with all good things necessary for subsequent growth. The winter rain, the frost and snow, will aid; but the man must do his part, with the spade, with manure, and, let it not be forgotten, his brains.

"Take no thought for to-morrow," would certainly be poor advice for the kitchen gardener. He must prepare for this year and the next, and have, if possible a glance left for a look into another beyond that even. He learns according to the locality in which he may reside to make a rough calculation as to the weather. It may be far from correct, but it will often serve for a guide, whilst those who are less observant are caught. The really earnest man becomes somewhat of a chemist, and learns to know the action of different manures, both natural and artificial, and will find out what kinds suit his ground the best. Then there are the hundred and one pests, both feathered and insect, that infest gardens, and it will be wise to become acquainted with the best methods of preventing their attacks, and the surest remedial measures to be taken after the preventive stage has been passed. All this, and a great deal more, must the kitchen gardener be cognisant of ere he is worthy the name of such. Yet some of our young men tell us they can learn it all from books, and that easily.

Let none, however, misunderstand me. I do not decry the use of good works on gardening, quite the contrary. Happy is the man who has access to standard books on any given subject, and also to the periodicals which are published every week, and increase in numbers year by year. In this way a man keeps up to date, his ideas broaden and strengthen, or should do so, and thrice blessed is he who not only reads but can retain and assimilate. These few remarks on reading apply not only to work outside; in every branch of horticulture it is necessary to keep abreast of the times, and I care not who the man may be, if he observes nothing but what goes on inside his own garden walls, sooner or later he falls behind.

Of course, as there are different kinds of gardens, so there are all sorts of men in them. We see a man armed at all points, who, should a difficulty arise, will fairly stamp and trample the trouble out of existence. Such men know how important it is to be prepared for contingencies. If late spring frosts threaten breadths of early Potatoes, some means of

protection will be at hand in the shape of litter, or netting, mats, or anything which can be pressed into temporary service. So one might go on, but it is not in my province to enumerate the many instances in which the strong and persevering succeed and the weak and indolent fail. I might have enlarged on the subject of fruit, how one should become master of the knowledge of tree lifting, root pruning, and so on; all this comes to most of us sooner or later, and it is wise to be ready.—J. SHALFORD.

[Though still a "young gardener," our correspondent is now in a position of responsibility, and has, no doubt, experienced the advantage of the knowledge he advocates in the interests of young men who will sooner or later appreciate its value.]

FORMATION AND CROPPING OF A KITCHEN GARDEN.

WHERE the soil and locality are suitable the kitchen garden ought to be on the north side of the mansion. The principal walk leading from the pleasure grounds to the garden should be made as interesting and attractive as possible. The main entrance may be so chosen so that visitors get views of the most interesting and effective parts of the garden.

After selecting the site, which where possible should have a gentle slope towards the south. This point, however, is not an essential one, as we find many gardens entirely flat, yet under skilful management, they yield abundance of fruit and vegetables. The size or extent of the garden, like that of its distance from the mansion, must in a great measure depend on the taste of the owner, the number of family, and the demands of the establishment in general. The produce required will serve as a basis on which to form our future plans. It would not be possible to recommend one plan that would be applicable to all, as local conditions must be considered. When the outlines of the garden have been decided, the level of the ground or the slope thereof must be determined. I am greatly in favour of enclosing the garden within walls, as these afford shelter from cold winds, and thus provide protected borders that will be valuable for early crops.

Drainage is an operation which must precede trenching and other ground work. It sometimes occurs that land is naturally too dry when, of course, artificial drainage would be a mistake, but in most cases it is absolutely essential for the improvement of the soil and the subsequent benefit to the several crops. Before laying the main drains the principal walks should be marked out and the mains conducted under the centre of each one. The foundation of the walks can be made with whatever material may be at disposal, such as rough stones and broken bricks.

Walls that are to be used for fruit trees will require a border from 15 to 20 feet wide and 2 feet deep. For a south wall choose Peaches, Nectarines, Apricots and Figs; for a north aspect Morello Cherries, Gooseberries and Currants; for an east wall Pears, Plums and Cherries; and for a western aspect Apples, Pears and Plums. Fan-trained trees may be disposed 15 feet apart; horizontally formed 12 to 15 feet; and upright and diagonal cordons from 15 inches to 2 feet.

Apples, Pears and Plums may be cultivated as pyramids or half-standards, arranged round the central portions of the gardens, planting them from 15 to 20 feet apart and 4 to 6 feet from the walks, with bush fruits of Gooseberries and Currants planted alternately. Strawberries require a space of ground for their culture which should be properly prepared and manured. Select healthy and well-rooted runners in the autumn from fruiting plants, forming the rows from 18 inches to 2 feet asunder. Raspberries may be placed either in rows or clumps, and Gooseberries and Currants must also be provided, allowing a distance of from 9 to 12 feet from plant to plant. A suitable soil for fruit trees is a firm loam of medium texture, properly drained and well prepared. Top-dressings of lime, soot and wood ashes, and a quantity of mortar rubbish and charcoal, should be thoroughly incorporated with the soil. The greatest enemy to fruit trees is canker and gumming. As a means of prevention carefully plant healthy trees, encourage active fibrous roots near the surface, always keep the branches thinly disposed, so that the trees get the full benefit of the air and light, when they will eventually produce sound, matured and fortified growths. Avoid severe pruning, gross feeding, and over-luxuriant growth.

Before selecting the vegetable quarters make out a list of those which would be chiefly required, as this will serve as a guide in the arrangement of the ground at disposal. Each section may then be manured and deeply trenched, if the soil is deep enough to allow it, in accordance with the requirements of the crop that is to occupy it. If this work is done in the autumn the surface should be left as rough as possible.

The main object in view will be to maintain a supply of vegetables for as long a period as possible, and this will require a great amount of forethought and careful judgment. Deep working of the soil and systematic culture are essential, or the soil may be exhausted of its fertility long before it ought to be. The importance of doing all kitchen garden work thoroughly is shown more and more the longer it is practised.

I ought to refer to kinds and varieties as well as to cultural details on vegetables, but time forbids. I should like, however, to impress upon young gardeners that the reading of essays will not teach any gardener his work in the kitchen garden; such must be gathered from practical experience. Let us consider for a moment the collections of vegetables we find at our horticultural exhibitions. Such cultivation is not alone due to any special manures or choice seeds, but is generally the result, or I may say the essence, of untiring labour and strict attention in every detail of their culture, produced by skilful and intelligent management of men who possess both practical experience and perseverance.—(Abridged from the first-prize essay read by J. F. DONOGHUE, *Tranby Croft Gardens, Hull, before The Hesse Gardeners' Society.*)

FRUIT FORCING.

Vines.—Earliest House.—Early forced Vines usually contract red spider, when a timely washing of the leaves with a sponge moistened in a solution of soft soap—2 ozs. to a gallon of water, and with petroleum made soluble in it at the ratio of 1 fluid oz.—is the safest and best remedy, though rather a tedious process. Syringing, even between the bunches, with the clearest water spoils the appearance of the Grapes for market purposes, and employing sulphur on the hot-water pipes is sometimes attended with serious discolouration in white Grapes. Afford a thorough supply of water to the inside border, applying it early in the day, so that surplus moisture may pass off before closing time. A light mulch of dry material will prevent moisture arising prejudicial to the Grapes, but we use rather fresh yet well sweetened short litter from the stables, and it prevents the soil cracking and encourages surface roots. Early Grapes do not always colour well, the defect chiefly arising from overcropping, or continued hard forcing and attacks of red spider; it is only avoided by moderate cropping, rational treatment, and cleanly culture. A constant supply of rather dry warm air, but a comparatively low night temperature, will do much to assist heavily cropped Vines in colouring the Grapes. Where the Grapes are fully ripe a reduction in temperature is advisable, but 60° is essential to the after welfare of the Vines, and moderate moisture should be maintained for the benefit of the foliage.

Succession Houses.—The stopping and tying of the shoots must have attention. Where the space is restricted, stop the shoots two joints beyond the fruit; and as foliage is necessary to maintain root activity, leave the laterals on the shoot both above and below the bunch, or at least those from the two lowermost eyes, and those level with and above the bunch. Pinch these at the first joint, especially the ones from the basal leaves, also those above, unless there is space for extending the laterals, when they may be allowed to make two or three leaves, but no more growth must be encouraged than can have full exposure to light and air. After the space is fairly furnished keep the growth closely pinched to one joint as made. The great evil in Grape growing is overcrowding, which deprives the foliage of light and air, and restricting the growths is intended to avoid that and secure thoroughly solidified wood as it is made.

Tying Down.—It is a good plan to have the rods somewhat lower than the trellis, so that the side shoots have a slight incline upwards. In tying these in the places where they are to remain during the summer it is a common practice to begin to tie them down as soon as they are long enough to bend. This is not advisable unless as a precaution against injury from frost, as the shoots at this stage are so tender that the slightest twist the wrong way breaks them. It is a good method to defer tying down until the shoots are less sappy, which may be when the bunches are showing clear of the leaves or not until the shoots are stopped. Sufficient space should be left in the ligatures for the swelling of the growths. Stopping ought to commence when the leaf at the joint or place of pinching is the size of a halfpenny.

Vines in Flower.—Afford Muscats a free circulation of rather dry air, and a temperature of 80° to 85° or 90° by day from sun heat, 70° to 75° artificially, and 70° at night, falling 5° on cold nights. Raise the points of the bunches to the light, and liberate the pollen at midday by gently tapping the points of the bunches, or go over the bunches carefully with a large sized camel's hair brush, and afterwards dust them with another charged with Alicante pollen or that of some different and free setting variety. Hamburgs set freely in a lower temperature, but they are better for a little assistance from fire heat, say 60° to 65° at night, 70° to 75° by day, with 10° to 15° advance from sun heat, and other varieties are similarly aided during the flowering period.

Thinning Bunches and Berries.—It is advisable to make a selection of the best bunches, and leave only those required for the crop before they come into flower. This concentrates the forces on those retained, and by proper attention to fertilising the flower a good set and fine bunches are secured. Thinning the berries should commence as soon as they are set, especially in the case of the free setting varieties, and where fine specimens are required for exhibition it should be attended to whilst they are in flower. With the shy-setting sorts thinning should be deferred until the properly fertilised berries can be distinguished by their taking the lead in swelling. Remove surplus bunches, under rather than overcropping the Vines, as too heavy cropping is fatal to colour and finish.

Feeding.—When the Vines are in full leaf, and the Grapes swelling, they require abundant supplies of nourishment. Owing to the large extent of leaf surface the Vines evaporate enormous quantities of water under the influence of sunlight, and do most of the work then in assimilating the nutrient elements, the solid matters being left behind in the Vines, and with the carbonic acid gas derived from and fixed in the Vines as carbon, build up their structure solidly and healthfully. Stable, cow house, and manure heap drainings are excellent, being rich in available potash, and if a pound of mineral superphosphate be added to 30 gallons it is an advantage. The liquid must not be applied too strong, as an overdose injures, if not destroys, the young fibrous roots. Shankling also often follows packing the soil with organic matter held in suspension.

All the advertised fertilisers are excellent and handy. It is best to give the borders a thorough supply of water, then apply the fertiliser, and water in moderately. By this procedure there is no fear of losing any virtue the fertiliser contains, but when it is given on a dry border, and followed by a heavy watering, it is likely to be washed into the drainage, and roots be encouraged at the bottom of the border instead of near the surface. A light mulch of short, sweet, lumpy manure will be of advantage in keeping the border uniformly moist.

Late Houses.—The Vines are making rapid progress. Disbud and tie down the shoots as they require it. It is best to have the rods lower than the wires of the trellis, then the growths will only require tying out, and there is less danger of snapping, besides the shoots receive an equal supply of sap and have their points and the fruit-shows well up to the light. Close the house early in the afternoon with sun heat, and maintain plenty of atmospheric moisture by frequently damping the houses and syringing the Vines at closing time, but not after the bunches show. The latest houses of thick-skinned Grapes must now be started, giving them every encouragement to make growth, and set the fruit by the early part of June. Late Hamburgs are starting naturally, and need only have a little fire heat to exclude frost, but it is not advisable to allow the temperature to fall below 50°. Take care that the points of the shoots do not come into and remain in contact with the glass, or they may be scorched by sun or injured by frost.

Young Vines.—It will be necessary to afford a gentle fire heat in cold weather to keep the Vines in steady progress, otherwise they are best allowed to start naturally, and secure a short-jointed growth by free ventilation. Disbud, leaving the best shoots on both sides of the canes, and alternately at about 18 inches distance apart. The canes will have been depressed so as to cause them to break regularly down to the basal buds, when they can be tied in position. Crop lightly, one or two bunches being the maximum on permanent Vines. Any super-numeraries planted to fruit early, and afterwards be cut out, may carry a bunch on each shoot; six or eight bunches, however, are as many as vigorous Vines can bring to perfection.

THE KITCHEN GARDEN.

Kidney Beans.—The later crops of these in houses succeed best in long, narrow, moderately deep boxes. As pits or frames are cleared of early Potatoes these may be planted with Kidney Beans, raised in small pots in readiness. Mild hotbeds might in other cases be formed for growing Beans, with a view to relieving the houses of forced plants as quickly as possible. Hand-lights and rough frames ought also to be utilised for a similar purpose, abundance of early Beans never failing of appreciation. Two or three plants may be raised in each 3-inch pot, and they will make the best progress after they are planted if raised in gentle heat only.

Celery.—If the second early and maincrop plants are long left crowded in the seed pans or boxes they become spindly, and are slow in gaining strength. The earliest, or any wanted for planting out in May, are usually forwarded in frames over mild hotbeds; but in the case of successional plants that have been hardened in a cool house or frame, bottom heat may be dispensed with, though a little warmth at first is desirable. Set frames on a hard base, and in these place a layer, 5 inches deep after it has been trodden, of old hotbed manure not quite cold, and over this a thin layer of fine soil. Prick out the plants in this about 4 inches apart each way, arranging them in squares; give a gentle watering, put on the lights, and keep the plants close, shading from bright sun till they commence growing again. If kept well supplied with water the plants' progress will be fairly rapid, and in order to keep them sturdy admit abundance of light and air. When the time comes for moving them into the trenches they may be cut out each with a good square of soil and roots attached. Celeriac, or Turnip-rooted Celery, should be prepared similarly to ordinary Celery, only in this instance the final planting should be on the surface of good ground, not in trenches. If extra late Celery is desired, sow more seed now in hand-lights or boxes.

Onions.—Plants raised under glass, for providing handsome early bulbs, should be screened from cold easterly winds for a time after planting out. If raised thickly, and not pricked into other pans or boxes of soil prior to planting, the drawn plants should be lightly trimmed. Seed sown in the usual manner has germinated satisfactorily, and with favourable weather the plants will make good progress, especially if assisted by a dressing of soot between the rows. Nitrate of soda, applied carefully at the rate of 1 oz. to the square yard, also promotes a rapid, strong growth. There should be no undue delay in thinning the plants. They draw the most readily when quite small, and an early removal of all superfluous plants makes it much better for the rest. If the rows are 10 to 12 inches apart, and a heavy crop of medium-sized long-keeping bulbs are desired, leave the plants 3 inches to 4 inches apart, allowing an extra 2 inches if large ones are wanted. Good Onions for pickling may be obtained by sowing small silver-skinned sorts now, thickly and evenly on poor ground.

Parsley.—Large early raised plants are not the best for the winter crop, or for lifting and storing under glass. Sow seeds now, thinly in shallow moist drills, giving the preference to an open position. Thin out the earliest-raised plants lightly at first, and eventually to a distance of 6 inches or more apart. Plants raised in frames should have formed stout tap roots before they are transplanted to a well prepared border. They will be well ahead of the earliest sown in the open.

Salsafy and Scorzonera.—Roots of the best quality are usually obtained by sowing seed in April on ground that was well manured for a preceding surface rooting crop. If the tap roots come into contact with solid manure they fork badly. Draw drills 12 inches to 15 inches apart, and sow the seed thinly.

New Zealand Spinach.—During the hottest part of the summer the true Spinach is liable to run to seed prematurely, and a substitute in the form of New Zealand Spinach is appreciated in some establishments. A dozen strong plants, given good room on a sunny border, will usually provide enough tops for a single family, and these, or as many as required, should be raised under glass for planting out late in May. Sow the seed now, either two or three in each 3-inch pot, or in a pan or box of sandy soil, placing it in gentle heat.

Vegetable Marrow.—A few early Marrows may be obtained by growing one or more plants in a frame on a mild hotbed, allowing the haulm to spread when protection is no longer needed. Sow a few seeds singly in 3-inch pots and gentle heat, and commence collecting materials for the bed at an early date. Vegetable Marrows may be grown in boxes and trained up the roof of a house, Cucumber fashion, but the flowers must be fertilised.

THE BEE-KEEPER.

REARING YOUNG QUEENS.

ONE of the most important operations in connection with the successful management of bees is the rearing of young queens. In days gone by, when the majority of bees were kept in straw skeps, they were allowed to swarm, and thus a supply of young queens was easily obtained. But with the advent of the movable frame hive and our anxiety to obtain as much honey as possible by working the bees on the non-swarming system, queen rearing was often neglected. There are at the present moment many queenless stocks in the country which, if due precaution had been taken at the proper season, would now have had several frames filled with healthy brood in various stages of development and otherwise in good condition. It is, however, necessary that bee-keepers should have a system in managing their bees, otherwise it will end in failure. It is, however, so simple that it is surprising so important a matter should be left to chance. This is no imagination, as the many inquiries we have on this subject will prove. It is, of course, too early in the season to attempt queen rearing; but if the subject is brought before bee-keepers at this early date they can make arrangements in due course, and there will be less likelihood of neglect when the busy time in the apiary comes on.

COMMENCING OPERATIONS.

It is as well to remember that queens are at their best the second year. The bee-keeper should thus aim at having as many queens of the right age as possible. Another fact that should be borne in mind is the difference that often exists between the various colonies that have had exactly the same treatment throughout the previous season. The queens may all have been hatched at the same time and placed in strong stocks, or given extra bees to bring them up to the desired strength. Still, the following spring some of them will always be in much better condition than others.

Bearing these facts in mind, we always endeavour to have a given number of stocks as strong as possible by the time the honey flow comes. We therefore select those intended for honey production, and strengthen them, if necessary, with bees and brood from the hives intended for queen rearing. By these means colonies of great strength are obtained. Should one of them by chance swarm, which not 1 per cent. will do if due precaution is taken in ventilation and shading, the swarm is then placed in a separate hive, and the old stock used for rearing queens.

A few days afterwards examine the colony from which the swarm came and form nucleus hives from it, as a dozen or more queen cells will probably be found there. Care should be taken that there is a frame of brood in each hive, which ought to be placed between two frames of fully drawn out comb, that are well covered with bees. The advantage of having a frame of brood in each nucleus is that the bees will not desert the hive, which they will sometimes do when the young queen leaves.

We prefer fairly strong colonies for queen rearing, and the best time to commence operations is the middle of a fine day. Examine each frame until the queen is found, place the frame of brood and all the adhering bees with the queen in an empty hive, and close up with a frame of fully drawn out comb on each side. If there are not sufficient bees to cover the brood shake others into the hive from another comb, cover up warm and place the hive a few yards from its original stand, as it is not advisable to destroy the old queens until sufficient young ones are fertilised and laying. Queen cells will be at once commenced, young queens appearing on the sixteenth day. Three or four days previous to this divide the stocks into as many as required. If there are not sufficient queen cells the same operation must be again repeated by taking a frame of newly laid eggs from another hive. Each nucleus hive should then be treated in the same manner as recommended for a stock that swarmed.—AN ENGLISH BEE-KEEPER.

TO CORRESPONDENTS

•• All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," 8, Rose Hill Road, Wandsworth, S.W., and NOT to 12, Mitre Court Chambers, Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *nom de plumes* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Gloriosa superba (E. B.).—The bulbs should be potted without delay. They are best attended to in February, draining the pots well, and using a compost of loam and peat in equal proportions, with a free admixture of sand, and a "dash" of charcoal. Place in a house with a mean temperature of 70°, such as a Cucumber house or stove. Water carefully at starting, but when in full growth afford it liberally, never, however, overwatering, and afford all the light possible, giving the essential support to the stems. The usual atmospheric moisture must be provided. As the growth ripens withhold water gradually, and keep the soil dry during the winter. It is a good plan to lay the pots on their sides in a warm place during winter, as exposure to cold when at rest is a point especially to be avoided. These points—the seasons of growth and complete rest in a warm place—are the most important considerations in its culture.

Burrs on Spanish Chestnut (A. D.).—The burrs or knobs on the portion of stem are caused by a fungus, which we do not find sufficiently developed in your specimen for identification, but it has a close resemblance to that which produces burrs on sapling Ash, and may probably be a form of it—namely, *Dothiora sphaeroides*. The fungus chiefly fastens on the buds, destroys their growing points while in embryo, and lives in a sort of symbiosis in the root until its turn is served, causing it to swell abnormally at the affected part, sometimes for years, but ultimately breaks through the cuticular cells and then produces its "fruits," and the knobs afterwards assume a cankerous appearance. The cause is, of course, the fungus, and it is generally regarded as favoured by the saplings being allowed to grow closely or deprived of light and air, but we have found most specimens where the land is wet or the subsoil is cold and stubborn. Draining, open, of course, for woods and plantations, with a judicious thinning and removal of infested saplings, have been found the best preventives. The saplings are sometimes prized for walking sticks and when cut about the size of your specimen bring fancy prices.

Forced Strawberry Leaves Spotted (Festina Lento).—The leaves are affected by the Strawberry leaf blight fungus, *Sphaerella fragariae*, which is in some cases very disastrous. It first appears on the upper surface, in the shape of small purplish or reddish spots, which rapidly increase in size, and they often run together, thus extending over the whole or greater part of the surface and, of course, destroying the leaf. It usually begins in the summer time on the older leaves of the runners, and winters in them, and in the spring (winter in forced plants) or early summer passes as spores to the young leaves. The fungus appears to be gaining in the country. We have been much troubled with it, and found the practice of cutting off the old leaves, or those affected on the stock plant, and burning them, as soon as the fruit was gathered, very effective in lessening the disease another year. It is also excellent practice, but we have only carried it out on a small scale, after cutting off the old leaves and burning them, to spray with Bordeaux mixture at once, repeating early in September. Then, at starting, the old leaves that could be spared were removed and burnt, and the plants sprayed with Bordeaux mixture at half strength, repeating when the new leaves started, and again just before the flowers opened. This gave us excellent results. Before we pursued this treatment we could not get average crops of Keen's Seedling and many other varieties, they being eaten up by the fungus, as the spots on the leaves greatly impoverished the plants and prevented the fruit swelling properly. The thing is to begin with the early stages of the runners, and keep the parasite from them.

Vines not Setting the Fruit (A. B.).—There does not appear to be anything particularly amiss with the bunch and leaf, they, as you say, being quite healthy, but the "caps" adhere very tightly to the flower, and carry with them the stamens and anthers when removed. This does not indicate vigour, and certainly not a good set. We should have recourse to artificial impregnation, brushing the bunches over carefully, and then follow with another brush charged with pollen taken from free-setting varieties, operating about midday. The bunches also require drawing out—that is, affording a higher temperature. With this, 65° to 70° at night, and 10° to 15° more in the daytime, there should be no difficulty, as the ovaries and ovules are perfect. Perhaps a little more phosphoric acid would be of service, with some magnesia and iron. We should try the effect of a mixture of the following:—Dissolved bones, dry and crumbling, five parts; double sulphate of potash and magnesia, four parts; and sulphate of iron, finely powdered, one part, mixed, using 4 ozs. per square yard, and washing in moderately, the border previously being brought into a proper state of moisture. If the roots are very near the surface supply the dressing at twice, allowing a fortnight or three weeks between.

Woodlice in Vineries (Idem).—Woodlice will certainly eat the roots of Vines, and almost anything tender and good. We do not know of anything better than the two boards trap—two pieces of old board of the same length laid one upon the other where the woodlice haunt, sprinkling on the lower board a little fine bran or pollard, and covering with the other board, so as to allow the woodlice to get between, a small pebble being used when necessary. Examined in the morning the woodlice will be found secreted, and can soon be disposed of by brushing into boiling water. Another good trap is Mangold Wurtzel or Swede cut in two halves transversely, hollowed, notched round the sides so as to allow the woodlice to enter, placing that part where the pests congregate (fig. 75). I seen to every morning the vermin will be found secreted in the hollow, and can be brushed out into hot water.

FIG. 75.—TRAPPING WOODLICE.

A, wood-louse (*Oniscus asellus*), full size; B, pill-millipede (*Armadillo vulgaris*), rolled up as a ball; D, upper half of Mangold.

Propagating Jacaranda mimosifolia (Blandford).—This species is increased by cuttings of half-ripened shoots taken during the early summer months and inserted in sand over sandy peat. The cutting pots should be placed in heat, such as that of a propagating frame in a warm house, and kept shaded until well rooted, then gradually inured to the air of the structure. Sometimes the cuttings are inserted singly in small (thumb) pots, which is perhaps the best mode. The cuttings must not be over-watered, nor be more than half-ripened when inserted. The plant thrives in a compost of sandy peat and fibrous loam, with ample drainage. It requires a stove temperature.

Ivy-leaved Pelargonium Leaves Dying (W. W.).—The leaves are attacked by a minute species of animal parasite called the "rusted leaf" pest, *Tarsonymus gerani*. The best thing we have used against it has been nicotine essence, one fluid ounce in five pints of hot rain water, applying when cool enough to the under side of the leaves by means of an atomiser or pneumatic sprayer in the finest possible film, repeating occasionally. We have also found the vaporisation with nicotine essence, or fumigation with tobacco, at short intervals, to be effective. Tobacco water may be used instead of the nicotine essence. One ounce of strong shag tobacco should be placed in a vessel and three pints of boiling water poured on it, covered up closely, and left till cool, then strained and applied with a sprayer or syringe.

Diseased Cucumber (C. W.).—The portion of fruit is badly infested by the scale fungus, *Glæosporium Lindemuthianum*, syn. *Colletotrichum lagenarium*. The effect on the fruit is to spoil its appearance; it is shrunk and out of shape, and the seeds, if any are saved from such fruit, are generally shrivelled, and give rise to the disease anew. The disease is a very old one, and most prevalent during periods of wet and cold weather, the atmosphere of the structures being then also relatively close and moist, if not cold. As regards preventive measures, for remedy is out of the question, we have found the use of a little air-slaked chalk lime, a handful per square yard, and a similar quantity of soot, to have a good effect on the plants. Do not give more water than to keep the foliage from flagging, using a little flowers of sulphur on the hot-water pipes, and maintain a night temperature of 65°, with 70° to 75° by day, rising to 85° or 90° with sun, to encourage the plants growing out of the disease. The atmospheric moisture also requires moderating, and ventilation should be closely attended to, the object being to destroy the spores of the fungus or prevent their germination, as they can only grow in a close and comparatively moist atmosphere. The temperature should be relative to the vigour of the plant—that is, the more vigorous the more heat it requires to elaborate its juices and promote a healthy, disease-resisting growth.

Gypsophilas (Scotland).—There are several hardy herbaceous perennial species—namely, *G. cerastioides*, *G. fastigiata*, *G. glauca*, *G. paniculata* (a very elegant, light and graceful species), *G. perfoliata*, *G. repens*, and *G. Steveni*.

The Okra or Gumbo (N. B.).—We have no experience of this in this country, but in the United States it is started in pots in the northern parts. We do not consider it likely to succeed in Scotland outdoors, or do well in the south of England, even when forwarded in a hotbed, and afterwards planted out in a warm sheltered situation.

Is Ice Plant Edible? (O. F.).—We are not aware that this plant, grown chiefly for garnishing fruit, is edible. According to chemists the watery fluid of the ice consists of chloride of sodium (common salt), potash, magnesia, and sulphuric acid, together with albumen, malic acid, &c. Probably the plant may be used as medicine, but hardly as a vegetable—at least, the taste is saline and somewhat nauseous. The leaves of the species *Mesembryanthemum edule* or Hottentot Fig are, however, eaten. Probably you mean New Zealand Spinach, which we have sometimes heard referred to as Ice Plant, from its creeping and succulent nature. It is edible.

Nægelia (Gesnera) cinnabarina Culture (Dorset).—This appears to be the plant with the "red velvety leaf," an exceedingly ornamental plant, both on account of the flowers, scarlet with a white throat, and because of the beautifully marked leaves. Flowering in winter renders it very desirable. The scaly tubers should be potted in May, or not later than June for flowering at Christmas, in a compost of peat, leaf soil, and a small quantity of loam, pressing moderately. Pots of about 6 inches in diameter are large enough for three tubers, covering with an inch of soil, or a large one in a 5-inch pot. Water carefully, but keep the soil moist until the plants are growing freely, then supply water copiously. Do not syringe the plants, as sediment spoils the foliage. As the foliage dies down let the soil gradually become dry, in which keep the tubers until you start them again.

Growing Cucumbers and Melons in the Same House (W.).—It is rather difficult to grow the two together, but often done satisfactorily, the Cucumbers occupying the northern and the Melons the southern side of the structure. When the Melons are setting their fruit or coming into flower, the syringing on the other side of the house can be moderated, whilst the fertilisation has been effected; indeed, there need be little difference, only take care not to produce a saturated and stagnant atmosphere. Instead of that, a little air should be admitted constantly, so as to prevent the deposition of moisture on the flowers, then by carefully syringing on the other side, or even damping only, a good set may be secured, a little extra warmth being given to allow of the constant ventilation. When the fruits are ripening nothing need be feared, only do not stint the Melons for water during the swelling period, or, on the other hand, give an excess. If you proceed the same at the maturing period as the setting time the Melons ought to finish well. It only requires a little care, and then both can be had from the same structure. Such, at least, is our experience, necessity having prompted the overcoming of difficulties, if such can so be called.

Mushroom Spawn (E. A. T.).—You are not advised to use the spawn from the old bed, either directly in a new one or for the purpose of making spawn bricks. It is not much easier for a person to make these from instructions on paper alone than it would be in the same way to teach how to make a watch. You will find somewhere in "Mushrooms for the Million" something to the effect that it would be as advisable and practicable for any builder to make his own bricks as for every grower of Mushrooms to make his bricks of spawn. The attempt would be ruinous, as not one person in a hundred would succeed in the absence of "object lessons." Spawn that is formed in a bed that has produced a good crop of fine Mushrooms is always weaker than that which was used in producing them, as it degenerates by every generation of transmission, so to say, from crop to crop; that is why professional makers of the familiar bricks will give very high prices for virgin spawn, or that direct from the spores of Mushrooms, for producing very strong "bricks"—not for sale, but for reproducing others of the first quality for that purpose. The greater the number of removes from the spores the weaker the spawn, mycelium, or Mushroom plant is said to become. The most successful growers of Mushrooms in the kingdom, whether on a large or small scale, with few exceptions, purchase (not make) the spawn bricks they use. As the kind you used last appear to have been so satisfactory, the best thing you can do is to purchase more of the same kind, from the same source. We, however, answer your questions. The "cakes" should be dried steadily, three walnut-sized lumps of spawn from strong bricks inserted in each at the right time, and the "cakes" so stacked on edge that when covered with fermenting material the warmth (about 60°) will circulate through on both sides of each, and when they are permeated with fine silvery fibres the covering must be gradually removed and the bricks dried.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably

injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*R. I.*)—1, *Daphne Mezereum*; 2, *Scilla sibirica*; 3, *Anemone Hepatica*; 4, *Billbergia nutans*; 5, *Begonia sulcata*; 6, *Acalypha Mæfeana*. We are always glad to assist readers, so do not hesitate to write when you require information. (*D. W. L.*)—The flowers sent are both good varieties of *Clivia (Imantophyllum) miniata*. (*F. M.*)—1, *Odontoglossum Andersonianum*; 2, *Cypripedium Exul*, poor form; 3, *Dendrobium Lowianum*. (*O. B.*)—*Angræcum sesquipedale*.

THE MANGOLD WURTZEL.

Now that every human being who has a shilling in his pocket and wants a dinner can, in any large town at least, pick and choose to his fancy's if not to his stomach's content, we may as well inquire whether we always study the tastes of our animals as well as we do our own.

Objection may be made, and no doubt with some reason, that animals as well as men do not always know what is best for them; but the palate is a fairly safe guide, and food that is attractive to the taste, if taken in moderation, will be generally beneficial to the system, human or otherwise. We may therefore accept as a general rule or axiom that the foods which farm animals prefer, if allowed in moderation—i.e., in fixed and regular rations, with proper change and variety—will prove to be the most productive of good health and rapid progress to maturity, and therefore the most lucrative to the farmer.

Yet there are farmers, and plenty of them, who will insist on their flocks and herds eating woody and woolly Swedes and Turnips, woody Swedes of the green-top varieties, because, forsooth, they are less liable to frost when left out unstored through a severe winter; and woolly common Turnips, either half-rotted by frost or half run to seed by mild weather, when, if they so chose, the animals might be enjoying and thriving on good yellow-fleshed Swedes or sweet and luscious Mangolds from the pies.

It is really wonderful to travel round some districts and see scarcely one pie of either Swedes or Mangolds; a large number of farmers never attempt to grow the latter, they would as soon begin to grow Cabbage, which they would consider akin to market gardening, and therefore infinitely beneath them.

When we remember that piod Mangold may be used for any kind of stock from January 1st to September 30th, or for a period of nine months; that Mangold is the best food for the ewes during the lambing season; useful for all kinds of cattle, but invaluable for dairy cows; an excellent addition to the winter food of horses; by far the best food to give with corn to store pigs during summer; and, if not consumed by the beginning of July, greedily eaten by lambs recently weaned, we can only marvel at the obstinacy of those who persistently refuse to grow it.

We have increased our acreage of Mangold, and tried to grow more than we could consume, but have never arrived at the latter point yet. We have after a fine Turnip season had the whole of our Mangold left in hand at Lady Day, but the pigs and the lambs were always equal to the occasion, and we have never yet known any to be wasted.

Seeing, then, that this is such a useful crop, it is surely worthy of a little extra effort and expense to produce. We are wrong in speaking of extra effort, there is none needed if the land has been treated as it should have been in autumn and winter.

All that is required, apart from thorough manuring, is a clean good tilth. The land having been fairly cleaned in autumn, and had its proper ploughing in early winter and early spring, should be ready for a Mangold crop as soon as it is wanted. Of course, if the land be foul and the ploughing has been scamped, there will be the usual plea that it is not suitable for Mangold, and the farmer will have another few weeks wherein to get it ready, or perhaps half ready for Swedes or Turnips. He will get what he considers a satisfactory crop of one or other of these, but one that is not worth half a good crop of Mangold.

All soils, except very bad blowing sand and very thin chalk, will grow Mangold, but those it most delights in are deep loams and peats. Strong soils grow it well, but require more care and foresight in the preparation.

In dry springs it is advisable to soak the seeds for twenty-four hours before drilling, but as there has recently been ample rain, there will hardly be any necessity for doing so this year. From 5 to 7 lbs. of seed are required for an acre, according to the nature of the tilth and the prospects of germination.

Ten to fifteen loads per acre of decayed manure make a sound foundation of food for the plants, though Mangold may be grown on good soil without muck at all. The manure must be well-decayed, not dry and strawy. The latter sort will do more harm than good, and rather than use it you had better use none.

With good muck we should not advise more than 3 or 4 cwt. of superphosphate per acre, but without muck 6 or 7. In any case 1 cwt. per acre of nitrate of soda or sulphate of ammonia should be applied at sowing time with or at the same time as the phosphate.

If no muck be used we should recommend 2 cwt. of sulphate of ammonia at drilling time.

But supposing we have got our Mangold drilled and rolled down to keep in the moisture, as soon as the young plants can be seen in rows they must be side hoed, for they grow rather slowly at first if the nights be frosty, and weeds, being hardier, are apt to partly smother and rob them.

Apart from the clearing and thinning, which require no description, there is little more needed except the top-dressing. Some farmers use 2 cwt. of nitrate of soda after the plants have been thinned, but it has been found that greater advantage is derived from dividing the dressing in two, giving 1 cwt. immediately after striking out, and the other three weeks later. We have used sulphate of ammonia for the same purpose, and put it all on at once—i.e., at the earlier period, and we have never had reason to be dissatisfied with the results.

WORK ON THE HOME FARM.

The heavy rains have done immense good, both to Wheat and early sown Barley, and all that we want now for a week or two is sunshine, and as we write the whole country is bathed in it, so let us hope that it is the forerunner of a fine season.

If old saws are worth anything we are in for a warm dry season, for the wind was persistently in the west on quarter day, and thousands believe in the quarter day forecast, and observe it accordingly. Although no believers in superstition, we are ourselves not without some faith in it.

Wheats are almost too thick, and must be thinned by harrowing. Barleys can be Cambridge rolled where they are big enough, and the Clover seeds, if yet unsown, may be sown on the roller seams. A flat roll taken over the land will then cover all in and save a harrowing, which, however carefully and lightly done, has a tendency to check the Barley, and cause an unevenness of growth and consequent loss of quality.

The severe frost caused quite a rise in the Potato market, and a very pleasant one to those who had any stocks left. The rise in price of 20s. per ton had the effect of increasing the area planted, several farmers who had been wavering as to the quantity they would put in having decided on the larger one. This has had an effect on the seed trade, tubers for planting having risen proportionately with the table Potatoes. It is still seasonable for planting, but April we think quite late enough.

Autumn planted Cabbages should now be making good growth. If, however, they do not progress as they should, 100 to 200 lbs. per acre of nitrate of soda, sown at once, will soon make an alteration. Hares and rabbits are partial to young Cabbage plants; where they are troublesome a good dressing of soot (a ton on 3 acres) sown on a showery day, when the soot will stick to the leaves, will not only keep the little pests off, but snails as well, besides acting as a not to be despised manure for the crop.

REMARKS.

- 9th.—Brilliant morning; cloudy from noon; steady rain from 3.30 to 7 P.M., and showery after.
 10th.—Steady rain till 5 A.M., and showery till 10 A.M.; occasional gleams of sun later; heavy rain 4 to 4.30 P.M.; bright night.
 11th.—Overcast and rainy early; sunny from 10 A.M., but occasional flakes of wet snow.
 12th.—Bright sun all morning, a little hazy after noon.
 13th.—Drizzly and rainy from early morning to 11 A.M.; fair day with some sunshine; rain again at night.
 14th.—Incessant rain till 11.15 A.M., fair after; rain at night.
 15th.—Rainy till 4 A.M.; pleasant day, with some sunshine.
 A rainy and variable week, with little bright sunshine. Temperature near the average.—G. J. SYMONS.

VISITORS INVITED

To see the Grand Display of

DAFFODILS

NOW IN BLOOM

AT

Barr's Nurseries

LONG DITTON, SURREY.

BARR'S NURSERIES are reached from London by the L. & S.W. Ry. to Surbiton Station, and from thence a short walk past the New Recreation Grounds, or cab to Pound Farm Entrance (cab fare, 1/-).

Visitors invited to see the DAFFODILS in flower, April; TULIPS in flower, May; other HARDY FLOWERS, "The Year Round."

A CONSTANT DISPLAY OF DAFFODILS

Is also maintained during April at

12 & 13 KING ST., COVENT GARDEN, LONDON

VISITORS INVITED.

GERBERA JAMESONI

This beautiful African Daisy, bloom deep orange, 3 to 4 inches across. Fine healthy plants in 5-inch pots. Price in flower or bud 3/6, others 2/6 each.

HEDLEY H. COOMBS, North St., Wilton, near Salisbury.

BEGONIAS for 1899.

B. R. Davis's New Catalogue will be sent to all purchasers of this popular flower. A correct Descriptive List, with revised prices, of one of the largest and best collections in existence. Also

B. R. DAVIS'S NEW GARDEN ANNUAL.

For purchasers of first class, reliable Garden Seeds and Plants.

B. R. DAVIS,
YEOVIL NURSERIES, YEOVIL, SOMERSET.

READY.

H. J. JONES'

CHRYSANTHEMUM GUIDE (110th Thousand)

This valuable work is now ready, and will be sent post free for Seven stamps, or bound in cloth, 1/2. It contains an article on Stopping and Timing nearly 700 Varieties; several experts have written saying that this alone is worth double the money, and should really prove invaluable to all Growers.

For CATALOGUE of

Best Chrysanthemums, Best Fuchsias,
Best Begonias, Best Gloxinias,
Best Caladiums, Best Heliotropes,
Best Carnations, AND
Best Dahlias, Best Pelargoniums,

SEND TO

H. J. JONES, RYECROFT NURSERY, LEWISHAM.

No. 183.—VOL. XXXVIII., THIRD SERIES.

CARNATIONS.

TREE OR PERPETUAL-BLOOMING VARIETIES.

THE FINEST WINTER BLOOMERS EVER INTRODUCED.

EXMOUTH GEM.—Lovely and delicate pale salmon flesh colour. Blooms of large size and fine form. Free flowering and robust grower. There is nothing to equal this in Carnations, and the colour is one always in demand. 3/6 each.

MRS. HERBERT STEWART.—Magnificent bloom, sometimes 3½ inches in diameter, of fine form; rich carmine-rose colour. 2.-.

LADY DOREEN LONG.—A decided gain in yellow grounds. Certainly the largest and freest flowering in this section; a great acquisition. 2.-.

LADY GERTRUDE ROLLE.—Colour, size, and form similar to the popular border variety, DUCHESSE OF FIFE, but the rose-pink colour is clearer and richer. The best of habits and free-flowering. 2/-.

NELLIE STEVENS.—Pale flesh, in size and form quite equal to the Show or best border varieties; strongly perfumed. 3/6.

PEARL BEAUTY.—A large white, of rare substance; freely produced and strongly perfumed. 2/-.

No one who requires REAL GOOD CARNATIONS for any purpose all the Year Round, should hesitate to order these magnificent varieties.

Strong Plants, in large 60's, Now Ready.

W. J. GODFREY
EXMOUTH, DEVON.

CARNATIONS.—BORDER CARNATIONS, in 20 fine named varieties 5/- per doz., 35/- per 100, carriage paid and package free for cash with order Catalogue (150 pages) free.

JOHN FORBES, Nurseryman, Hawick, Scotland.

ASPARAGUS.—This delicious vegetable does not require half the expense usually incurred. For simple instructions see SEED LIST, free on application. Strong roots from 2/6 per 100.—RICHARD SMITH & CO., Nurserymen and Seed Merchants, Worcester.

HOLLYHOCKS. For the best collection of finest named HOLLYHOCKS extant, see Forbes' catalogue (150 pages) free on application.—JOHN FORBES, Nurseryman, Hawick, Scotland.

FOWLER'S LAWN SAND.—This preparation is for destroying Daisies and other weeds on lawns, and at the same time stimulating the growth of the grass. If one tin is tried as a sample its value will be at once appreciated. Sales are largely increasing. Tins, 1/-, 2/6, and 5/- each; Kegs, ¼ cwt. 8/6, ½ cwt. 16/-, 1 cwt. 30/-.

CORRY & CO., Ltd., Finsbury Street, London.

PURE WOOD CHARCOAL, Specially Prepared for Horticultural use. Extract from the *Journal of Horticulture*: "Charcoal is invaluable as a manurial agent; each little piece is a pantry full of the good things of this life. There is no cultivated plant which is not benefited by having Charcoal applied to the soil in which it is rooted." Apply for Pamphlet and Prices to the Manufacturers—

HIRST, BROOKE & HIRST, Ltd., Leeds.

GREENHOUSES from £3 5/-; **VINERIES,** CONSERVATORIES, FRAMES, SUMMER HOUSES, &c. Illustrated List Free. Makers to H.M. THE QUEEN and H.R.H. THE PRINCE OF WALES.

THE MAGIC OF SPRING.

THE following lines by Mr. Stopford A. Broke are timely:—

A little sun, a little rain,
A soft wind blowing from the west—
And woods and fields are sweet again,
And warmth within the mountain's breast.
So simple is the earth we tread,
So quick with love and life her frame,
Ten thousand years have dawned and fled,
And still her magic is the same.
"Westminster Gazette."

How certain, amidst all its uncertainties, is spring to come. Its progress may be checked by gusty storms of hail or sleet, by nipping frost or biting eastern gales, but the gentle spirit of spring, borne on the soft west wind, at last prevails, and ushers Flora to her fair domain. What a glorious thing is youth, with all its possibilities! And whether it is the first flush of vegetation in the spring, or the dawning consciousness of power in the young, it is fraught with a fascination found in no other period of life. The pleasures of anticipation are its prerogative; "Hope springs eternal in the human breast." Such pleasures, alas! as are seldom equalled by ultimate attainment, or rarely revealed in the realisation of fondest hopes. Herein is the magic of spring—the magic of life.

Who has not felt that witchery which worded the yearning, "Oh, to be in England now that April's there?" And who, as gardeners, do not view capricious April and "the delicate-footed May" with an anxiety ever oscillating 'twixt hope and fear, till showery June's dark south-west gale has blotted out another spring, and it is numbered with the thousands that have fled? A few inches more or less of rain; a few degrees of rising or falling temperature! The veriest trifles are these in Nature's deep design; yet how much they mean to those who woo her favours, and not rarely receive a rebuff. Certain it is that the beneficent mother is not apt to spoil her gardening sons by over-indulgence. It is the higher training of her servants and ministers, who, once slaves, may, in the fulness of time, become her masters. Let us, therefore, not only "hope" but strive for the mastery.

At this season Nature seems at once our friend and our foe, so often does winter take leave, yet seem reluctant to depart. The old magician smilingly waves her wand over the bare branches, and fruit trees are transformed into bridal wreaths for the marriage of Nature by her winged messengers of love. When she begins with so much pomp and show why is the end so little and so low? This in allusion to an average season, when winter and spring seem, somehow, so hopelessly mixed. Is it something beyond our ken or help? Not wholly so, perhaps. Note an aged Apple tree, or an old Pear tree in all its present picturesque beauty. There are thousands of such trees, beautiful for a time, yet subsequently fruitless, to point the moral of devitalisation. It is much the same in fruit results with the young and vigorous—in habit gross, in nature plethoric—while blossoms on other trees, firm, matured, and constitutionally sound, may come unscathed through the passing frost—a lesson in nature not to be overlooked; but on the contrary, recognised and turned to account as best we may in our methods of cultivation.

"So simple is the earth we tread." But how marvellous in its fecundity! Nature is a merchant who works up every shred and ort and end into new creations. So said that great metaphorical moralist, Emerson. Since that stupendous third day of Creation, whose morning saw the first faint trace of the lowly Lichen's life, and the evening closed upon gigantic plants whose skeletons are enshrined in our coal beds; down through the countless ages to our own little span, has the sublime work been carried on. "Dust to dust," the record of the centuries, still affords material for the great rebuilding—great ruins making way for greater glories, animal or vegetable, either, both, each dependent on the other. Though spring effects, as seen in the mighty regeneration imply subsequent exhaustion, this is only the precursor of continued life and deterioration not apparent on our planet.

"Quick with life and love her frame" undoubtedly is. Changes there must be, here and there, in spots on the surface, but over the great circumference as a whole there is no exhaustion yet, and should it ever occur who knows what great revivifying force may be yielded by the wondrous atmosphere so rich in the elements of food production and earth rejuvenation? Sufficient for the day, however, are the fertilisers to hand, and there is no greater advance shown in the history of our ministrations to the vegetable kingdom than that of concentrated foods for the nutriment of its subjects. The well-fed plant is like the well-fed animal, in being better able to withstand the vicissitudes of our climate. It is an old story, *à propos* of this, of the ducal employer who predicted to his gardener that good time coming when one waistcoat pocket would hold sufficient to fertilise the garden; with the reply that the fellow pocket would then, probably, hold the produce. In its broader sense the time has not arrived, and possibly never will, when, without under-rating these refined aids to fertility, bulk, as represented in the ancient form of restoration, will be regarded as of no account. Where chemical manures have been wholly employed for some years (an instance is under notice), Nature seems a little inclined to resent this homœopathic dosing.

Truly we live in an age of progress. So much has been done, is being done, and will be done; yet how often when some more daring attempts are made to force the hand of Nature is the banner of *Festina lente* displayed from her strongholds. Yes, in the headlong rush of life it may be well to pause at times and "hasten slowly," for sleepy diseases, rusts, blights, and all the bugbears of up-to-date gardening, bear witness to an inherent retributive power it is unwise to ignore. That there is nothing new at present under the sun is a truism; but modern methods have provided new hosts for these parasitic pests with endless trouble in combating them. Other illustrations are not wanting which enforce the wisdom of conforming to natural laws—to prompt a larger and a livelier faith in Nature, with whom—

"Ten thousand years have dawned and fled,
And still her magic is the same."

—AN OLD STUDENT.

ORCHARD FERTILISING IN NOVA SCOTIA.

(BY MR. CECIL H. HOOPER, OF SWANLEY, KENT.)

Farmyard Manure.—This is found very beneficial to old neglected orchards requiring nitrogen, but where trees run too much to wood and leaf with but little fruit, it is found better not to use it. Ten tons of farmyard manure add roughly about 120 lbs. nitrogen, 120 lbs. potash, and 60 lbs. phosphoric acid. It is considered that as a manure for Apples, potash should be given in addition to farmyard manure.

Wood Ashes are applied in Canada to orchard land at the rate of 20 to 40 bushels per acre, being perhaps the best possible manure; hard wood ashes are more valuable than from Fir trees. They contain, when not washed by rain, about 5 to 7 per cent. potash, and 2 per cent. phosphoric acid.

Bonemeal and Muriate or Chloride of Potash.—As the supply of farmyard manure and wood ashes is very limited, commercial fertilisers are largely used. In the Apple orchards of Nova Scotia the two kinds in most common use are finely ground bonemeal at the rate of 5 to 8 cwt. per acre, containing nitrogen 2 to 3½ per cent., and phosphoric acid 22 to 23 per cent., with muriate of potash 1 to 3 cwt. per acre, containing about 50 per cent. potash. These are mixed together, sown broadcast, and ploughed in early in spring.

Nitrate of Soda.—This is sometimes used to renew the vigour of old Apple trees and to young ones that are not making satisfactory growth, using about 1 cwt. per acre. It is also used to a considerable extent for Strawberries in the U.S.A.

A Mixture for Small Fruits.—The "Farmers' Advocate" recommended for small fruit (Strawberries, Raspberries) in Nova Scotia, 100 lbs. of nitrate of soda (= 15 lbs. nitrogen); 200 lbs. of muriate of potash (= 100 lbs. potash); and 550 lbs. bonemeal (= 16 lbs. nitrogen, and = 126 lbs. phosphoric acid).

A Mixture for Orchards.—Professor Frank J. Shutt, M.A., chief chemist Dominion Experimental Farms, in January, 1899, at the Nova Scotia Fruit Growers' Association meeting, recommended as a fertiliser for Apple orchards:—100 lbs. of bonemeal (= 3 lbs. nitrogen, and 22 lbs. phosphoric acid), 100 lbs. of superphosphate (= 15 to 20 lbs. phosphoric acid), and 75 lbs. muriate of potash (= 37 lbs. potash). If kainit (13 per cent. potash) were used instead of muriate of potash (50 per cent. potash), the equivalent would be nearly 300 lbs. of kainit.

Composition of Leaf and Fruit of Apple.—Although the application of fertilisers is not entirely based on the composition of the plant, but is more governed by the nature and capacity of the plant to take up food, and by the constituents of plant food most likely to be needed by the soil; yet it is of interest, and to some extent a guide, to know the composition of a plant. Professor Shutt calculated that the foliage on an acre of Apple trees, assuming forty trees, with 50 lbs. of leaves per tree = 2000 lbs., their composition when mature, but still green, would be approximately—nitrogen, 17.74 lbs.; phosphoric acid, 3.38 lbs.; potash, 7.84 lbs.

In the fruit from trees twenty-five years old, yielding 160 barrels of 140 lbs. = 22,400 lbs. or 10 tons per acre, the chief elements of fertility taken from the soil would be—nitrogen, 8.9 lbs.; phosphoric acid, 5.3 lbs.; potash, 32.8 lbs. The leaves are returned to the soil, but the fruit is exported.

A useful formula recommended for manuring orchards is:—Good rotten yard manure, 10 to 15 tons per acre; kainit (13 per cent. potash), 300 to 700 lbs., or muriate of potash (50 per cent. potash), 100 to 200 lbs.; bonemeal (finely ground), 100 to 200 lbs., or superphosphate, 125 to 250 lbs. It is recognised that rotation in manuring is of advantage.

E. B. Voorhes, of the New Jersey Experiment Station, recommends, in order to provide vegetable matter and to insure a sufficiency of lime as plant food, apply lime at the rate of 25 bushels per acre once in five years. To provide in addition an abundance of all forms of available plant food at the times needed for the development of the tree and fruit, apply annually chemical fertilisers in the following proportions:—Nitrate of soda, 100 lbs.; South Carolina rock superphosphate, 100 lbs.; ground bone, 200 lbs.; muriate of potash, 200 lbs. He adds the amount to be applied depends upon the character of the soil and the kind of fruit, and the age and vigour of the tree; those given mark the minimum. In a number of the best orchards the quantities applied are very much larger than is here indicated, and the larger application is believed by the growers to be proportionately profitable.

Strawberry and Small Fruit Manure.—The Bowker Fertiliser Company, a large and reliable firm of Boston and New York, and from whom the Nova Scotian farmers buy large quantities of fertilisers, make its Strawberry and small fruit manure with the following analysis:—Ammonia, 3 per cent.; available phosphoric acid, 10 per cent.; total phosphoric acid, 12 per cent.; potash, K₂O, from sulphate, 4 per cent. This fertiliser has for twenty-five years produced most satisfactory results, containing a large percentage of potash and

phosphoric acid for the production of fruit, with sufficient ammonia to produce healthy foliage and abundant berries.

Fruit Tree Manure.—The manure of this company has the following analysis:—Ammonia, 3 per cent.; available phosphoric acid, 6 per cent.; total phosphoric acid, 10 per cent.; potash, K_2O , 10 per cent. Apply 1000 to 1500 lbs. per acre, depending upon the condition of the land, previous manuring, cropping, &c.

Green Manuring.—Growing crops to plough in, such as the various Clovers, *Trifolium incarnatum*, Vetches, Peas, and Buckwheat, are much employed for enriching the land. The orchard land is kept frequently harrowed during summer to keep a fine tilth of about 3 inches during the period of active growth. The above "cover" crops are sown soon after midsummer and ploughed in early in spring, so as to retain the moisture accumulated during the winter, and to allow the trees to make an early start. Vegetable matter is thus added, and in the case of leguminous crops nitrogen is added to the soil at the smallest possible cost.

For orchards with Clover the "Farmer's Advocate" recommended 200 lbs. of muriate of potash and 250 lbs. Thomas' phosphate (basic slag), 16 per cent. phosphoric acid.

For further information as to fertilising orchards in the United States, the principles of which are applicable the world over, I would recommend perusing a book by Prof. L. H. Bailey of Cornell University, "The Principles of Fruit Growing," price 5s., published by Macmillan and Co., Ltd., London and New York, who are advertisers in your columns.

SPRAYING FRUIT TREES.

I AM much obliged to your correspondent Mr. C. H. Hooper for his courteous reply to my questions on page 272, April 6th inst., re $\frac{1}{3}$ to 1 lb. caustic potash to 1 gallon of water. I am careful not to use more than 1 lb. of caustic soda and 1 lb. of pearlash to 10 gallons of water. After Mr. Hooper's great experience one need not fear making the solution a little stronger for trees in a very bad state. We may be sure that the young growth of the previous year will not suffer from the application.

In looking over some fruit trees during the last few days I find my old enemy American blight appearing in the rough edges of the wounded and cankered parts of the trees, where the last spraying did not reach them. The trees most affected are King of the Pippins and Hawthornden. I shall try to give these parts another dressing this week with a solution of 1 lb. caustic soda, with 1 lb. of pearlash, to 5 gallons of water. As this pest is just now growing a fine crop of white whiskers, I trust my treatment will stop their further development. Hitherto I have painted the parts so affected with a mixture of softsoap and soot worked to the consistency of cream, and applied with an ordinary paint brush. At some future time I will beg leave to give your readers the results of this caustic solution treatment. —JNO. MILES.

ODONTOGLOSSUM CRISPUM ASHWORTHIANUM.

CONSPICUOUS, even in such a superb display as that at the Drill Hall on Tuesday the 18th inst., was *Odontoglossum crispum Ashworthianum* (fig. 76), which was exhibited by Mr. H. Holbrook, gardener to E. Ashworth, Esq., Harefield Hall, Wilmslow. The Orchid Committee of the Royal Horticultural Society recommended a first-class certificate. Orchid lovers will recognise it as of similar type to *O. c. Baroness Schröder*, which has been illustrated in our pages. In form and colour the flower is exceptionally beautiful, and the delight of visitors who noticed it cannot be a matter for surprise. Almost the whole surface of the upper sepal and petals is dull crimson purple with white fimbriated margins; the lower sepals and splendidly fringed lip are similar in colour, but have more white. It was most unfortunate that the immense number of exhibits compelled the authorities to relegate this and other handsome Orchids to a dark position behind the curtain, where it is probable many visitors would not see them.

NANODES MEDUSÆ.

THIS is a singular Orchid which is sometimes called *Epidendrum Medusæ*, and one that occasionally gives the cultivator much trouble. It makes no pseudo-bulbs, and therefore must have water all the year round, although the quantity should be less in the winter months. The plant does well suspended in a cool house quite close to the glass, and ought to be grown in a basket of clean live sphagnum moss. A plant of the above species when well flowered always commands attention, and the extraordinary flowers, which are of a deep maroon

purple with a greenish disc, with the whole margin cut into segments, forming a deep fringe, has a most singular appearance.

DENDROBIUM ROLFÆ ROSEUM.

A delightful *Dendrobium* named by Rolfe when it first flowered in the collection of the late Major-General Berkley, who was inclined to think it was a variety of *Dendrobium nobile*, which it much resembles, but the dark disc in the lip is entirely absent. The above variety, as its name implies, has sepals and petals of a beautiful bright rose colour, with flowers about as large as a good variety of *D. nobile*. It will succeed well with the last named species, which is supposed to be one

FIG. 76.—ODONTOGLOSSUM CRISPUM ASHWORTHIANUM.

of its parents, and *D. primulinum* the other. Whether it be a hybrid or not it is well worth adding to any collection of *Dendrobiums*.

ODONTOGLOSSUM WILCKEANUM.

This natural hybrid *Odontoglossum* has been proved to be a cross between *O. crispum* and *O. luteo-purpureum*, and often appears in importations of both species, and is perhaps more sought after by connoisseurs than any, on account of its beautiful flowers. There is great variation, as is to be expected from such parents, but all are extremely attractive, and to a lover of yellow flowers will be hard to beat. The spikes often carry from fifteen to twenty flowers, fully $3\frac{1}{2}$ inches across, of a pale yellow colour, with large blotches and often spots of light brown and chocolate on the sepals and petals, the latter much serrated at the edges; the lip, which is a little paler, has two distinct ragged keels. It will succeed under the same conditions as *O. crispum*, and flower in the spring months. Several of the most distinct varieties have had varietal names, and they are well represented in our best collections.

ONCIDIUM CUCULLATUM.

This small growing plant from New Grenada is not often seen in robust health, which is sometimes to be attributed to its being grown in too dry an atmosphere and in too high a temperature. This species and its varieties will succeed under the coolest treatment, and will well repay the cultivator for any pains he may bestow upon them. I find they succeed well suspended quite close to the glass in a house in which *Disa grandiflora* revels, potted in the usual Orchid compost, and during the summer months well supplied with water. The varieties differ considerably in colour, but all are beautiful, and the richly spotted deep violet lip in the best forms is generally very much admired. *Oncidium phalaenopsis* and *O. nubigenum* are supposed by many to be varieties of this species, but whether they are botanically or not, to the cultivator does not matter, as they will all succeed under the same treatment.—J. BARKER, *Hessle*.

LÆLIO-CATTLEYA GOLDEN GEM.

A correspondent has kindly sent me flowers of this pretty little hybrid, and asks for its parentage. The first time I saw it named as above was at the Temple Show, in one of the large trade groups, and alongside it was *Lælio-Cattleya intermedio-flava*, a hybrid between *Cattleya intermedia* and *Lælia flava*. The two are exactly alike in all respects, and, though I have no evidence on the point, I think it is very likely they were raised from the same pod of seed. The "fancy" name is prettier than the more correct appellation, though there are reasons why these should not be given.—H. R. R.

GRAPE GROWING OUTDOORS AND IN COOL HOUSES.

(Concluded from page 324.)

WHAT reason, then, but indifference for the non-production of Grape wine in England? In the year 1897 duty was paid on 15,853,071 gallons of wine imported into this country. Surely some part of this vast quantity could be produced in England. Would it pay? That is just the point the owners of land and the cultivators of the soil want to know. The answer can only come through experiments in different parts of the southern districts of England and Wales. Of quality there appears no question, for the Welsh wines of the nineteenth century, like the Duke of Norfolk's of the eighteenth, are "better than imported." The testimony from the Castle Coch and Swanbridge vineyards seem conclusive on that point, and that of paying or otherwise remains to be determined by experiment in different parts of the country.

The varieties grown for wine making are the Black Cluster, Miller's Burgundy, and Gammé Noir, all with small round (the first named has slightly oval) berries, blue-black when ripe, which usually occurs at the end of September or beginning of October. In the Castle Coch vineyard the Vines are placed 3 feet apart every way, and have stems about 1 foot in height, the growths being secured to upright stakes rising about 4 feet from the ground. The Vines are thus grown on the stool system, like Osiers, the shoots being shortened to a bud or two at the winter pruning, the growths from them thinned, leaving the most promising, and stopping them a few inches from the top of the stakes. I do not know what the produce of such Vines may average annually. Some I had that way gave 3 lbs. per stool, but the variety was Cambridge Botanic Garden. This produce means over 6 tons per acre at 3 feet distance apart, or equal to an average crop of field Potatoes. Will "Upwards and Onwards" kindly say how many gallons of English champagne such produce of Grapes would make?

The Grape Vine may yet again appear on the sunny slopes of southern England and be grown for producing fruit to eat or make into wine against the south walls of buildings in the southern and midland counties, for it thrives on gravelly, sandy, and calcareous soils, producing Grapes rich in flavour, the wine has a full body, and possesses a rich bouquet. It thrives on alluvial soils where water does not lodge in the sub-strata, but the Grapes are sharp in flavour, the wine harsh, but improves by keeping. The soils of the red sandstones, dolites, calcareous and ferruginous gravels, and river-drifts, high and dry, suit the Grape Vine. Most natural soils, especially the stony, grow good Grapes, and often are better than made up borders. If wet, drain them; if low, raise them; if heavy, lighten them by adding rough material, such as brick rubbish or burned clay; and if light, make them more compact by a judicious admixture of marly clay, dried and pounded. Provide in every case just such another staple as for growing any other tree, shrub, or plant, naturally addicted to growing in a generous, well-drained soil, and it will grow far more useful Grapes than the most expensive border ever made.

The Vine requires a high wall with a due south or south-east to south-west aspect. Now is, perhaps, the best time of the whole year to plant the Vine. It will cover a very large area of wall space, such as the whole end or front of a cottage, therefore arrange accordingly, planting the Vine in the most central position. As there will not be time to make any special provision for planting, simply add a liberal dressing of manure to soil such as described, and plant the Vine forthwith, then it will make several feet of growth this summer, and be a great ornament on an otherwise blank wall. A hole about 3 feet wide will mostly accommodate the roots of a one-year-old Vine. Stir the soil well to a depth of 18 inches or a couple of feet, mixing manure with it. If necessary to make a soil for planting in, take five parts of any ordinary soil, say the top ameliorated earth, one part each of lime rubbish, charred refuse, or wood ashes, and horse droppings, and a peck of fresh soot. Mix all together, and the "queen of fruits" will mark appreciation by doing well provided the drainage be sound.

The best varieties for walls are Black July, Black Prince, and Black Hamburgh; White, Chasselas Vibert, Royal Muscadine, and Early Smyrna Frontignan. If only one of each be wanted select the first named of the respective sections.

Greenhouses are common, almost every suburban and rural dwelling has one attached or near by. There is no climber equal to the Grape Vine. It does well with the roots outside, and in a proper soil gives no further trouble, or very little as regards watering. Of course it can be planted inside, but whether there or outside, the soil named answers equally well.

The varieties most suitable for a cool house, or one from which frost only is excluded, or without heat in warm localities, are:—Black: Black Prince, Black Hamburgh, and Madresfield Court. White: Chasselas Vibert, Early Smyrna Frontignan, and Foster's Seedling. The two best are Black Hamburgh and Foster's Seedling. One, or

at most two Vines, suffice for a small greenhouse, hence the reference to the best.

In planting outside, a hole or holes must be made in the wall or boarding of the house where the Vine or Vines are to be planted for taking the cane or canes into the structure. Then proceed to plant one-year Vines. Turn them out, disentangle the roots, and place in position in the soil, moderately firmed, at such height that, when covered with soil, they will be an inch deeper than they were in the pots. Spread the roots out in every direction, with a slight inclination downwards, and cover with soil, none deeper than 6 inches, and some 3 inches. Give just sufficient water to settle the soil about the roots, and then a surface dressing of horse droppings, or other short sweetened manure, to the thickness of a couple of inches. If the Vines have not been pruned, rub off the buds down to where principal growth is required to form the continuation of the stem, which for those planted outside a house must be within it; but for those against walls, start the main growth about a foot from the ground, and in either case, be content with one cane this year. Other matters will require attention from time to time, but they are referred to in "Work for the Week," or if not exactly what is wanted, write to the Editor.—G. ABBEY.

LONDON GARDENS OVER FIFTY YEARS.

No. 7.

BESIDES its near association with three royal palaces, one of which has vanished (that of Whitehall), the park of St. James's is linked to so many historic incidents and notable persons that it must ever stand pre-eminent among the London parks. Nor are there wanting facts which associate it with the horticulture of the past as well as the present. Our first description of the centre portion of the park presents us with a marshy scene, a rivulet running in from the Thames had little rills flowing irregularly right and left; it must have been a favourite resort of wild fowl, rich also in wild flowers.

Along the north side extended the higher ground of St. James's Fields. King Henry VIII. enclosed the greater part of the park, which was larger then, including Pall Mall certainly. He planted trees freely, we may assume, since the poet Milton mentions the shady groves of the park, which must have had time to grow. It was not till after the Restoration that Le Notre, deemed by many the greatest gardener of his century, assisted by Dr. Morison, laid out the ground methodically, constructing the lake and forming avenues. But of his work little remains except the Mall, extending from Buckingham Palace to Spring Garden Gate; probably there is scarcely a tree left of his planting. The general plan of the park, as we now see it, is the result of changes made during the reign of George IV.

But long before his time I believe all the Apple orchards had disappeared from the locality, though even yet there lingers the name of Apple Tree Court, St. James's. Various references occur to these orchards in old authors; very likely other fruit trees flourished along the slope of the hill. There may even have been a vineyard, as not many years since good Grapes were obtained from a wall at St. James's. The parish records have a curious allusion to a "phesic" garden. We cannot be certain where it was, but this may have been on the plot of ground near the tennis court, which Charles I. granted to Parkinson, herbalist and botanist. His principal garden, however, was situate in Long Acre.

Looking at Buckingham Palace we recall the Mulberry Garden of King James, which was on a part of the park now enclosed as a garden to the royal residence. It was one of the fancies of this monarch that silk might be produced here extensively, so he spent upwards of £900 on planting Mulberries, an amount for which he must have got a goodly number. But the silkworm scheme did not answer. Arlington House was built on a part of the ground, though the Mulberry Gardens continued to be a popular resort for some time; probably fruit was raised there. Perhaps descendants of King James's trees may yet be found in Buckingham Palace gardens.

Fifty years seems a good while in the retrospect, but St. James's Park of 1849 was not so very different from what it is now. Some old trees, mostly Elms, have gone, shrubs also that were familiar then replaced by a younger generation; others have advanced from shrubs to trees. Less conspicuous now are the numerous labels, which were presumed to convey botanical instruction to by-passers. They only told the name, Latin more frequently than English, with the natural order and country of the plants to which they were near. I would not say the plan was a bad one, perhaps it might be carried out to advantage now in our open spaces, indicating species and varieties about the beds or borders. In St. James's Park some of these labels were ludicrously shifted, through accident or for mischief, and, in a botanic garden somewhere north, many such used to be carried off from time to time by magpies. Unpromising, ragged shrubs have now been largely superseded by plants of a more ornamental character, and a few additional flower beds have been formed.

The grass of this park formerly had a very forlorn aspect, but

the lawns are no longer left to Nature, being resown whenever necessary, and kept well trimmed. Indeed, in all our important parks the grass is a pleasant feature of the scene, and receives the attention needful to its maintenance in a green and flourishing state. One of the modern improvements is planting, scattered or in groups, Crocuses, Snowdrops, Daffodils, and the like, among the grass on slopes, which make a show during spring. The lake exhibits the result of changes made about thirty years ago, when the bottom was concreted and the depth equalised; the margin also, which not unfrequently displayed mudbanks, has been altered for the better. In 1851, an observer called attention to the "hard line," which marred the beauty of this lake, as seen from various points, and remarked that it needed some diversity. Certainly there were a few uncouth Willows. I remember seeing a man carry one day kicking on the point of his penknife a fat caterpillar of the puss moth which had fallen off its food. However, we have now sundry semi-aquatic plants fringing the borders of the lake here and there, most of which are growing well. Formerly, the islands appropriated to the water-fowl were too crowded with vegetation, but a clearance has been made.

The Green Park, which once was called Upper St. James's Park, seems to have acquired its new name after the alterations carried out by Lord Duncannon about sixty years ago; probably before that date it was somewhat deficient in greenery. Beautiful views of distant Surrey are, however, no longer attainable from the higher ground. The shrubberies, situate along the east side of this park, were formerly regarded with admiration; to us there is nothing very charming about them. Some had venerable Thorns, Hollies, and Lilacs, which are now replaced by other shrubs; and the park itself contains many trees planted during the last twenty years. In the Green Park growth is often retarded by the cold winds of spring, and some young trees have been damaged by maddlesome juveniles. An unsightly reservoir, once prominent on the north side, has been removed; and as a border to Piccadilly we have a long row of beds, which are well filled during the summer with free-flowing plants. The flatness of this park has been remedied by forming dells and little hills.

Constitution Hill when I first knew it was open to the public right up to the wall of Buckingham Palace Gardens, but the footpath has been narrowed, part of the space railed in, and some flower beds made amongst the trees in the portion enclosed. Why was it called "Constitution," or as some say, *Constitutional Hill*? "To take a constitutional" is a phrase we cannot carry back far enough, for the road had this name in 1724, or earlier. Doubtless the stroll towards Hyde Park might be very beneficial, for many an invalid has gained strength by walking or riding, where refreshing breezes come from the northern heights. There was a time, indeed, when Hyde Park was bare and uninviting, but now it is a delightful spot in spring and summer, nor is it very dreary when winter rules the landscape.

Supposing we couple Kensington Gardens with Hyde Park, it will count as the largest of all London parks, or, leaving that out, Hyde Park stands second, being then surpassed by the Regent's Park. One thing we cannot forget about this park, that it was the seat of the Exhibition of 1851, pioneer of numerous later exhibitions throughout the civilised world, some of which have rendered great service to farmers and gardeners. My own recollections of the park do not take me back to the time when the double row of Walnuts extended from the north to the south side, near Park Lane, but I can remember when some of the very old trees remained that shadowed the famous Ring, and I think the deer had not been all removed then. Not far from the Humane Society's receiving house there may be found yet a few venerable trees, relics of the Stuart period; most of the finer park specimens are of last century only. Thousands were planted about sixty years ago in thick clumps, as the newspapers of the day complained. Nature remedied the crowding by killing off many, others were wantonly cut down. The Scotch Fir was freely put in to act as a nurse to others; unfortunately it seemed itself to want nursing in that locality, and did not flourish.

We are chiefly indebted to Mr. Gibson for having devised the alterations which have given the aspect of a garden to portions of Hyde Park. Fifty years ago the end of the Serpentine near Albert Gate was a muddy maledorous ditch, it has been converted into a pretty dell. April and May are the months in which the public throng to see the spring flowers, especially the Hyacinths; they are usually planted in oblong beds, one variety occupying each. Occasionally we have a bed arranged to show three colours, which make a pleasant variety. Tulips are also conspicuous, a large number being grown both of the early and late sorts. The Italian garden on the Bayswater edge of the Park is one of the best examples of this style.

Just a century ago, the records of the Board of Green Cloth inform us, compensation was given to the widow of a man shot by the keepers while they were hunting foxes in Kensington Gardens. At that date the gardens were much of the wood or warren, except on the Kensington side; probably there were rabbits about, and a poultry yard belonging to the Palace. Even in the reign of George III. part was kept as a garden, and people came long distances to see the

principal flower walk, extending 700 yards, which contains now many choice shrubs, and also a collection of bulbous, herbaceous, and bedding plants. Along the banks of the Serpentine are masses of Rhododendrons, with a variety of evergreen and deciduous shrubs, which have a capital effect. Then we have an attraction in the semicircular garden by the Cottage, which was planted in 1874, the design of Mr. N. Cole. During the spring the rows of trees crossing and re-crossing each other in the broad space are delightful to look upon.—J. R. S. C.

STOCKS FOR FRUIT TREES.

THE experience of the writer of the article under this heading on page 314, is so very different from my own that I feel compelled to say a word in reply. It would almost seem unnecessary at the end of the nineteenth century and after the subject has been written about for fifty years, to say anything more about the merits of the Paradise stock for Apples. One learns from experience, however, that teaching is still required, and if the rising generation read an article like this one in question, and see no reply thereto, they might conclude that all that has been previously written upon the merits of the Paradise stock was exploded, and that we had "changed all that" and gone back to working "at least 90 per cent. of the Apples worked in this country upon the wild Crab."

To commence with, I would reverse the figures named and say that probably not more than 10 per cent. of Apples now worked are upon the wild Crab, the balance being on seedling Apple and Paradise. Such a statement as this is naturally only a guess, but I think it will be found much nearer truth than the former one. For many years now we have worked 20,000 Apples a year upon the Paradise, and shall have to largely increase our production. Messrs. Rivers, Bunyard, Veitch, Dicksons, Cheal, and other growers too numerous to mention are growing equally large stocks; and how benighted we all must be if trees grown upon the Paradise are only fit "for fancy gardening."

The fact that we dispose of our trees and that the bulk of them go for market planting is a stronger argument than any other in favour of this stock, and will prove as convincing as a page of writing upon the subject. We have an order on hand for 5000 Apples on Paradise to go to a market grower this autumn, and we have sent them for market work in South Africa (by the way, we shall have to drop the title of "Dark Africa," and apply the "dark" to regions nearer home). If further proof were needed that market men were alive to the merits of Apples worked upon the Paradise I could refer your correspondent to dozens of growers who have planted them largely during the past twenty years, and only a short time ago one of our market friends told me he contemplated digging up 12 acres of Apples planted as bushes on the Free stock and replanting with trees on the Paradise. Why? because he had grown them side by side, and found those on Paradise paid him 50 per cent. more money. That I call practical.

But to pass on, your correspondent says "that it has never been satisfactorily proved that the stock of the Apple, Pear, or Plum exerts any influence whatever on either the quality or flavour of the fruit." This is to me a most amazing statement. I do not know anything of his soil or climate, but I would ask him, just by way of example, if he ever grew Cox's Orange on Crab and Paradise side by side, or Louise Bonne de Jersey on Pear and Quince? In this locality, and many others, one would scarcely know the fruits to be the same, and, speaking generally, when well cultivated the fruit of all kinds when grown on the Paradise is both larger and better coloured, added to which in many dessert varieties the flavour is distinctly superior. Cox's Orange is an example. Most of your readers who are fruit growers will be able to judge for themselves upon this point, but if they require any evidence, let them go to some of our fruit shows, and ask the exhibitors which stocks their exhibition fruit is grown upon. Almost in the same paragraph as the quotation given above one reads a recommendation to double graft Apples upon the Crab stock! But if the stock exerts no influence, what possible benefit can accrue from this operation? Has your correspondent tried it, or is it only "suggestion?" I presume it is the latter, as I know from experience that some of the weaker kinds will not grow when double worked upon strong-growing and prolific varieties. One double works Pears upon Quince, because some kinds refuse to grow upon the Quince direct; but I do not see any advantage to be gained by double working Apples, and, needless to say, the cost of the two would be much enhanced by this double operation and risk.

I do not intend to follow your correspondent through the other stocks he names, but I would point out that several of them are only useful for certain varieties of the fruits recommended to be grown upon them; for instance, not all Cherries will grow upon the Mahaleb, and I should like to ask him what varieties of Peaches and Apricots will succeed upon the Myrobalan? Some Plums will succeed upon it and make vigorous standards; but surely when one finds it much too vigorous for dwarf Plums, it would not be suitable for Peaches.—A. H. PEARSON, *Chilwell, Notts.*

PINCHING FRUIT TREES.

I AM firmly of opinion that pinching or stopping the shoots of fruit trees to form fruit buds is in certain cases a necessary evil. So long as fruit trees are trained in restricted forms, pinching, stopping, or shortening the current year's shoots when these would extend into vigorous long growths, will be necessary. The term "pinching" would appear to imply the early stopping of growths when yet young and soft, probably before the lower leaves have attained to full size. In such cases I would condemn pinching, and should say emphatically that the practice would not produce fruit buds the first season on Apples, Pears, and Plums. For pinching, stopping, and shortening generally to be productive of good results—i.e., the formation of fruit buds, it ought not to be practised on any growth before the principal lower leaves on such have attained full size. These pinched or stopped shoots must have abundance of light and air. The large leaves will then be able to perform their functions, which are of an important character. With the aid of the roots, which must be ramifying in fertile soil near the surface, the food from the earth is supplied to the leaves where it meets the food from the air. The whole is then manufactured or changed into material of a suitable character and transferred to the buds at the base.

It is similar with trees that do not grow in restricted form. If each shoot can have a fair share of light and air, and the roots are abundant and fibrous, extending in good soil near the surface, there will be an equality which will favour short jointed growth, and fruit buds will be largely encouraged.

I quite concur with the last sentence of Mr. Geo. Picker's note (page 317). I look upon pinching as supplementary to the various cultural stages in the management of fruit trees. Good soil, proper positions, young unspoiled trees, the best varieties, correct planting, are all more important than pinching, which depends largely upon those details as to its success or failure.—E. D. S.

FROM an experience extending longer than that quoted on page 317 by Mr. Picker, I quite agree with him that pinching the shoots of fruit trees does not induce the formation of fruit buds. I have tried the plan extensively on all sorts of trees, pinching in June, July, and again in September, and when the trees were winter pruned I failed to see that flower buds had increased in the slightest.

I know this experience is not in accord with the doctrine taught by some writers, but it is a fact, nevertheless, that there is far too much faith placed in the summer pinching of fruit trees to induce fruitfulness. The idea is broadly this—pinching off surplus growths to within a few inches of the base to check the flow of sap, induce the base buds to plump up, and thus form spurs for future fruit bearing. I am afraid this teaching is a long way from being practical.

It is difficult, indeed, to induce fruit buds to form from purely shoot buds. Fruit buds are formed naturally upon trees, according to various circumstances of variety, method of planting, as well as of training the branches. Some varieties of Apples, for instance, will form fruit buds too freely, so as to hinder the extension required for occupying surrounding space, while others will grow several years without the slightest sign of giving a fruit crop. This latter happens in spite of vigorous summer pinching of the shoots. If the pinching is effective, why is it that we see so many varieties of Apples fruitless year after year?

I am a strong advocate of summer pruning, or pinching, call it what you will, but it is not with the idea of inducing fruitfulness by the pinching only. I approve of the plan of cutting away all surplus shoots that are not required for the furnishing of the trees in their various forms of training for another object—viz., the admission of sun, air, and wind amongst the branches to mature them, and thus assist in naturally forming fruit buds.

If it were not for excluding light and air to the innermost parts of the trees, especially bushes, I would allow them to remain until September and then give the trees all the pruning they require. I do not believe in the practice of waiting until December to prune any fruit tree. Far better do it while the leaves are still hanging; it is easier to see what shoots are required, and the work is then more pleasant for the operator.

Even bush fruit trees—Gooseberries and Currants—I like to see summer pruned for the sake of having fruit clean and well coloured. Apples are undoubtedly better coloured where summer pruning is done to admit sunlight to the fruit. Some persons think that the latter has no effect upon the colouring of Apples; this opinion is not shared by—E. MOLYNEUX.

FOR the conditions of such a test as proposed by Mr. Picker to be perfectly fair all the trees must be on the same kind of stock, and as early fruiting is the aim, the Apples should be on the Broad-leaved Paradise, the Pears on the Quince. It will then be found that, generally, pinching done at the proper time, in the right way (there is an improper time and a wrong way) will induce free fruiting earlier than is possible in trees with unshortened growth.

As an exception I may mention a fine pyramidal Newton Wonder Apple some 12 feet high that in the sixth year from planting had only about six Apples, while a half-standard of the same sort planted at the same time near it had a heavy crop of fruit: both are on the Paradise stock.

But it must be clearly understood that pinching does not produce fruit buds on growth of the current year, not even upon such free-fruited Apples as Dutch Mignonne, Potts' Seedling, Stirling Castle, Lord Suffield, and Lane's Prince Albert. It is precisely when the trees have attained a useful size, say in the sixth year, that the advantage appears to be with the standards.

For example, and keeping to Apples, I have among half-standards Duchess of Oldenburg with plenty of fruit buds upon last year's growth, Worcester Pearmain and Newton Wonder with numerous terminal fruit buds, Ecklinville and Keswick Codlin with the young shoots absolutely bristling with fruit buds. Mr. Picker may be congratulated in calling attention to this matter. I hope to deal with pinching more fully shortly.—EDWARD LUCKHURST.

THE question asked by Mr. G. Picker is an interesting one, though it raises a side issue in the sequel—namely, that of extension *versus* restriction.

The philosophy of pinching is obvious. By preventing the tree from developing superfluous growths its strength is clearly husbanded and thrown into those parts that remain, which are thereby rendered stouter and more robust, as well or better capable of forming blossom buds and of bearing fine fruit.

The practice of stopping requires the exercise of that philosophy with judgment. The extent to which pinching may be carried out with advantage depends very much on the subject under treatment, its rate of growth, and many other local circumstances. Some practitioners advise close, others moderate, and others, again, as little pinching as possible consistent with keeping the respective trees within bounds, and preserving an evenly balanced head. This is scarcely to be wondered at when we consider that the matter of stopping has a wide and varied application, and also that different soils and localities have their particular influences on the varieties grown in them, so that the proper system of treatment must necessarily vary somewhat in detail.

The work of pinching, or summer pruning, should be practised with discrimination, conducting it with a view to preserving an equality and symmetry amongst the branches, and also at the same time promote health and fertility. This brings us to the crux of Mr. Picker's question, and I have pleasure in giving the outcome of a lifetime of experience.

Young trees, as I have noticed them, are invariably disposed to produce more branches than can have the space essential for proper development. Now, by thinning out the weak and misplaced growths, additional nourishment is supplied to the others, which may be allowed to develop and remain their full length, or only be shortened so as to preserve an equality of vigour and the desired form of tree. If a young fruit tree be grown on in this way without much cutting until it arrives at a bearing state, it has usually much cleaner and healthier branches, which of course produce the finest fruit.

When a young tree, on the other hand, has to be severely pruned in order to secure the requisite number of growths, and this system of close pruning has to be or is continued, it is hardly likely that the frequent and severe amputations will favour fruit production. If such tree be treated upon more rational principles, the side shoots not required for forming branches pinched to three leaves, and the branches merely topped to preserve the symmetry or even balance of growth, it will assuredly bear fruit earlier and of a much finer quality than were all the growths left. Your correspondent does not mean that sort of pinching, for he takes care to have an "open door" and mixes the orthodox method, intelligently carried out, with the senseless stumping system of manipulation.

By adopting a proper system of summer pinching, much good results to the branches retained, from their basal leaves being more exposed to light, they are the more effectual in the manufacture and storage of nutrient matter, and there will be less need of cutting in the winter. When branches are allowed to grow at will, particularly towards the centre of a tree, they frequently become too sappy, weak, and long for fruit-bearing, and they utilise sap for wood-production, which renders others unproductive. Neglect summer pruning in such case, and cut the worse than useless branches away at the winter pruning. What is the result? A number of shoots start in the spring following from the position where those of the previous year have been taken away.

Summer pruning or pinching mainly applies to trees that produce the fruit on spurs or short side branches, and they are pinched for the express purpose of causing the production or formation of blossom buds. It must not be done before the shoots have reached a certain degree of solidification, else the buds at the base develop growth of a woody nature the same season, instead of either remaining dormant or only

pushing a short, stubby, leafy growth—the true spur terminated by a prominent bud, in that or a future season developing into a blossom bud. In the case of Apples or Pears, to which your correspondent refers, the wood is solidified by the end of June to the middle of July for pinching, and if the leading branches are left unstopped, or merely topped to insure an equality of vigour and form, the side shoots then stopped will mostly form spurs, the sap being utilised for the formation of blossom buds.

Yes, pinching does promote the formation of blossom buds. (1) By concentrating the juices on the parts retained; (2) admitting abundance of light and air for the maturation of the wood and buds; (3) regulating the growth, so as to promote an equality of vigour and the symmetry of the tree.

But Mr. Picker does not mean this system of pruning, but the hard-and-fast mode of pinching to a given number of leaves or joints, and adhering to it under any and all circumstances, and with all varieties and kinds of fruits. I entirely agree with him on this point, for trees are often pruned into and kept in a state of unfruitfulness, whereas by adopting a different course they would become and abide fruitful. Still I hardly concede that his proposed experiment is a fair one. Many owners of gardens cannot adopt the non-restrictive system, but are bound by limit of space to have trees that can be kept healthy and fruitful under the restrictive method. With them it is not so much profit as growing their own fruit, as a relaxation and love of tending their own trees.

Unfortunately the race is now so much for returns in money that the lovers of fruit for its own sake are fewer than in former times. Private gardens, so called, are marketing establishments, instead of sources of supply wholly for home use, and bulk, not quality, has come into vogue, selection has taken the place of collections, and the choicest fruits as judged by the standard of quality have fallen into disrepute.

Still there are some persons who must grow fruit trees as cordons, espaliers, or dwarfs, or not at all, and they must adopt the dwarfing system. They practise root-pruning, and thus maintain a reciprocal action of roots and branches and grow splendid fruit. Many do not, I admit, because they prune the top into sterility and altogether neglect the roots. That is not the late Mr. Thomas Rivers' system, as propounded in the "Miniature Fruit Garden." Will Mr. Picker try this mode? He will get as many trees of the strong growing varieties into the same space as he does with the small growers, to which his plan would necessarily limit owners of small gardens. I do not see the propriety of this, as they are as much entitled to have Blenheim Pippin and Bramley's Seedling as they are to have Potts' Seedling and New Hawthornden Apples. The trees only occupy half the space on the restrictive as on the non-restrictive system, and the results are earlier and better for such proprietors.—G. ABBEY.

My experience is that, with Apples and Pears, the judicious method approved by Mr. Geo. Picker in this section of our fruit trees is conducive to the best results. Not so with others, of which more anon. To pinch, or not to pinch, is not the question, as stated by Mr. Picker, his opinion being "that the six trees merely pinched for training will produce more and better fruit in six years after planting than those for manufacturing fruit buds."

On one point only do I venture to differ from that hypothetical opinion—viz., in respect to quantity. As for quality, the common sense training he advocates is, to my mind, infinitely preferable to the severely restrictive measures as depicted *per contra*. Moreover, that, constitutionally, the freer grown trees will have, do have, distinct advantages over the others. But what is sauce for the goose is not sauce for the gander; and with respect to Peaches and Plums, I am a firm believer in the severer form of pinching. Not with the view of fruit bud production, which with these fruits is generally abundant, but for the all-round benefits conferred to the end of superior wood, and the chief end, of course, superior fruit from vigorous, healthy trees.

The finest Peach trees I ever saw grown outside (or inside, for that matter) were pinched so as to render pruning wholly unnecessary; it was the hobby of a good gardener, and his trees were examples never to be forgotten. Plums on walls I have trained on the same principle with the best results.—K., Dublin.

[We thank our correspondents for the admirable manner in which they have responded to Mr. Picker's invitation on page 317 of our last issue. It is clear that every writer possesses sound knowledge on the management of fruit trees, though it is naturally variously expressed. It must not be supposed that the communications are arranged in the order of merit, or anything of that kind, but simply in the order of their arrival. More will possibly be heard on the subject, and we will only say now that the "severer form of pinching Peach trees" advocated, will be, perhaps, the most startling idea to some extensionists, but we happen to know that "K." had an important charge in one of the finest gardens in Britain, and long famed for the cultivation of Peaches under glass. Without any intention of supporting this particular correspondent, we will state a fact of a not less uncommon

nature—namely, the finest and most fruitful Morello Cherry trees that it has fallen to our lot to see were clustered with spurs from base to extremity of their long, straight branches, the result, at least in great part, of summer pinching and pruning. This, as Mr. Luckhurst says, is an "exception" (to the rule in Morellos), though it seems to show that pinching, when done "at the proper time, in the right way," does not prevent the formation of blossom buds. It must be understood we are not recommending the system of closely pinching either Morello Cherries or Peaches for general adoption.]

SOUTH WALES NOTES.

Chamaerops Fortunei.—This dwarf ornamental Palm is quite hardy in the pleasure grounds here. There are two very fine plants growing in a large shrubbery close to the River Taff, which were planted some sixteen years since from 48-sized flower pots. They have grown well, and are now from 8 feet to 10 feet high, with large compact heads of strong healthy foliage. The stems are from 4 feet to 5 feet in length, and as thick as a man's body, densely covered with a matting of fibre so thick that no frost or cold can injure them. The plants have never had the slightest protection of any kind since they were planted, and we have had some hard winters. Sometimes the thermometer registered as much as 18° of frost, but it did them no harm, further than brown the tips of some of the leaves. The situation where the plants are growing is somewhat sheltered by trees and shrubs, and not more than 28 feet above mean sea level. The soil is a good sandy loam, in which trees and shrubs of most kinds grow well. Conifers in particular, and the best varieties of Hollies and Aucubas.

Choisya ternata is one of the most beautiful evergreen shrubs that is grown. It is perfectly hardy in this district, and makes large bushes in a short time. There are a great many plants of it growing in the shrubberies here, some of them as much as 10 and 12 feet in diameter, and 6 feet high, thoroughly furnished to the ground with flowering branches. It flowers profusely twice a year, and its pure white Orange-like blossoms and dark green ternate leaves produce a fine effect when in flower. It is easily propagated by cuttings, and it makes an excellent pot plant for growing in the greenhouse or conservatory.

Hydrangea hortensis is also hardy in this district. The plant grows rapidly in large bushes, flowers freely, and lasts a long time in beauty. It has a fine effect when planted in large beds by the sides of walks, or in single specimens in front rows of shrubberies. Besides, it makes a very useful decorative plant for the greenhouse or conservatory grown in small pots, with a stem not more than a foot high, carrying at top a pink or blue cyme nearly a foot in diameter, which stands for a long time in good condition. The proper way to grow these is to strike the cuttings singly in 3-inch pots in the month of August, and as soon as the plants have rooted well shift them into 5-inch pots, in which they will flower the following May or June. We grow some hundreds in this way annually, and not more than 1 or 2 per cent. at most fail to flower. After they have finished flowering they are planted out in the pleasure grounds, where they make a fine display in a year or two when in flower.

Aralia Sieboldi is perfectly hardy in this climate, but owing to the great size of its evergreen Ivy-shaped leaves, it requires to be planted in sheltered places, or the leaves will get injured by the storms in winter. We raise a number of plants from seed annually, and grow them in pots for house decoration until they get too big for that purpose, when they are planted out in shrubberies in the pleasure grounds. The plants flower freely outside, and have, when in flower, the appearance of a monster variety of tree Ivy.

Ceanothus Veitchianus.—This dwarf summer flowering shrub has proved quite hardy in this district during the last five years, planted out in the open, and without protection of any kind. The shoots are slightly pendulous in growth, it blooms freely, producing large clusters of bright blue flowers, which are very attractive, and much admired by all. The plant is not particularly fastidious as to soil, and will grow in almost any kind under ordinary treatment. It does well planted in beds on the lawn, or in mixed shrubberies with other flowering plants. *C. azureus* var. *Gloire de Versailles* is also hardy, but not quite so robust in habit of growth as the last named. Although it is hardy enough to stand out in the open unprotected, it grows much better when trained on the south side of a dwelling-house, than it does when grown in bush form in the open ground.

C. dentatus is a most beautiful variety, but it is not hardy enough to withstand a severe winter, not even with the protection of a wall. I had a very large plant of it growing on the south side of my cottage here. It grew well for years, and covered the whole side of the house, and during that time it flowered profusely every year, but a severe winter came and killed it to the ground and it never did any good afterwards. *Forsythia viridissima*, both in bush form and trained on walls, has been very fine here this spring.—A. PETTIGREW, Castle Gardens, Cardiff.

RECENT WEATHER IN LONDON.—A considerable amount of rain has fallen during the past few days. Saturday was dull, as was Sunday, though there were occasional glimpses of the sun. On the evening of the latter day rain commenced to fall, and continued until the early hours of Monday, when it stopped. About midday, however, it recommenced, and only ceased for intervals of varying length up to Wednesday morning, when at the time of going to press it was fine.

— WEATHER IN THE NORTH.—On four mornings of the week ending 24th inst., frosts of from 3° to 8° were recorded. Easterly winds have prevailed, and generally ungenial weather. Saturday, although the morning was decidedly frosty, and the former part of Sunday were more pleasant, but the afternoon of the latter day was again cold with bitter wind from the N.E. Monday morning was very wet but decidedly milder, with the barometer at 45°, although the wind was in the east.—B. D., *S. Perthshire*.

— ROYAL HORTICULTURAL SOCIETY.—The next Fruit and Floral meeting of the Royal Horticultural Society will be held on Tuesday, May 2nd, in the Drill Hall, James Street, Westminster, 1 to 5 P.M. At three o'clock a lecture on "The British and Swiss Alpine Floras" will be given by Mr. E. A. N. Arber, F.R.H.S.

— THE ESLINGTON NEAPOLITAN VIOLET.—Mr. Joseph Oliver having sent us a bunch of Violets, the flowers of which were so fine and pleasing in colour—a charming Cambridge blue, with a few of the petals approaching white—that we wrote to him respecting it. We are informed that it sported from Comte de Brazza's white Neapolitan some years ago at Eslington Park, and is found there to be "the strongest grower of all the doubles, and a larger edition of the old Neapolitan, possessing its colour and sweetness."

— STYLIDIUM CRASSIFOLIUM.—The genus *Stylidium*, though rarely represented in gardens, contains many curious and interesting species. Many of them are more at home in botanical collections, but there are a few species which have a decided horticultural value, the one under notice being of that number. Seeds of this were sent to Kew in May of last year by Sergeant-Major Goodby, and one of the plants raised is now in flower in the temperate house. Like most of the other species, it hails from Australia. It is of herbaceous habit, and forms a dense rosette of deep green, narrow, somewhat fleshy leaves, 6 inches long. From the centre of the plant an upright raceme rises to a height of 1½ foot, on the upper foot of which the flowers are produced, in groups of from two to four, at short intervals. The flowers are rosy-pink, with a darker blotch at the base of each petal. The under side of each petal is covered—as also is the calyx, bracts, and flower stalks—with a quantity of soft glandular hairs. When fully expanded the flowers are about half an inch across, measured the widest way. Like other *Stylidiums*, the column, which contains the stamens and stigma, is very sensitive, the slightest touch causing it to reverse its position.—W. D.

— THE ISLE OF WIGHT.—Daffodils are receiving much greater attention in the Garden Isle than they did a few years back. It is known to many that the wild or common Daffodil luxuriates in the copses of the Island, producing large and good coloured blooms in quantity. We are also favoured in a few places with the old double white trumpet Daffodil (*cernuus plenus*), with its flowers of great beauty. But apart from these, we find the cottagers, amateurs, and professional gardeners alike increasing their stock of varieties of *Narcissi*. The other evening I had occasion to visit St. Lawrence, and having a little time to spare, I called upon a friend (Mr. John Gell), who is a grower of acres of these lovely spring flowers, and the sight I beheld was truly wonderful, and few people in the Island, much less out of it, could conceive of the amount of business done at this time of year in this family of flowers at a remote place like St. Lawrence as is done by Mr. Gell. Several men were busily engaged bunching *Narcissi* in variety for all parts of England. In reply to a query respecting the demand, Mr. Gell said, up to the present, they had not had the least difficulty in disposing of what they could or did grow. The Daffodil exhibitions already held in the Island have been a great incentive to the lovers of a garden to take up the cultivation of these lovely spring flowers for which the Garden Isle is so suitably adapted.—S. H.

— JUDGES OF THE £100 GRAPE CLASS AT SHREWSBURY.—We have had several inquiries from Grape growers for the names of the Judges in the above great class at Shrewsbury, and have pleasure in stating that they will consist of Mr. Owen Thomas, V.M.H., Royal Gardens, Windsor; Mr. Malcolm Dunn, V.M.H., Dalkeith Palace Gardens, and Mr. W. Crump, V.M.H., Madresfield Court Gardens. It will be seen that England, Scotland, and Wales are appropriately represented, and we think the choice admirable. All are gardeners of the first repute in actual practice as growers of Grapes; they are also experienced adjudicators, and know well the points of merit, and otherwise, in the respective varieties. If such men do not inspire confidence it would be hard to find others who would, however capable and honourable these might be. We hope there will be grand competition.

— HORTICULTURAL EXHIBITIONS.—Some few weeks ago you kindly permitted me through the columns of the Journal to make a few suggestions re horticultural exhibitions, so as to give greater attraction to the public at large, and thereby insure their permanency where established, and encourage their formation in towns and country villages where they are unknown. I need not reiterate what I then said, but wish to suggest also the collections of specimens of fruits, seeds, flowers, and plants, to be arranged in show cases, with particulars attached to each specimen, that would be of interest and afford information to the inquiring observer; in fact, we may say, to have a horti-agricultural museum of specimens in connection with each exhibition, arranged in travelling show cases, so that they could be lent to any deserving object, or pass from one exhibition to another.—S. HEATON.

— SHIRLEY GARDENERS' ASSOCIATION.—At the last monthly meeting of above Society, held at the Parish Room, Shirley, Southampton, there was a good attendance of members, and Mr. B. Ladhams, F.R.H.S., presided. Mr. H. J. Jones, Ryecroft Nursery, Lewisham, gave a very interesting and instructive lecture on "The Begonia." The essay embodied directions for the successful cultivation of the plant both from seed and cuttings. Fertilisation was touched upon, and the essayist promised the result would be most interesting and possibly profitable. The lecturer considers that as a bedding plant the Begonia has no equal, especially if first carefully grown to secure dwarf strong plants. Exhibition plants also received a passing notice. At the close of the lecture there was a useful debate, and the meeting closed with a vote of thanks to Mr. Jones. There was a floral display by the members of the Association amongst which was a very fine plant of the new *Cineraria Stella*, shown by Mr. H. Wright, gardener to Mrs. Asten Smith.

— 96,000,000 PRIMROSE BLOOMS.—Few people who observed the ready sale which bunched "Prims," as they are named by the trade, secured on Primrose Day in the streets of London and other centres, possibly gave a thought as to the extensive nature of the business. From twenty reports from different leading cities just to hand, it seems that over 4,000,000 bunches of Primroses were despatched for sale to meet the requirements of Primrose Day. These bunches contained probably something like 96,000,000 blooms. Estimating 4,000,000 plants as being needed to give this yield, they would, set 1 foot apart each way in fields, occupy more than 90 acres of land. Of course the flowers really are gathered in woods, by the hedgerows, and in rural nooks, and the bulk come from the southern counties of England. As far as profit is concerned it is a question if they yield anyone but the flower girls a remunerative balance, for they are often sold in the markets as low as 3d. a dozen bunches. More Primroses came into London last week than for a corresponding period in any previous year. This was due absolutely to the increased demand for supplies for Primrose Day.—("Daily Mail.")

— DEATH OF MR. WILLIAM DICKSON.—It is with deep regret that I have to send you news of the death, at the early age of thirty-five, of Mr. William Dickson, of the firm of Messrs. Dickson & Sadler, chartered accountants, Liverpool, and late Secretary of the Liverpool Horticultural Association. Mr. Dickson had been ailing for many months, and hopes were entertained that he might possibly recover, but these hopes have proved groundless, and he passed away at his residence, 116, Huskisson Street, Liverpool, on the 19th inst., and was interred at St. James's Cemetery on Saturday last. Not only has the city lost a useful citizen, but the Horticultural Association must feel that while Mr. Dickson was able to keep in office they had a painstaking servant, who was thorough in his business transactions, and who did his best. Many friends who knew his personal qualities will unite with me in expressing sincere regret at the loss at so early an age of one who ever tried to do his duty. During the late Mr. Dickson's illness the work of the Association was carried on by his partner, Mr. Harold Sadler, who is now Secretary.—R. P. R.

The week has been characterised by dull weather and very cold mornings.

— **STRELITZIA REGINÆ.**—Few plants when in flower attract more attention than this old favourite. For brilliance of colour it has few equals, the contrast between the deep orange of one portion and the dark blue of the other being very striking. At Kew two examples are now flowering in the Mexican house, one carrying three spikes and the other six. The spikes are 4 feet in height, and bear about five flowers each. The flowers last in good condition from three to four weeks, and as usually there is a difference of two or three weeks between the opening of the flowers on the first and last spikes, the flowering season is prolonged for eight or ten weeks. Although it has been in cultivation upwards of a century, and was one of the first plants to be figured in the "Botanical Magazine," it is now but seldom seen, and then usually as a pot plant. At Kew it has been planted out in a border of loam in a house which has a minimum winter temperature of 50°, and it is there found to grow more vigorously and flower better than when grown as a pot plant.—W. D.

— **FLOWER TRAFFIC OF THE SCILLY ISLES.**—A competition (says the "Western Weekly") organised by the flower-growers of the Isles of Scilly, in the hope that the Great Western Railway Company would be induced to lower its rate of £8 10s. a ton to Paddington, was started in the spring, and has been keenly watched by the islanders. The flowers have hitherto been conveyed to Penzance by steamer, and thence by rail to London and other great markets. This year some of the Scillonians entered into an arrangement with Mr. Thompson to convey their produce from St. Mary's to the London and South-Western Railway Company's goods terminus on the Devonport side of Stonehouse Pool. This service commenced on March 4th, since which two ketches, the Agnes and the Mount Carmel, have been running two or three times a week. Leaving the Isles at nine o'clock in the evening, they have reached Devonport in time for the early afternoon express train for London next day, and each vessel has carried from 1000 to 2000 boxes of flowers, 160 of which go to the ton. It is claimed that there has been a saving in carriage of between £2 and £3 a ton.

— **ROYAL METEOROLOGICAL SOCIETY.**—The monthly meeting of the Society was held on Wednesday evening the 19th inst. at the Institution of Civil Engineers, Westminster; Mr. F. C. Bayard, L.L.M., President, in the chair. Mr. H. Mellish, F.R.Met.Soc., read a paper on "Soil Temperature," in which he discussed the observations from the thermometers at various depths in the soil which have been made at the stations of the Royal Meteorological Society. The records have been carried on at many of the stations since 1881, and observations have been made at the following depths in the soil:—2 inches, 6 inches, 1 foot, 2 feet, and 4 feet. It appears that in nearly all cases the annual temperature of the soil at a depth of 1 foot is slightly higher than that of the air. In winter time the air and the soil at 1 foot have about the same temperature, the soil being often a little warmer till about the end of January, after which, for the next two months, the air has a small advantage; but in the summer months the soil at 1 foot is generally warmer than the air, the difference exceeding 3° at several stations. Mr. Mellish shows that on the mean for the year the light soils are 1° warmer than the air, while the strong ones are only 0.2° warmer, and he is of opinion that near the surface we may expect to find wider extremes of temperature in light soils than in strong ones, but that the heavier soils are better conductors of heat.

— **AMERICAN APPLE EXPORTS.**—The total Apple shipments to European ports for the week ending April 1st, 1899, were, says a transatlantic contemporary, 13,414 barrels, including 7914 barrels to Liverpool and 5500 barrels to London. The exports included 2052 barrels from Boston, 85 barrels from New York, 2920 barrels from Portland, 6514 barrels from Halifax, and 1743 barrels from St. John, N.B. For the same week last year the Apple shipments were 18,173 barrels. The total shipments thus far this season have been 1,204,491 barrels, against 883,158 barrels for the same time last year. The shipments in detail to date have been 227,749 barrels from Boston, 154,270 barrels from New York, 137,593 barrels from Portland, 406,705 barrels from Montreal, 226,241 barrels from Halifax, and 51,993 barrels from St. John, N.B.

— **DUMFRIESSHIRE AND GALLOWAY HORTICULTURAL SOCIETY.**—An interesting exhibition of Daffodils and other spring flowers was held by this Society in Dumfries on 18th inst. The season in the South of Scotland has been an unfavourable one for early flowers, and comparatively few of the local growers were able to exhibit. Some lovely flowers were, however, sent by others. Messrs R. Smith & Co. of Worcester sent a number of Daffodils representative of the various sections, with a collection of other early flowers. Messrs. Barr & Sons of London showed a fine collection of Narcissi, many of which were new to the greater number of those who visited the exhibition. Messrs. Hogg & Robertson of Dublin sent about forty varieties grown in their bulb nurseries at Rush, near Dublin. These were much admired. Mr. W. B. Harland's, of Cork, flowers were over for the season, but his penderosa, a double Daffodil, was exhibited and viewed with interest. Mr. Service, Maxwelltown, and other local trade growers, had miscellaneous exhibits of much value. Mr. James Davidson of Summerville, Mr. J. Primrose of Arundel House, and other private growers, added much to the exhibition by their Orchids and hardy flowers. Mr. Davidson's Masdevallia Harryana was greatly admired. The exhibition was followed by a lecture on Daffodils by Mr. S. Arnott, Carsethorn. Mr. W. J. Maxwell, late M.P. for Dumfriesshire, occupied the chair. Mr. Arnott's paper treated of the literature, history, and cultivation of the Narcissus. A running commentary upon the varieties was given in connection with the description of the sections into which the flower is botanically divided. Probable improvements in the flowers were also touched upon in a suggestive way. An interesting discussion followed, and Mr. Arnott was heartily thanked for his paper. Votes of thanks were also given to the more prominent exhibitors.

— **EXPERIMENTAL FRUIT GARDENS.**—We take the following announcement from the Report of the Agricultural Sub-Committee of the Herefordshire County Council:—Recognising the dearth of really competent persons to undertake pruning and grafting, it has been decided to establish experimental gardens in various parts of the county, in which to provide instruction in raising, grafting, budding, pruning, and training of all kinds of fruit trees. To commence with, each garden will have an area of an acre, be provided by the landowners, who will use the sites as nurseries for their own estates, and merely place them at the disposal of the Committee for educational purposes. Teachers will visit these gardens at the proper seasons, and as often as necessary, to give demonstrations in the various processes to the public, and special individual instruction to such as are desirous of qualifying for a County Council certificate. This will be given after an examination, which will be partly practical and partly theoretical. The theoretical examination will be by means of written papers, or *vice versa*, according to the capabilities of those presenting themselves. No person will therefore be debarred on account of any lack of previous literary training. Although the only cost to the Committee will be the provision of the instruction and the conduct of the examinations, it is hoped that these gardens will not be altogether valueless to those gentlemen who provide the land; but whatever the result may prove to be, several landowners have entered upon the experiment *con amore*, and there are not wanting signs that plenty of plots will be available as the scheme becomes better known. The sites already accepted are at Hope-under-Dinmore and Bodenham, kindly offered by Mr. Arkwright; Elton and Downton, by Mr. Boughton Knight; Bryngwyn, by Mr. Rankin, M.P.; Putley, by Mr. John Riley; and Thinghill, by Mr. John Smith. [Herefordshire is the greatest orcharding county in Britain, but vast numbers of trees are in a deplorable condition. The teaching projected seems to be very appropriate, and ought in time to be highly beneficial. We are pleased to see that all the proposed examinations are not to be in the form of written papers, as we happen to know of skilful workers who are unable to do anything like justice with the pen to their practical abilities, while others by its skilful use can do a great deal more than justice to themselves as efficient and profitable workers.]

LONDESBOROUGH PARK.

THE writer who essays to give a complete and accurate account of the most interesting and instructive phases of the horticultural and arboricultural life on this magnificent domain will find before him a most difficult task, and one which will take long in fulfilling. He will be compelled to delve 200 years or so into history, and proceed thence step by step to the present day. The records will be of more than passing interest, and the sidelights, as it were, that will be opened up for observation, so rich in variety, that the pages of the *Journal of Horticulture* would not suffice for their accommodation. It may therefore be affirmed at the outset that this home of the Earl and Countess of Lonsborough will not be treated on such broad lines, but be confined to notes of the gardens as they are to-day, or rather as they were when this visit was paid in the summer of last year. It is many months over which to carry the mind, but the features of Lonsborough were such as to leave an indelible impress on the memory. The two gardens separated by the splendid park can be clearly seen, and both will have reference made to them in the succeeding paragraphs.

pulled down in 1819, by William Duke of Devonshire, the representative of the family at that period. The extensive cellars remain intact, and the original flight of steps, leading from the park to the front entrance of the house, may still be seen, flanked by columns supporting graceful urns. The grand stone pillars of the gate leading from the village also remain; but now, on passing through them, instead of the ancient Hall, we come upon the green level of the beautiful lawn, bounded by lovely flower borders, which, with their mass of richly mingled colours, are a delight to behold.

"The lawn and flower beds are surrounded by rows and avenues of stately Yews. One of these avenues is of great length and solemn dignity, and is known as "Garriek's Walk," that great actor having been a friend of the third Earl of Burlington, who for fifty years—from 1703 to 1753—was the owner of this estate. Richard, the third Earl of Burlington, was famous as a lover and patron of literature and art, and was the builder of Burlington House in London. He was also a landscape gardener, planning or altering the grounds at Lonsborough, and in this capacity is immortalised by the great poet, Alexander Pope, who was a friend and visitor of Lord Burlington. It is interesting to think

FIG. 77.—A WATER SCENE IN LONDESBOROUGH PARK.

To reach the pleasure grounds from the vegetable and fruit gardens means to traverse more than one or two hundreds of yards—in fact, it is quite a journey, but such a one as always seems all too brief. It is magnificent park land the whole way, with noble trees and charming water scapes scattered about its broad acres. The ground rises and falls in pleasant undulations until the lawns and pleasure gardens are actually reached. The characteristics of these are many and varied, as they may well be, considering the area of ground that is covered. There are great beds and borders of hardy flowers, whence vanloads of flowers might be readily secured; splendid trees of many kinds and sizes; avenues of Elm and Yew; water scenes in which strange and well known waterfowl find a home; wide areas of Water Lilies; shrubs grown for their handsome leafage, and others for the beauty of their flowers; and so one might go on. It is fortunate, however, that we are able to give readers a few words on this portion of the estate from the fluent and graceful pen of Canon Wilton, who, holding the living of the church within the park, is able to speak authoritatively and withal entertainingly of the beauties he so much admires. He writes:—

"The old garden at Lonsborough, generally known as the pleasure grounds, may be said to be unique for historical interest and picturesque beauty. The central space, now forming a fine tennis lawn, was formerly the site of the ancient home of the Cliffords, until the house was ruthlessly

that Pope and Garriek, and many an eminent man of that day, have ascended those grey steps, and wandered in these beautiful grounds.

"From those steps you look down upon a broad avenue of Elms, leading to the large lake in the park—the last of a succession of sheets of water, fed by copious springs and adorned with cascades. Other avenues converge to the steps, from which may be seen the clumps of trees crowning the wolds, known from afar as the "Lonsborough clumps." But it is from the great gates at the farther end of the pleasure grounds, approached by winding walks and shadowy glades, that the principal avenue may be seen—a far stretching vista, through magnificent clumps of Elm, and Beech, and Oak. You look down this long avenue to the distant horizon, where Selby Abbey Church is visible, near Brayton Barff; and again, to the right you see against the sky the towers of York Minster, and to the left the wolds of Lincolnshire, with the broad Humber at their feet. From the fine gate at the head of this stately avenue (only to be rivalled at Windsor or Badminton) there is a gravel drive under lofty Limes to the central space of turf and flowers, before described.

"Mention should be made of the rockery, covered with rare plants, which surrounds the entrance to the cellars. There is also a remarkable

rock garden, adjoining the church, in which the skill of Mr. McPherson, the able and indefatigable head gardener, in arranging the stonework and flowering plants, is conspicuous. This is a new and striking feature of the pleasure grounds. In the centre of it is a fountain, with Water Lilies, under which you catch the gleam of goldfish. The Earl and Countess of Londesborough take the deepest interest in every detail of the old garden, and also of the noble, well timbered, undulating park, in which stands their picturesque house, festooned with creepers, and surrounded with trailing Roses and arches of purple Jasmine. On the slope below the house are beds of flowers, beyond which is a little lake, where the stork and crane and black swan and innumerable rare waterbirds may be seen disporting themselves under the spreading Beeches."

It would be nothing less than a waste of time to pass again over the road the Canon has so charmingly traversed, for it is certain we could not add one iota to its interest. We may, however, before returning to the more utilitarian portion of the estate present two photographic illustrations that have been provided for us by the kindness of Mr. McPherson. It will be seen that one (fig. 77) is a water scene with trees

well worthy of close examination. One of the best crops at the time of this visit was seen in the Tomato houses, in which were hundreds of plants in the best of health and condition. They were carrying immense numbers of fruits, none of which was large, but ranged about medium size, and were smooth in shape. From such fruits there is no waste, but the greatest possible depth of flesh in proportion to the size of the specimen. The variety is one of Mr. McPherson's raising, and he adheres to it because he can find no other that better answers his purpose. The demands upon his resources are great, and it is not likely that too many Tomatoes will be produced. Cucumbers again were in the finest condition, and bore their straight fruits of moderate length in quantity. Such are desired in preference to fewer specimens that are individually of larger size.

In a long and lofty case against one of the walls was a magnificent show of Peaches and Nectarines—not one or two fruits, but hundreds in excellent condition. No one could wish to see trees in better health than those, and it was perfectly obvious that their requirements were thoroughly understood, and their wants promptly supplied. Healthy wood and

FIG. 78.—IN THE PLEASURE GROUNDS OF LONDESBOROUGH PARK.

and hills in the background; fig 78 shows quite another aspect, and illustrates two of the broad borders of herbaceous perennials to which reference has previously been made.

A portion of the gardens, in which an abundance of splendid produce is grown, is very old, but several of the glass structures have been either renovated or renewed, and the department is admirably managed and equipped. The walled garden in which they are located is quite picturesque, which is more than can be said of many places that are devoted to vegetables and fruits, and which are often severely plain. The stream that passes through between broad grass verges, and the many hardy flowering plants that have to be accommodated, lend an air of attractiveness that might well be extended to other similar places. Even the old walls and buildings add to the effect which would probably be detracted from by modern erections—at any rate, from a picturesque point of view, though they might be increased in value if the standpoint of the severely practical be adhered to. It is better as it is—the practical and useful in association with the ornamental and the beautiful.

Under glass the useful preponderates, as space is too valuable to permit of the purely ornamental occupying it. Everything is grown with a view to being put to some use, and consequently the houses are

leaves, with the beautiful fruit, were living testimony to this. Mr. McPherson's motto may apparently be summed up in one word, and that is "thoroughness." The vineries and their occupants are in the same creditable condition, and though they have been compelled to do good work in the past, they look in every respect capable of maintaining a similar standard in the future with the skilled treatment to which they are subjected; and so it is with everything in the houses, whether they be fruits and vegetables, plants grown for their foliage or their flowers—each has individual attention, and is accorded, as far as possible, exactly the treatment that is most conducive to the best results. In the frames the same conditions prevailed in the varied occupants, which renders repetition unnecessary.

Out of doors a comparatively new fruit garden is rapidly attaining to profitable condition, and will probably be producing splendid crops before many more years have passed away. The trees are numerous, and were, when seen, conspicuous mainly for their excellent form and the cleanliness of the whole of the growth. Naturally some were superior to others, but there was little or nothing to cavil at in the collection as a whole. Those in the older garden, both in the open and on the walls, were equally as creditable, but they had not the glow and vigour of youth as with the new. Pippin and stone fruits, with Currants, Gooseberries,

Raspberries, and Strawberries, were all represented in greater or lesser numbers, according to the requirements of the establishment and their suitability to the position and the climate. No attempt will be made to name varieties, or to compare this with that, as such a course would necessitate each fruit being taken separately, and a special article being devoted to every one. There they were last year, and remain now, and it is more than probable that to the really interested Mr. McPherson would be ready to open up the stores of his knowledge and illustrate his remarks with living examples.

Notwithstanding the unassailable fact that the attention given to the fruits, flowers, and vegetables within doors is of the best, there is no diminution in the careful details when hardy vegetables are concerned. There is a certain amount of ground, and if sufficient crops of all sorts are to be forthcoming at the proper time, every foot of it must be brought into requisition, and be made to produce the best possible results. The consequence is that the land is thoroughly tilled, and as the stores of available food become exhausted they are replenished again and again. It is by such methods of procedure that the practical gardener continues year after year to do such excellent work in a department that is now unfortunately regarded as not demanding any special knowledge or ability. But for the present no more can be said, save to express the pleasure and profit that the visit brought, and to thank Mr. and Mrs. McPherson for their kindly reception.—H. J. WRIGHT.

CULTIVATION OF BEET.

BEET is a crop which does not under ordinary circumstances require sowing earlier than the beginning of May. The seeds ought not to lie long in the ground after sowing, for they are liable to rot should the ground be cold and wet. If sown in May sunny days will heat the soil sufficiently for germination, and by the time the late spring frosts are over the young plants will be above the soil, and advance rapidly in growth.

The details of culture are simple, and it is no difficult matter to grow roots of serviceable size, and at the same time secure them of good shape and colour. With regard to colour, the small roots, if fairly well grown, are the richest. In an open position handsome, profitable, and useful crops of Beet may be grown providing the soil is suitable and properly prepared. In addition to being open the position must be warm, though not where adjoining trees may cause shade, and be drained. Though Beet likes a rich staple it does not succeed in the best manner in recently manured soil. There may be no apparent difference in appearance of foliage, but when the crop from soil which has been manured near the surface is lifted it will be found that the roots are in numerous cases ugly, forked, or coarse. Probably in some soils the roots may be cankered; such produce is neither desirable nor profitable.

To obviate these results the ground for growing Beet ought to be chosen where a previous crop has been grown with a liberal amount of manure. The manuring and preparation of the ground for Celery form an excellent foundation for the Beet crop. The ground should be well broken up two spades deep after the Celery has been used, no manure being added. Failing this sort of ground, thorough preparation ought to be made of another plot, trenching it two spades deep, and placing the manure used at the bottom. Broken up and pulverised soil is friable and mellow for sowing.

Sowing thinly in drills, and not dibbling in the seeds, is the best method, as they can be placed at an even depth. Draw the drills 2 inches deep, and scatter three seeds at distances of 9 inches along each drill, or the seeds may be sown thinly along the whole length, eventually thinning the seedlings to 9 inches. The drills must be a foot apart to allow room for the cultural operations of hoeing and weeding, and afford space for the spread of the leaves. The thinning must be carried out early. If there are blank spaces it is useless to fill them up with thinnings, as these never develop fine roots. It would be better to resow, or leave the spaces unfilled. Hoe the ground as soon as possible to destroy seedling weeds. Those coming up with the plants should be abstracted when thinning. Persist in the hoeing until the growth of the plants will permit of no more being done. In dry weather a light application of salt may be hoed in along the rows, as Beet is a seaside plant naturally.

In well-prepared soil Beet needs no water during the whole course of the summer. Should dry weather occur the tap root will descend further in search of moisture in the subsoil. Where rich light loam does not exist in gardens, but only a stiff unkind clayey material, Beet may be grown by making deep holes with a crowbar, and filling these with good sandy compost, sowing seeds on the surface, and eventually thinning to the best plant.

On shallow soils round Beet may be employed, as there will not be depth enough for the long-rooted varieties. Dell's Crimson is still one of the best varieties of long Beet, and the Globe an excellent round variety.—E. D. S.

AMERICAN BLIGHT.

WHEN I wrote the few notes published in your issue of the 13th inst. (page 298), I hoped that someone would take the matter up, and give their experience upon the subject of blight-proof stocks, and I am amply rewarded by the very interesting notes which you, Mr. Editor, have appended. I do not know that your remarks need any reply from me, for although you differ from me in experience there is nothing new about that, as experiences often differ, and it is only by comparing experiences and results that facts are arrived at, but I think I might just say a word by way of explanation.

Although you carefully guard against the reader gathering that Crab stocks are better than Paradise for growing trees which will resist the attacks of *Aphis lanigera*, yet I fear the casual reader might draw that inference; and whilst I do not say that trees worked upon Paradise are free from attacks, I do most distinctly affirm that under ordinary conditions they are much less liable to them.

The trees you mention were scarcely in a normal condition, being in a hot and dry situation, and as everyone knows, trees that are in anyway rendered unhealthy are the happy homes of insect life. The trees instanced at Chiswick are likewise growing under conditions most favourable to insect attacks, being in an impoverished and excessively dry soil.

But another question arises. We are agreed that the woolly aphid thrives better on some varieties of Apples than upon others, may not the various kinds of Paradise which are used as stocks exert a somewhat different influence upon the Apples worked upon them? I know of five kinds of Paradise which are used as stocks, and some of them vary a good deal in habit and appearance. Very possibly trees worked upon some of the weaker growing varieties may be more liable to attack than those worked upon the more robust ones.

Once more, Mr. Editor, had the Mistletoe anything to do with making the trees blight-proof? Is it possible that it had affected the tree so as to make it distasteful to the next parasite?

Lastly, you say that I do not state with what success I have waged war with the enemy. I thought it would be out of place for me to do so, but you most kindly supplied the deficiency by saying that "the trees received were clean."—A. H. PEARSON, *Chilwell, Notts*

[As affording proof of our readiness to publish records of experience on the subject of "blight-proof stocks" for Apples, we insert a note from an experienced grower of many varieties of Apples in support of Mr. Pearson's proposition that the Duchess of Oldenburg is with him free from attacks of the American blight. This, however, is not a case of stock, but of *scion* deterring the enemy; and for all Mr. Pearson said to the contrary on page 298, it was so in trees of the Duchess under his own observation.

This view of the case we can understand on the ground that the leaves, and not the roots of the tree, having paramount influence in determining the character of the juices peculiar to varieties, and which juices may be more or less objectionable to the trees attacking foes. This Mr. Pearson seems to admit by his suggestion of the Mistletoe affecting a tree, so as to "make it distasteful to the next parasite." As a matter of fact, neither the Mistletoe nor the tree's own roots saved the branches from attack. The woolly aphid is on it now. It was left there last year to see if it would pass to the Mistletoe. So far it has not done so, nor will it to any Apple trees within sight, for not one is to be seen.

Mr. Pearson raises another legitimate question—namely, that some of the weaker forms of the Paradise stock may so enfeeble the growth of the weaker-growing varieties as to render them more liable to attack than if they were making better growth on stronger stocks. There may be something in this, but if there is he cannot very logically stop at the Paradise. We know of trees that have been more or less weakened by bearing which are much more persistently attacked by the pest in question than are others growing by their side, but younger and much stronger, on both Paradise and Crab stocks.

The trees previously referred to that were experimented with till they were burnt were all on the same kind of stock—a rather broad-leaved form of the Paradise. They were, like trees obtained from Chilwell some years ago, clean. Not an insect was seen on them the first year, sheltered as was the position, and we quite believe they did not bring the enemy with them.

How and whence did it come? Perhaps on the wings of the wind from an ancient orchard half a mile away, but much more likely on the wings of those (by some) much loved birds—sparrows. We do not blame the stocks at all, and do not believe they had anything to do with the invasion, but we found out that some varieties of Apples were preferred to others by the enemy. As a matter of fact we became more interested in the progress of the woolly aphid than the trees. Duchess of Oldenburg was the last to be seized upon, but fell a prey at last, and then came the clearance and the fire.

We can understand well grown young Apple trees on a good form of Paradise making shorter, firmer, sounder growth than the varieties

might produce on the deeper rooting Crab, and the insects being tempted by the softer growths, but we cannot understand how and why varieties of Apples on the "Northern Spy stock" (and that was the original question) being invulnerable to the American blight, and we suspect no one in England can tell us; but we could very well understand that the Spy itself would be free on whatever stock it might be established.

As Mr. Pearson truly says, trees at Chiswick are, "growing under conditions most favourable to attack," yet there is one tree in it always clean—the Spy; while its neighbour, of another variety, is always infested with the filthy "blight," or would be if not doctored. Does Mr. Pearson attribute the immunity of the one and the infestation of the other to the stocks on which they are established? We do not, and should be surprised if the Spy is either on its own roots or the Paradise.

We should like to see grafts taken from the filthy tree and inserted in the Spy, also *vice versa*, and then would soon be shown whether the scion or stock had the greater influence in repelling the attacks of *Aphis lanigera*. There will be a new Chiswick some day it is hoped, but the old one will perhaps linger on long enough for testing the matter, and in the meantime we may possibly have light from young New Zealand.]

AMERICAN BLIGHT AND APPLE DUCHESS OF OLDENBURG.

I can endorse what Mr. Pearson says as to the Duchess of Oldenburg's immunity from attack of woolly aphid, for out of seventy trees thirty years old and under, not one has suffered, but they are addicted to both hard and soft canker, which is a thousand times worse. Old or young, in virgin soil or old garden, light or strong, it is the same story—canker. Yet for all this it is one of the most profitable Apples according to the experience of—C. C. ELLISON.

THE APPLE BUD MOTH.

My Apple trees are infested with the little brown caterpillars of the bud moth (*Tmetocera ocellana*), a common pest in America, and in some parts of Europe, but only once before this year brought to the notice of Miss Ormerod. It happens that the specimens then obtained (from which moths were developed and identified) were found in Hornsey by Mr. Oliver E. Janson, in 1889, and my garden is in Hornsey parish. He found the young leaves stunted and shrivelled, instead of fully expanded, and by the end of May all the shoots on infested trees had withered.

The caterpillars have recently hatched, and are now about a quarter of an inch long, brown, with black heads and a black plate on the next segment to the head. They have three pairs of claw feet near the head, four pairs of sucker feet in the middle of the body, and one pair at the tail. They spin the leaf and blossom buds together with silken threads, and feed upon them, leaving them brown and worthless. As described by an American writer, Apple trees after being badly attacked look "as though a fire had swept quickly through them."

Now, I believe that I saw the results of this insect attack in several parts of the country last year in the plantations of fruit growers, who were at a loss to account for the seared appearance of their trees. In my own garden I found the caterpillars, but could not identify them, or get them identified: and I noticed the results as above described.

My object in sending this letter for publication is to induce fruit growers to hunt in curled-up leaves, or shoots bound with silken threads, for this little brown caterpillar, and to communicate the results of their search to your columns.

I believe that injury to Apple trees attributed to frost is sometimes due to this mischievous grub, a capital picture of which, and a description of it and its life history, may be found in Miss Ormerod's "Report on Injurious Insects for 1899," recently published by Simpkin, Marshall & Co., at 1s. 6d.

I identified my specimens from a description given in that capital work, "The Spraying of Plants," by E. G. Lodeman of Cornell University, U.S.A., published by Macmillan, which every fruit grower should possess. Miss Ormerod has provisionally confirmed my identification, though she desires to see some of the moths hereafter to give certainty to the conclusion.—WILLIAM E. BEAR, *Highgate*.

[We shall be glad if our readers who may observe the symptoms described will send us specimens of rolled Apple leaves containing very small caterpillars. The invader, which we have seen, is illustrated and clearly described in Miss Ormerod's report mentioned by Mr. Bear.]

"FAMILIAR WILD FLOWERS."—Part 4 of this admirable work contains coloured plates, with explanatory letterpress, of Tutsan, Corn Sow Thistle, Greater Willow Herb, Hawthorn, Flea-bane, Touch-me-not, Bindweed, Hop Trefoil, Wood Sorrel, and the Yellow Rattle. As we have before stated, Messrs. Cassell & Co. are the publishers, and the price per part is 6d.

KINGSTON CHRYSANTHEMUM SOCIETY.

THE Committee of this old Society, whilst somewhat reducing the number of classes (open) for incurved Chrysanthemums, have, for the purpose of defining what varieties are meant by the term "incurved," now agreed to adopt the N.C.S. classification for the guidance of both exhibitors and judges. Whilst the old cup class for twenty-four Japs and twenty-four incurved, always an unsatisfactory one to judge, because these flowers differ so much in character, has disappeared, the champion class for thirty-six Japanese, with valuable money prizes attached, should prove to be much more popular and attractive. In addition to former Japanese classes, open, the Committee have added others for twelve incurved Japs and twelve reflexed Japs respectively, and they will also have open classes for six white, one variety, six yellow ditto, and six of any other colour. So that good growers have much to invite their hearty co-operation. It is naturally hoped that, being the oldest society in the county, Surrey growers will largely compete.

Although the complete schedules cannot be ready just yet, slips containing all the classes are to be sent out to exhibitors at once. Some grievance having been made last year in connection with the introduction of corks and mirrors into a plant group, it has been determined to exclude everything artificial, as also ribbons or other showy accessories, from the Chrysanthemum baskets, and in connection with the new class for dinner table, for lady amateurs, to exclude Orchids, that all competitors may be placed on the same footing.

BELETED POST-OFFICE PLANTS.

A NICE little problem for the Post-office to answer is propounded by Messrs. Wells & Company, Chrysanthemum growers, of Earlswood, Surrey.

For some years this firm has been endeavouring to build up a connection with Italy and Germany. The firm finds no difficulty in getting plants from the Continent swiftly and safely; but when they send plants to Italy or Germany they are troubled by inexplicable delay and ruined roots. Within two days plants can reach England. From the correspondence and vouchers which Messrs. Wells have sent to the "Daily Mail" it appears that from a week to a fortnight is needed to reach the Continent.

The British Post-office throws the entire blame on the Italian and the German authorities. Would it not be possible for the Government to do something to awaken the Continent?

EXPERIMENTAL HORTICULTURE.

I GREATLY appreciate the reference made on page 301 of the *Journal of Horticulture* of my paper on "Experimental Horticulture," which appears in the current issue of the Royal Horticultural Society's Journal, and am pleased to find that your views are in accordance with those to which I have given expression in my essay.

I find, however, that you are under a misapprehension regarding what I have said with reference to the experiments conducted under the auspices, for nowhere have I suggested that "the results of County Council experiments on allotments should be reported to the R.H.S. for collation." On the contrary, I not only state in the quotation you were good enough to make that experiments should be conducted on land of uniform quality, but show my appreciation of the variability of land devoted to allotments by stating in the next sentence that "it should be obvious that the results obtained from land that differs in its area, as does that of a group of allotments, cannot give trustworthy information."

The misapprehension may have arisen through my having used the term experimental plots instead of experimental stations in my reference to what is being done by County Councils, and I did so because the areas devoted to experimental purposes by these bodies hardly warrant the latter designation. With reference to this branch of the subject, I said, after alluding to the Chiswick garden of the Royal Horticultural Society, the experimental fruit garden at Madresfield Court, and the fruit farm at Apsley Guise:—

In addition to these, experimental plots and gardens have been established by several County Councils, and good work is being done at some of them; but as yet they are too few and isolated to exercise a material influence upon the advancement of horticulture. I am, indeed, persuaded that they will not give an adequate return until they are brought into close touch with each other, and joining hands engage in

experiments which, to be useful, must be conducted over a wide area, and consequently under divergent conditions of soil and climate. To bring the experimental plots belonging to County Councils into union, to formulate the experiments to be conducted on them, and to collate and prepare the results for publication, must of necessity be the work of some central body; and I submit that it is work in which the Royal Horticultural Society might engage with advantage to itself and to the whole horticultural community. The Society would, I believe, be perfectly willing to undertake the work if the County Councils would only consent to be guided thereby.

I have long been impressed with the importance of more exact information than is at present available on the effect of manures upon the various fruit and vegetable crops under the widely divergent conditions of soil and climate that exist in the United Kingdom; also information on the suitability of the several kinds and varieties for the different districts and various soils in them, and this information can only be obtained of the exactitude I have in view by experiments formulated by a central body and conducted under its auspices in the various authorities. We have a good general knowledge of these matters, as proved by the splendid results that are annually obtained in the gardens of all classes. But in the interest of the ever-increasing number of amateurs and the additions that are being annually made to the ranks of professional gardeners, it would be an immense advantage to have the information in a readily accessible form, and thus enable the cultivator to more readily adapt his practice to the conditions which obtain in districts in which he has not had experience than is now possible. This of course is one branch only of the comprehensive subject dealt with in my paper, and the time at my disposal did not permit me entering so fully into details as I could have wished.—GEORGE GORDON, *Kew*.

[After all, our "misapprehension," if such it be, of the observations of our friend in his excellent paper, was not of a very serious nature. He said that "when trials of manure are made care should be taken to select land of uniform quality, for where experiments are conducted on lands that were cropped and manured in several different ways in the previous year the results are, if not entirely misleading, of no practical value." In those observations we apprehend Mr. Gordon stood firm on the bed rock of Science; but we cannot help thinking he stood much less firmly, if on a rock at all, when he suggested that the results of experiments on County Council plots should be collated by the Royal Horticultural Society, because he further said, "The results obtained from land that differs in its area as much as does that of a group of allotments cannot give trustworthy information." What, then, would be the use of placing a mass of untrustworthy materials before the R.H.S. for collation? All that could be done after enormous labour would be to determine the average of the untrustfulness, and we think the Society can do more useful work than that. As a matter of fact, experiments conducted on a large group of allotments are of great, direct, and immediate service to the workers on that particular land, and of very little use elsewhere, where the land is of an entirely different character. Such experiments cost little and do great good to the particular class for whom they are intended, and they do not, in our opinion, come within the scope of the work of the R.H.S., as set forth by Mr. Gordon, in "encouraging the advancement of the higher branches of horticulture."

Experiments may be, as they have been, of great general value when conducted over a series of years on a strictly scientific basis, but is there not just a danger in these days of publicity of the experimental hobby-horse being ridden too hard? We have too much admiration for Mr. Gordon's ability and zeal to knowingly misrepresent him, and we only differ from him in opinion on the one point indicated in his extremely able paper in the R.H.S. Journal.]

"VELTHA" AND TOMATO DISEASE.—We notice that in your correspondence columns on page 308 an inquiry from "C. A." as to the method of treating diseased Tomato plants. We think it right that the public should be made aware of the fact that we prepare a remedy for all kinds of fungoid diseases, and have had most encouraging reports from Tomato growers of the success of this remedy in cases of sleeping, flagging, scab fungus, and kindred troubles of Tomato plants. "Veltha," as our preparation is styled in advertisements in your columns, is administered as a top-dressing to the soil during or after rain, and forms the simplest and cheapest remedy for every form of fungoid disease that has ever been put upon the market.—WILLIAM WOOD & SON, Ltd. [We shall be glad if "C. A." and other growers of plants of any kind liable to infection by fungoid enemies will give "Veltha" a fair trial. It is advertised towards the end of our last week's issue. We shall be taking a decided step in advance if extended experiments show that applications to the roots of plants prevent the spores of fungi which fall on the foliage or fruit germinating there, and taking possession of the tissues; still, if the resting spores can be killed, that would be, paradoxically speaking, yet not the less certainly, going to the root of the matter.]

GARDENERS' PROSPECTS AND "UNIONS."

HAVING been a reader of the *Journal of Horticulture* for a good number of years, I have thoroughly enjoyed the articles written from week to week, and certainly was delighted with the number of a few weeks back, and its portrait gallery. I have always found there was something one could learn from the opinions of others. Therefore, I feel it my duty to advocate the reading of some good gardening paper to all my young friends who are thinking of making gardening their profession.

But when asked by one of these youths, "What prospect is there before me if I follow this work up?" I feel the question a difficult one to answer, because it is certain that all such students cannot obtain good positions as head gardeners, and therefore those who do not must be content with a low wage in comparison with what may be earned by other classes of workmen who have been taught a good trade.

The chairman of an institution where youths are taught various handicrafts said to the writer a few weeks ago, in reference to teaching youths professional gardening, "the game was not worth the candle, as compared to that of teaching such a trade as carpentry. Certainly, a fact that has to be faced is this, What is the outlook for many gardeners who as they get older and have families around them? Nothing perhaps but toil, and toiling all their days, and frequently, when "turning grey," but still strong, having to be superseded by younger men.

How this is to be avoided I fail to see. A friend asks, "Why don't gardeners unite, and cause wages to be better?" But that is easier said than done. Many will, no doubt, have to look forward to the help they can obtain from such societies as the Royal Benevolent Fund, and the old age fund of the Horticultural Benefit Society. Well, these valuable institutions no doubt help their own members, and hence the necessity of every gardener who has no certain provision for the future belonging to one or other of these excellent societies, if not both. Indeed, I should like to see a larger number of gardeners who are in good positions supporting these institutions for helping the less favourably circumstanced but worthy fellow men; while not less should I like to see the time arrive when gardeners will be as much sought after and as well recompensed for their skill and labour as carpenters and other trade workers are to-day.—A. J. B.

[We have to say for our correspondent—1, That he practises what he preaches regarding the valuable institutions mentioned; 2, That as a teacher of gardening to youths the fact is forced upon him that much of his labour may be in vain, inasmuch as not more than a small moiety of the students can rely on future positions equal to those of carpenters; 3, That his common sense, resulting from much thought and long experience, does not enable him to see anything else than the utter futility of men who hope to be gardeners "uniting" to "cause wages to be better."

We are in substantial agreement with our correspondent on all points. The institutions mentioned towards the close of his article have been of enormous value to many gardeners (or their widows), and will be to more who through their safe and sound agency make provision against unfortunate contingencies.

While it is one thing, and a good thing, to teach youths the principles and practice of increasing the soil's productiveness, and obtaining from it the greatest amount of food, in order that the knowledge gained may be serviceable to them in after life, whether they become carpenters or anything else, it is quite another thing, and much less certain to be beneficial, to train a number of lads in the fanciful, as well as other routine of gardening, with the object of making them professional gardeners.

We have frequently said that the natural increase of gardeners, resulting from the employment of youths as may be wanted, will always be more than equal to the demand; and the more that are raised by special means, and these more likely than not inadequate, the greater the number of men called gardeners must eventually be who are unable to find employment—even at a lower average wage rate than that of bricklayers' labourers.

As to gardeners aping mechanics in their "Unions" for increasing wages and reducing hours of work, the idea is fatuous. Remuneration for skilled labour or any other is in the last resort governed by supply and demand, and so long as there are ten men for one vacancy money spent on "Unions," for placing the odd nine in comfortable positions, would be worst than wasted. This "Unionist" idea for the purpose indicated affords a fertile theme for verdant pens, and we have thrown as much rubbish written on the subject into the waste paper basket as would, if printed, fill several numbers of the *Journal of Horticulture*.

Gardeners' mutual improvement associations stand on an altogether higher plane, and the officials of these might, advisably and laudably, endeavour to assist those of their members of high character and capacity into situations which they would creditably fill. If no mistakes in judgment were made in such recommendations, those associations might in time be regarded as trusted sources

of supply of the right men for filling vacancies in the respective districts. We happen to know that last week a well written letter, by the chairman of one of those associations, was not without effect in gaining for a member a favourable hearing as applicant for a coveted position beyond the district in which the association is established. A letter from a "Union" of the other chimerical kind, would, there is little doubt, have been summarily rejected.

Our ardent young men who, with the best intentions, would flounder about in the Press, if Editors would allow them, in the advocacy of "Unions" for "altering things," do not appear to know that the plan has been tried. They seem to be in blissful ignorance of a smart secretary drawing 2d. a week from between 200 and 300 men employed in gardens near London for preaching to them when he could, writing to the Press (but not printed), and to individuals (uselessly), also in other ways fooling his "clients." But though these facts are not known to the present would-be "leaders" in a crusade, they will not perhaps be surprised to hear that the "secretary" was too fully engaged to do any work for two years. All he did during that time was to draw £300 in "tuppences," and as the payers were not a penny the better, the "Union" was "wound up," and the wide-awake secretary is probably living on his wits in some other congenial occupation.]

EPACRIS.

ALTHOUGH these very beautiful hardwooded plants are at the present time, like *Ericas*, under a cloud, I feel sure that they will again become popular and be largely grown. Their culture is by no means difficult, and when well grown they supply beautiful cut blooms during January and February—months when flowers are scarcer than at any other season. When cut with long slender stems few flowers can equal them for giving lightness to cut flower arrangements. Hybridists have succeeded in raising new varieties which, in point of showiness, are far in advance of older ones, and with further efforts in that direction we may confidently anticipate that still better results will be obtained.

Epacris are not only useful for supplying cut flowers, but are of great service for use as pot plants too. I have a vivid recollection of the important part they played in some ball-room decorations I assisted to carry out in my younger days. The plants were irregularly disposed among groups formed in recesses in front of the orchestra and along the sides of a corridor. They were set in a groundwork of Ferns and foliaged plants, Hyacinths, Tulips and Primulas being also interspersed between them, with large Palms waving their arching leaves overhead. Yet among the many beautiful plants used in these arrangements the Epacris were certainly the most conspicuous when seen under artificial light; their long slender shoots gave the necessary touch of lightness, combined with delicate colouring.

Those who contemplate making a start at Epacris growing will do well to purchase a few small plants, for although they are not difficult to raise from cuttings, the process takes a long time; too long, in fact, for these hurrying days, when speedy results are looked for. My advice in the matter is, obtain a few dozens of plants at once, and when these have been grown into shapely little specimens, make a point of inserting a few cuttings each year; the stock is thus gradually increased, and vigorous youngsters are always ready to take the places of any that go wrong, as some assuredly will do, under the best of management.

Young plants in 3-inch pots, if obtained now, will be ready for a shift into 5-inch ones. Good fibrous brown peat, similar to that advocated for *Ericas* on page 303, with sharp sand added, forms the best potting compost. Ample drainage must be given, and firm potting practised, to insure satisfactory results. After potting, place in some structure where a gentle heat is maintained, syringe lightly

during bright weather several times daily, and shade for a few hours. The aim should be to secure long and strong shoots; it is better to have a few of such than numbers of weaker ones. Watering must be carefully performed, but when it is done give enough to moisten the old ball throughout. This cannot always be accomplished in one application. A good waterer will attend to the driest plants first, and then give each a second application as the work of examining the whole stock proceeds.

When the young shoots have grown a few inches in length gradually admit more air, and during June provide all the air possible night and day, except when high winds prevail. Early in July place the plants in a sunny position in the open air, plunging the pots to about two-thirds their depth in ashes. This full exposure will have the effect of thoroughly ripening the wood, a most important point in connection with Epacris culture, for without well ripened wood shoots wreathed with flowers cannot be obtained.

About the middle of September remove the plants to their winter quarters; a greenhouse or other cool structure, from which frost is just excluded, is a suitable position for them, so is an early vinery in which the laterals have been shortened to admit light. If a few plants are wanted in flower during January, by the end of November place some of them in a house where a temperature of from 50° to 60° is maintained, with a suitable amount of moisture. Unlike *Ericas*, Epacris will bear a little gentle forcing. Plants kept in quite cool houses will form a succession. After flowering, the erect growing varieties require hard pruning, cut them back to within one or two eyes of their base, place in gentle heat, and when the young shoots are from 1 to 2 inches in length, shift into larger pots, and treat according to directions previously given for guidance during the growing season. A few pendulous growing varieties never make very strong shoots; in their case little pruning is needed; it only amounts to shortening a few of the longer shoots to preserve the balance of growth.

The following are all excellent varieties: *miniata splendens* (fig. 79), *exoniensis*, *Exquisite*, *Fireball*, *hyacinthiflora*, *h. alba*, *h. candidissima*, *h. carminata*, *Lady Alice Peel*, *Lucifer*, *densiflora elegans* (fig. 80), *grandiflora*, *rubra superba*, and *Viscountess Hill*.—PLANTSMAN.

P.S.—On page 304, a few lines from the end of my article on *Ericas*, I see a slight error has crept in; "*water* constantly at critical times," should read *watch* constantly, &c.

PEACHES.

IN penning the paragraph mentioned by "H. D." on page 294, I had no thought of binding myself to the magical six; I spoke of Barrington and Crimson Galande as if included in a general collection. Furthermore, I explicitly said my remarks were in reference to outside culture only. "Speak as you find" is a golden rule, and so I referred to Barrington as being a free and generous bearer. I have heard of the fault of defective stoning before; the remedy of applying lime need not be peculiar to this variety alone; all Peaches need lime. I have no hesitation in replying to "H. D." anent Crimson Galande. My experience of the variety in question, in totally different soils, on a south-eastern aspect as well as a southern, in more than one locality, leads me to say that I should certainly recommend Crimson Galande for outdoor culture in any district I know in preference to Royal George.—KITCHEN GARDENER.

— STREET TREES AND PATENT PAVEMENTS.—It is to be expected that everyone in planting trees will exercise the usual care to see that drainage conditions are satisfactory; but when the street pavement and side walk are asphalt or other patent material, unusual care is necessary, says "Meehan's Monthly," to have not only good underdrainage, but also good conditions above for the encouragement of moisture. A hole 1 foot in diameter is insufficient if cut directly through the pavement, as both air and water must pass through for the support of the tree. Two feet width is better, and 6 inches more will be acceptable; and if the surface be depressed towards the tree, to attract rain water, so much the better. Add a top mulch of hay or strawy manure, and the conditions will be improved. A layer of well-rotted manure placed just above but not next to the roots will hold moisture, at the same time giving food to the roots. Brick pavements are not as objectionable to trees, as there are many openings to admit the elements needed.

EPACRIS ELEGANS.

SEASONABLE NOTES ON FIGS.

THE earliest forced trees in pots yield excellent fruit during April and early in May. When the very early varieties, such as Early Violet, St. John, and Angélique, are cleared of their first crop the trees should be well syringed, the top-dressing renewed, and copious supplies of liquid manure be given to induce the second crop fruit to swell freely. If the fruit is very abundant it should be thinned, leaving a moderate crop only of the best at the base of the growths. The watering at the roots will still require to be moderate for Brown Turkey, Pingo de Mel, and White Marseilles, now affording ripe fruit; but still afford the supplies necessary to keep the foliage in health, and damp the floors and walls occasionally to prevent too arid an atmosphere.

For the colouring and ripening process a circulation of warm air is necessary, leaving the top ventilators open a little at night. This is essential to the fruit attaining perfection in colour and high quality. When the first crop of fruit is gathered commence syringing the trees twice a day, also watering copiously at the roots with liquid manure. Apply a top-dressing of lumpy material, so as to encourage active feeders, and enable the trees to make a more satisfactory second growth. If the fruits in the second crop show very abundantly they must be thinned, as before advised for the very early varieties, so as not to overburden the trees, to the prejudice of next year's bearing.

Planted-out trees in the house started at the new year will soon give indications of the first crop ripening, and from that time until the crop is perfected a little ventilation should be allowed constantly at the top of the house, and when the weather is favourable a free circulation of warm rather dry air must be afforded. Syringing should cease directly or slightly in advance of the fruit commencing to ripen, and though moderate air moisture is essential to the health of the foliage, a superabundance about the house must be avoided. Let the fruit be perfectly ripe before gathering for home use; if it has to be packed, it should be gathered a few days earlier. A good watering should be given when indications of ripening appear, which more particularly applies to trees with only limited space for the roots.

In succession houses attention will have to be given to stopping the shoots at the fifth or sixth leaf. Avoid overcrowding the growth, as the fruitfulness of Fig trees depends greatly on the exposure of the foliage and wood to plenty of light and air, and too much pinching and a superfluity of spurs is not desirable, as the finest fruit is borne on extensions. The successional growths also should be kept rather thin, allowing those only to remain that will be required to supplant the branches annually. Cut out and maintain a proper successional supply of bearing parts. It is no use, however, striving to render gross trees fruitful by stopping and thinning, for nothing will do that but judicious root-pruning and limiting the rooting area, rendering it firm, so that the trees live thriftily. Attend to syringing the trees twice daily, and water abundantly at the roots as often as required; employ weak tepid liquid manure, especially where the borders are small, and add to the mulching so as to keep about an inch thickness of lumpy material on the border into which the roots will spread, and this can then be fed to any extent.—GROWER.

ROYAL HORTICULTURAL SOCIETY.

SCIENTIFIC COMMITTEE.—Present: Dr. M. T. Masters (in the chair); Mr. H. Self Leonard, Rev. W. Wilks, Mr. Elwes, and Rev. G. Henslow, Hon. Sec.

Alpine Auriculas, mildewed.—A plant was received from Rev. C. Wolley-Dod infected by a fungus. It was forwarded to Dr. W. G. Smith for examination.

Apple wood, discoloured.—Some specimens received from Mr. Basham, were also sent to Dr. Smith.

Germination of Daphne Mezereum.—Mr. Elwes described some curious differences between the germination of some seeds of this shrub, in that the plumule grew up normally above ground, while in others, from some unaccountable cause, it appeared to be arrested for a long period before appearing, although they sent down roots underground in the usual way.

Hyacinth stem and leaves growing downwards.—Mr. Henslow showed a plant, the bulb of which had been accidentally inserted upside down. The roots had grown normally downwards; but the shoot, instead of turning upwards towards the light, had also grown vertically downwards. It subsequently elevated the bulb into the air, removing all the roots from the soil, and continued to grow solely at the expense of the nourishment contained in the bulb. The flower stalk closely invested by the leaves, was 7 inches in length.

Carnations attacked by Acarus.—Mr. Michael reported upon the specimens sent to the last meeting as follows:—"The Carnation pest is a Tarsonymus. All this genus are destructive and difficult to eradicate in consequence of their leaf and stalk-mining habits."

Diseased Carnations.—Dr. W. G. Smith, Leeds, reports as follows:—"On the Carnations sent none of the fungi usually present were found—e.g., rust, leaf spot, fairy ring spot. The symptoms presented are those of the disease known as 'bacteriosis.' This is the name given by Arthur and Bolley (Purdue Uni. Agric. Exp. Station, Bulletin 59, 1896), because they ascribed the disease to the action of a Bacterium (B. dianthi). They were able to infect healthy plants with cultures from diseased. A Belgian investigator, Paul Nypels, published in 1898 ('Notes Pathologiques') some observations on the disease, which point to some other agent than bacteria as the primary cause. Other workers

also hold this view. The disease is well known, and very destructive in indoor cultivation of Carnations in United States and in Belgium. The conditions favourable to it are overcrowding, defective ventilation, and the effect of moisture on the foliage, due to overhead watering. Prevention is evident, except for the last item mentioned; but overhead watering must be reduced as much as possible. The structure of the Carnation leaf indicates a plant suited to a dry open situation, like our native Dianthus, on rocks, old walls, and open pastures. In indoor cultivation means must be adopted to prevent too frequent watering of the foliage. This has been done by some growers in America, as described by Arthur and Bolley. Pieces of wire netting bent into a A shape are placed between the rows of plants, so as to keep the lower leaves clear of the stages. The watering is done by a hose directed into the A, and the water is distributed to the roots by a nozzle, delivering on both sides. Arthur and Bolley give illustrations in paper sent hitherto. The method has been successful against this and other diseases of indoor Carnations. Where this disease has already shown itself, it may be checked by spraying the foliage with Bordeaux mixture."

Vines malformed.—Mr. G. Wythes of Syon House sent branches of Vines with malformed flowering branches, supposed to be due to fog; but they presented a not uncommon condition of being tendrils bearing abortive buds. As Darwin pointed out, Vine tendrils are homologous with flowering shoots, and such transitional states between pure tendrils and bud-bearing ones occur on all Vines, and have nothing to do with external climatic conditions.

Effect of Lightning on an Oak.—A specimen received from Dr. Plowright of Lynn showed how oak wood is sometimes torn into longitudinal fibres by electricity. "The trunk from which this specimen was taken was that of a tree grown in East Anglia, and purchased for timber by a timber merchant in King's Lynn, from whose woodyard it was obtained. The amount of injury was comparatively slight, consisting only of a groove cut from top to bottom of the trunk, about 2 inches wide, and extending only a very short distance into the woody tissues, but tearing them up longitudinally into strips several feet in length."

Witches' Broom on a Scotch Fir.—This was received from Dr. Plowright, who writes:—"The specimen is sent by Hamon L'Estrange, Esq., and was found growing upon one of the Fir trees in his park at Hunstanton Hall, Norfolk. It consists of a mass of hypertrophied 'dormant buds,' measuring a meter in circumference round its widest part, and weighs 2½ kilogrammes. It is borne upon a branch which shows eight annular rings and springs from a lateral shoot. It is interesting to observe that this shoot is itself hypertrophied, as compared with the corresponding one on the opposite side of the branch, but that this hypertrophy only extends as far as the 'growth, beyond which it is atrophied and dead. The growth itself consists of seven or eight rounded masses, composed of aborted shoots—partial developed buds closely aggregated. The masses are of varying ages, some bearing green leaves, while others are quite dry and dead." The origin is supposed to be due to the attack of a phytophaga.

Malformed bulbous plants.—A quantity of decayed and arrested bulbous plants were received, both from St. John's Wood Cemetery of Marylebone and from Lincoln's Inn Fields. Both cases illustrated the effect of premature growth from the very mild winter, followed by severe check during the week of frost, and subsequently by excessive wet. Mr. Henslow observed that on the high ground and clay soil of Holland Park bulbs have come up exceedingly well, having been planted in September.

Apple trees affected by grubs.—Specimens received from the Chiswick Gardens were referred to Mr. McLachlan, who has reported as follows:—"The larvæ in the Apple twigs is no doubt that of Laverna vinolentella, which was formerly considered a variety of L. atra (the larva of which feeds on the fruit of Hawthorn) but is now regarded as distinct. I am not aware that it has ever been found sufficiently common to occasion serious damage, but as the egg is, no doubt, laid in or on a bud, and the depredation primarily confined to the bud, it is evident that the question of serious damage is only one of degree."

Odontoglossum Alexandræ.—Dr. Masters exhibited a spray on which every flower had three stamens instead of one only. It was received from Mr. Cookson.

Jatropha podagrica.—This scarlet-flowered species was awarded a botanical certificate. It is a well-known plant in botanical gardens.

A VICAR'S FRUIT PROTECTOR.

VARIOUS devices have been resorted to for preserving ripening and ripe fruits from injury by birds, wasps, flies, earwigs, and all such enemies that are so frequently troublesome and often ruinous; but we have not seen one so neat, and at the same time so substantial, as a sample that has been sent to us from Ashburton by the Rev. E. Darnley Smith.

This gentleman appears to have been engaged for a considerable time in developing an idea, which he reasonably hopes will bear fruit for himself—i.e., prove a success as a commercial article, and save fruit uninjured—we can scarcely yet say unspotted—for growers and exhibitors. If the article succeeds in one object it will in the other, and we shall be pleased if it do so in both.

It is new in material, design, and application. The material is perforated celluloid, light, durable, and inodorous. The design is that of the fruits to be protected. The one before us is of the shape of a fine Williams' Bon Chrétien Pear, which it would enclose without bruising, and bid defiance to such foes as those named tasting the fruit. For

Apples, Peaches, Plums, Grapes, and other fruits to be caged with equal security the forms would differ accordingly.

For purposes of application the protector is in two parts, each with a flange, and when the halves meet the flanges are gripped with an attached movable clip, and provision is made for the stalk of the fruit—it can be caged in a moment. So can many flowers, but though we should not like to aver that the incursion of “foreign” pollen would be prevented, slugs, earwigs, woodlice, and such like despoilers would be baffled in their attempts to take the best bits off the best blooms, and thus putting them outside the charmed circle of prizewinners.

That the new protector will do all we have suggested we have not a doubt, but there is one other thing it may or may not do, and it is just the possibility of its doing it that would have led us, if present, to have voted with the Fruit Committee of the R.H.S., that though the Vicar’s protector, or rather the protector of other people’s fruit and flowers, “may prove to be the fulfilment of a long felt want, it must be tested at Chiswick before any definite award can be made.” Our reason for supporting such decision is that an opportunity might be afforded for noting the effect of the encasements on the colour of the fruit. If this is not impaired in any way, the value of the protectors will be enhanced.

No doubt the material—celluloid—suggests inflammability, but so do gauze bags if placed in proximity to the fire. But this is not the place where protectors are used, and neither one nor the other will “go off” spontaneously. If the inventor can manufacture his unique appliances so as to sell them cheaply and keep them well before the public we shall not be surprised if they command a large sale. The invention is patented in Great Britain, and in process of being similarly protected on the Continent.

NATIONAL AURICULA SOCIETY.

THE accounts which I had received from various growers as to the condition of their collections did not lead me to form very exalted notions of what I should find at the Drill Hall on this occasion; more especially were the reports from the north of a gloomy character. My friend the Rev. F. D. Horner wrote to me a few days before the show, “Not only have I not a single truss in flower but not even a pip open,” and I knew, of course, that this involved most probably all the northern growers; but I certainly was not prepared to find that Mr. C. Turner, of Slough, was not able to put in an appearance, and it is, I think, the first time that I have ever missed him at an Auricula Show; yet withal one was a little surprised to find so many stands staged. They were not, of course, comparable in numbers to those of former years, and many of the flowers bore the mark of having been subjected to more warmth than the Auricula likes to have.

There were, however, some superb flowers shown. Mr. J. Douglas, of Great Bookham, had an even and refined collection, exhibiting no trace of coarseness; especially noticeable was a beautiful plant of George Lightbody, possessing all the good qualities of that grand flower. There were some other fair blooms also, such as Mrs. Potts, which still holds its place (notwithstanding one or two defects) among the selfs. Amongst the flowers exhibited by Mr. C. Phillips was a beautiful bloom of Mrs. Henwood, a new green edge, which was also exhibited in other collections. It is a flower of superior quality, the pip being very round and flat, the edge a bright green, and the body colour dark and solid. This flower has a curious history. It was raised from a pod of seed sent to the late Mr. Samuel Barlow by Ben Simonite; it was at one time nearly lost, but the plants were sent to Mr. Henwood, under whose fostering care it struggled back to life; and the fact that it is now shown by several exhibitors makes one hope that it will soon come generally into cultivation. The Rev. F. D. Horner, as usual, was frequently shown, and here, too, its good constitution makes it a general favourite. How different from Prince of Greens, which we may have for years without getting any increase. Mrs. Phillips and Ruby are both very beautiful selfs; and although we have such fine flowers as Heroine and Mrs. Potts, there is still room for others in this charming class. There was a sharp competition for the premier prize, which was ultimately carried off by the fine green edge to which I have already alluded—Mrs. Henwood, that old-established favourite George Lightbody running it very closely.

I have always maintained that the Auricula world sustained a great loss by the premature death of Mr. Woodhead, and I think this is more and more evidenced every year. He was but a short time at the work of raising seedlings, and he only sent out four—Black Bess, Rachel, George Rudd, and Mrs. Dodwell; and looking through the lists of successful flowers at any of our exhibitions, I find that these always take a leading position, and this year has proved no exception to the rule. They were in several of the winning stands, while in the competition for single plants, grey edges, the three first prizes were awarded for two of these flowers, Rachel and George Rudd, and I am sure it must be a great satisfaction to Miss Woodhead to know that the flowers still maintain their position. I find among the prizewinners the names of many new flowers. In Mr. Douglas’ collection there is Abbé Listz, a very beautiful green edge; Lady Churchill, Cleopatra, James Hanniford, another good green. In Mr. Phillips’ stand there were also Mrs. Phillips, a fine self, and Miss Barnett. Beside these there was, as already said, Ruby, a very bright self.

It would be ungenerous before closing these few notes not to say how much exhibitors and Auricula lovers in general are indebted to Mr. Henwood for the care he has taken in advancing the interests of the Society, and for the way in which the plants were put up for the Judges on the present occasion. Of course his labours were considerably

lightened by the thinness of the exhibition, but one feels that the same quiet and business-like habit would have equally availed him had the exhibition been much larger.—D., Deal.

FORSYTHIAS.

OF the numerous hardy shrubs now flowering at Kew, the above mentioned are, without doubt, the most attractive. At almost every turn the graceful, wand-like shoots of yellow flowers meet the eye. Here a group of *F. suspensa* 8 feet high perfectly covered with flowers, there a single plant of the same species rambling over some other bush, or again a bed of *viridissima* or *intermedia* dressed in gayest costume, all adding their share to form a really grand display.

Considering the uses to which these three plants can be put, especially the first mentioned, it is a wonder that they are not used a great deal more freely in gardens than they are at present. *F. suspensa* can be employed with almost equal success for a number of purposes. Trained over an old tree, fence, pillar, or other support, or planted in beds, it is equally at home, a difference in pruning being all that is necessary to make it fit the various places. The other species, *F. viridissima* and the hybrid, *F. intermedia*, are suitable only for beds or single bushes.

To cultivate they are very easy. Cuttings put in about July root in a very short time, and a year in nursery quarters is sufficient to make good plants for planting out. Any pruning should be done as soon as the flowers are over. When *F. suspensa* is grown in beds it is a good plan to cut the plants back fairly hard, as young strong shoots are then made, 4 to 6 feet long, which bear an abundant supply of flowers.—W. D.

THE ROYAL GARDENERS’ ORPHAN FUND.

AFTER “A. D.’s” letter on page 302 of your issue of 13th April, I trust that your correspondents, “S., Yorks,” and “A Country Gardener” will be so good as to acknowledge that they did not understand the working of this Society, or the amount of work done by our Secretary. Let me ask “S., Yorks,” and “A Country Gardener” if they know of any Society doing the same amount of good that the R.G.O.F. is doing at, say, double the expense? In the town in which I live are two or three orphanages, with a staff of attendants to look after their inmates. What about the salaries of these attendants and the sums spent for the upkeep of the buildings in which they live? Must it not be that these heavy expenses are borne by the subscriptions, which were meant for the maintenance of poor orphans? One hundred guineas would not go far in meeting these heavy outgoings.

But the R.G.O.F. leaves the fatherless ones with their natural protectors; amongst their own kith and kin; and spends nothing on bricks and mortar; and excepting the Secretary’s modest salary, nothing for administration at all; but each farthing given so generously is spent so wisely, that every subscriber can rejoice in the sound financial position of the Fund, and the great benefits it is conferring on those who need and participate in it. I would recommend “S., Yorks,” and “A. C. G.” to note the letter preceding theirs, on page 257. That shows that some gardeners do take an interest in the Society and its noble work. Mr. Cummins makes the excellent suggestion that the “boxes” should be worked more. I carried one at our Horticultural Shows and netted £7 11s. 6d. One of my boys did the same, and collected £5, before he was eight years old, and has thus become a life member. A younger brother now carries the “box,” which has already nearly £4 standing to its credit. I mention these facts to show what can be done if one tries. A little done this way is worth pages of carping criticisms.

I wonder what excuse could have been made for non-subscribing if the Secretary had not been paid, which, as “A. D.” reminds us, has not always been the case? Our late Secretary, Mr. Barron, carried on the secretarial duties for some years without fee or reward of any kind, until the Committee thought the financial state of the Society allowed some small sum to be paid for these onerous duties, and after submitting the proposal to the subscribers at the annual meeting. I for one voted for it.

With such a body of business men as we have at the head of the R.G.O.F. I do not think those gardeners who do subscribe to its funds need trouble, but may rest assured that all monies are put to the very best use—viz., to maintain poor fatherless children in their own homes. Not one farthing is wasted or misapplied. It is heart-breaking that cold water should be thrown on such charitable work, especially by non-subscribers. The Royal Gardeners’ Orphan Fund is a power for good, and does its work nobly.—ANOTHER COUNTRY GARDENER.

FILBERT CULTURE IN ITALY.—It will surprise many to hear that in certain districts of Italy the Filbert crop rivals the produce of the Vine in commercial importance. These delicious Nuts are grown on bushes or shrubs, which are arranged in groups that are from 15 to 25 feet apart, so as to insure the access of plenty of light and air. They thrive best in a deep clayey soil, and the planting takes place during November and December, of slips from the mother plant. The bushes do not bear fruit until the third year. They are periodically pruned, when any slips which have failed to sprout are removed and replaced by others; so that there are plantations which remain in full growth, although nearly a hundred years old. The Filbert is not subject to the diseases common to other crops, but it suffers severely from hailstones and from cold winds.—(“Indian Gardening.”)

FORCED CHERRIES.

I OFTEN wonder why Cherry houses are not common in gardens. The trees are easily grown in pots in any light airy structure, with sufficient hot-water pipes to maintain a temperature of 50° to 55° in the severest weather, and they need not be kept under glass for more than half the year. When started at the New Year, such fine varieties as Early Rivers, Belle d'Orleans, Empress Eugénie, and Governor Wood afford a supply of welcome and delicious fruit in May and June without much forcing. After the fruit has been cleared off the trees they can be placed outdoors, plunging the pots in ashes in an open situation, and duly attended to for water, and keeping the foliage clean, will be in excellent condition for forcing again, the fruit ripening somewhat earlier in the second than first year of forcing. The house will thus be at liberty for producing a crop of Cucumbers, Melons, or Tomatoes, as may be desired, and two crops had from the structure in one season.

Thus the culture of trees in pots has an advantage over that of the planted-out system. Still trees can be grown very successfully when planted in borders, and for early work these should be wholly inside, and neither too wide nor too deep. A border two-thirds the width of that of the trellis, 18 inches depth of soil and a foot of drainage, the top 6 inches of chalk or old mortar rubbish, answers well. Cordons 2 feet apart quickly cover the trellis, which should be about a foot from the glass. The roof-lights of planted-out Cherry houses should be movable, and provision must be made for ample ventilation, also due regard had to efficient heating, for Cherries cannot endure a close atmosphere or heat radiated at a high temperature.

Whether the trees are in pots or planted in the borders, the fruit of those started at the new year will be ripening. On the first indications of this the fruit must be kept dry, but the house should have atmospheric moisture furnished by damping the surface of the borders and paths occasionally. Admit air constantly, or condensation will take place, and moisture being deposited on the fruit, it will be ruined by cracking, and instead of having an agreeable, be given an unpleasant flavour. This is a main point in growing Cherries under glass. Another is not to allow the trees to suffer from dryness at the roots, but the soil be kept in a moist condition, an examination being made daily of trees in pots, and those in borders periodically, and whenever a supply is needed afford it thoroughly without delay.

Trees in pots require the leading growths pinched at about the sixth leaf and side growths at the third joint. Those on trellises must have the shoots tied in as they advance in growth, leaving no more than are necessary for furnishing the trellis regularly, allowing sufficient space for the spurs, and top those not required for training in at about the fifth leaf, pinching subsequent growths to one leaf.

The house should be freely ventilated on all favourable occasions, and when the external conditions are unfavourable recourse must be had to the heating apparatus to insure a circulation of warm, moderately dry air. Netting will be required over the ventilators to prevent the birds attacking the Cherries. Black aphides must be kept under by dipping the shoots or leaves in tobacco water. This pest soon spoils the fruit, therefore keep a sharp look out and destroy the first and every one seen.—YORKSHIREMAN.

THE YOUNG GARDENERS' DOMAIN.

NEW ZEALAND SPINACH.

SPINACH is one of the most useful green vegetables that we have, and is in great demand during the summer and autumn months. But in hot dry weather there is often a difficulty in maintaining a constant supply of good succulent leaves from the ordinary variety, owing to the plants running to seed ere they have attained any size. New Zealand Spinach will prove a splendid substitute, and though not so good in quality, it is less trouble to grow and far more remunerative. Being a native of a warmer clime than ours, it requires a warm and sheltered spot when planted out. Our *modus operandi* is as follows.

We sow our seeds in April in an ordinary seed pan, and place in a hotbed till germination takes place, when they are removed to a vinery shelf close to the glass, in a night temperature of 55°. As soon as the seedlings are large enough to handle, they are placed three round the sides of 48-pots, using ordinary loam as a compost, and allow them to remain in the vinery; when they have recovered from the slight check they are transferred to a cold frame to receive another shift into a 24-pot later. Keeping the plants three in a pot, we grow half a dozen pots in this manner, picking out the three best for a prepared border, the others we plant amongst the Gooseberry bushes to take their chance. This Spinach is of a spreading habit, therefore it must have ample space. Our most suitable place for planting is a wide border facing south, with a rich compost, making up three mounds, 4 feet apart, each composed of one barrowload of well decayed stable manure to one of garden soil; by so doing the roots are kept much warmer than when planted on the flat.

We consider it less trouble to grow the plants in pots, and give the shelter of a cold frame, planting in June, than to plant out earlier and incur the risk of cold winds and rain, which would lead to extra trouble in covering, besides giving the plant a severe check. By protecting the Spinach with mats in the autumn we have had a good supply up to the middle of November.—PARVO.

THE GOOSEBERRY.

AMONGST the many different fruits which are at present grown Gooseberries take a very prominent place, as they are always useful either for dessert or culinary purposes. The best system to adopt

in making a new plantation is to obtain from some of the leading nurserymen young trees of good sorts, the names of which are hardly worth mentioning, as there are so many from which to choose. Obtain trees with long stems, for if the branches are very close to the ground many of the fruits are spoilt, and it is difficult to do the necessary cleaning amongst the bushes during the summer. Previous to planting the ground should be well manured and deeply dug at the end of autumn, so that the early frosts can get into it. November is the best time for planting, or as soon as the weather permits. The distance between the rows should not be less than 5 feet, but if young trees are being planted they may be placed 2 feet apart in the rows, so that when they have grown and are touching each other, every other one can be lifted and planted afresh. In planting do not bury the roots too deeply.

It is advisable during the winter and early spring to sprinkle a little lime over the trees occasionally to prevent the birds from destroying the buds, and it is best done after a shower of rain. The pruning should be left until the beginning of February, as it can then be seen what to cut out, but if newly planted they will require little pruning, merely shortening the longest growths. Gooseberries are lovers of air and light, so when pruning old trees the centres should be kept perfectly open.

During the summer, if the weather is very hot, it will be found beneficial if some light manure is placed between the rows to prevent evaporation. If the trees have a heavy crop of fruit on them it will be necessary to thin them if large fruits are required. It may be done when they are about the size of peas, or a little larger, as they will then be useful for cooking. The fruits for dessert will require netting when they commence to ripen to keep birds from them, as these pests are very destructive. I may say, if fresh plantations are made the space between the rows can be utilised for such plants as Cauliflower, Cabbage, or any of the Borecoles; a single row will be sufficient.—P. R.

HARDY FRUIT GARDEN.

Disbudding Fruit Trees.—All fruit trees which are cultivated on walls, and to some extent restricted trees in the open, especially young stock, require more or less disbudding or rubbing out superfluous shoots. The practice of disbudding is employed chiefly on Apricots, Peaches, and Nectarines, and it is to these trees that attention should be first directed.

Apricots.—These trees on walls must now be frequently examined, and all the useless and superfluous shoots carefully removed. Many of the growths of Apricots which cannot be tied or nailed in May, if well placed, be pinched to several leaves for forming spurs. It is not desirable, however, to encourage spurs in inconvenient places. Short stubby shoots do not require removal, as these are natural spurs, and will produce fruit. Longer growths pinched back to three leaves will eventually form artificial spurs of a fruiting character. There is the danger of originating too many and crowding the trees. The best placed of the current season's growths may be laid in freely but not thickly. The rest which are not wanted for any purpose may be cut out entirely. These details, if carried out gradually, will not distress the trees or check growth.

Peaches and Nectarines.—In commencing to disbud, deal with the upper parts of the trees first, rubbing or cutting out the ill-placed shoots and those next to the wall, which cannot possibly be of any use. Make a selection of the best shoots for retaining to eventually lay in. One must be at the base of the current bearing shoot, and another should extend above the fruit in order that the latter may have a due supply of nourishment. The formation of artificial spurs is not so freely adopted with Peaches and Nectarines, as the best fruit is produced on young wood, and it is usual for the whole crop to be produced on wood of this character. The most vigorous parts of the trees should be disbudded first, leaving the more weakly parts to strengthen for a time. Leave the shoots on the upper parts of the branches for extending, and the under sides clear. Strong, sappy growths are not desirable for retention, such invariably starting from dormant buds in the old wood. They indicate rather deep root action. The best way of dealing with them is to rub or cut them clean out.

Plums and Cherries.—Disbudding the growths on these fruits is chiefly confined to wall trees and young specimens in the course of formation. In all forms of training disbudding is largely of assistance in shaping the trees, and preventing an undue extension of wood and crowded shoots to develop in summer. A set of principal branches must be originated, and spur growths gradually formed upon them in front. During this process disbudding is useful in making a proper selection, and it is obvious that when the spurs are older there will be a number of growths early requiring removal. For instance, ill-placed shoots develop behind branches and spurs. These must be rubbed or cut out as soon as possible. Growths that are well placed may be too numerous, in which case a selection must be made of the best, and it will require a certain amount of firmness to avoid retaining too many. When there are ample principal and secondary growths the strong sappy growths, or robbers, starting from various parts of the trees, should be early reduced or removed.

The treatment of the Morello section of Cherries is similar in every respect to Peaches and Nectarines. Fruit is freely produced on young growths of the previous year, and the aim of the grower must be directed to securing a good selection of medium-sized growths to lay-in for the succeeding year. The best for this purpose can only be resolved upon by proper examination, but it will be found that one, or not more than two, as near the base of the current bearing shoot as possible, are the best. A combination of spurs and young shoots for laying-in is favoured in some cases, but there is little doubt that decidedly the best results are secured from the annual renewal.

Apples and Pears.—Disbudding in spring on many wall trees is more needed than practised. Old established trees are not only too much crowded with spurs, but are very much overloaded with growths from them, as well as new shoots from dormant buds. As, soon, therefore, as possible when growths push forth attention should be directed to the removal of any likely to be superfluous. Much good will result from this, giving the better growths more room. Young trees may be trained and regulated in any shape or form by judicious disbudding in the early stages. Much of the spray growth in standard trees might readily be reduced by rubbing it out when young, instead of allowing it to develop into long shoots which need cutting out. Cordon Apples and Pears should be specially attended to in the matter of disbudding, inasmuch as a fruitful condition is an important point. The errors of overcrowding are quickly apparent in this form of culture, therefore every endeavour ought to be made to induce the formation of good growths, and afford them every opportunity of maturing well.

FRUIT FORCING.

Cucumbers.—Plants in hot water heated pits or houses may be syringed with clear rain water twice a day, so that every part of the foliage may be kept free of red spider, but it must be done without damaging the leaves, which are brittle and easily injured. Plants in full bearing require liberal and frequent applications of liquid manure at a temperature about the same as the bed, but do not supply it so as to cause a soft growth. Avoid crowding and overcropping. Maintain a night temperature of 65° to 70°, and 70° to 75° by day artificially, and as the fire heat is lessened there will be less need of moisture, but this must be well sustained to insure healthy and clean growth in foliage and fruit. Attend to the necessary stopping, thinning, and tying of the shoots, maintaining a succession of fruitful growths.

Plants in pits and frames should be frequently seen to for the regulation of the growth, keeping them rather thin, stopped to one joint beyond the show of fruit, and removing bad leaves as they appear. A sprinkling at closing time will be sufficient for the plants, not allowing them to suffer for lack of moisture at the roots. Ventilate early, increase it with the heat, and close in the afternoon so as to maintain a good temperature well into the night. Attend to the linings, taking care to prevent rank steam getting into the frames or pits, and afford covering over the lights for some weeks longer, or until the weather becomes so warm that the night temperature of the frame does not fall below 65°.

Melons.—*Early Plants.*—Directly the fruit commences to ripen lessen the supply of water at the roots, but not so as to distress the plants, for if the foliage has been kept clean and the roots in good condition a second crop of fruit may be had. Atmospheric moisture should be withheld, and a circulation of dry warm air insured, increasing the temperature to 70° or 75° artificially, and 80° to 90° with sun heat. Cracked fruits are mostly produced by keeping the plants too dry during the swelling period, and by a close and moist atmosphere with too much water at the roots when ripening, which induces an excess of sap and consequent effort at growth. Cut the fruits before they are very ripe, keeping them on shelves in a warm house until they are in proper condition, or they may be removed to a fruit room for two or three days to become equally ripened all over.

Successional Plants.—Fertilise the blossoms when fully expanded, the atmosphere being kept rather drier and warmer, and ventilation attended to early, with a little constantly if there is danger of moisture condensing on the blossoms. Stop the shoots at the time the fertilisation is done one joint beyond the fruit. To insure a full crop have a number of fruits on different plants in the same stage of growth. Earth the plants with some rather strong and rich loam after the fruits begin to swell, ramming it firmly, placing a little fresh lime round the stem to prevent canker, and if it appear rub the quicklime well into the affected parts.

Plants swelling their fruits should be syringed freely in hot weather at about 3 P.M., or earlier if necessity arise for closing, damping the floor in the morning and in the evening, using liquid manure occasionally. Shade only to prevent flagging. Ventilate freely in favourable weather, commencing from 75° to 80°, increasing or decreasing it during the day as may be necessary, maintaining a day temperature of 80° to 85° or 90° with sun heat, closing between 80° and 85°. If red spider or white fly appear, cover the hot-water pipes with a thin wash of flowers of sulphur and skim milk, and for aphides and thrips fumigate on two or three successive evenings.

Train the growths of plants in pits and frames regularly, avoiding overcrowding, and when the blossoms appear, fertilise them about mid-day. Maintain a good bottom heat by linings, and admit a little air if there is danger to be apprehended from rank steam. Employ thick night coverings, as the nights are yet cold, but do not allow the covering to hang over the linings of fresh manure, and so injure the plants by introducing steam into the interior. Sow seeds for raising plants to put out in pits and frames as they become cleared of bedding plants, and pot the seedlings as they require it.

Peaches and Nectarines.—*Earliest Forced House.*—The very early varieties are now ripening, and the trees must not be syringed, but the border should not be allowed to become dry. As the fruit of the other varieties will not be ripe for some time yet, the atmosphere must be kept genial by sprinkling the borders and paths as they become dry, syringing the trees in the morning, and again when closing the houses. The night temperature may be kept at 65° to 70°, but 5° less, though it will retard the ripening, will not tax the energies of the trees so much as the higher temperatures. Leaving the ventilators slightly open constantly at the upper part of the house will be an advantage. In the daytime, 70° to 75° by artificial means, and 10° to 15° more with sun heat, will be suitable temperatures.

Trees Stoning the Fruit.—Do not hurry the trees undergoing this process, 60° to 65° at night is ample, and 70° to 75° by day, avoiding high night temperatures and sudden fluctuations. A little air left on at night will prevent the deposition of moisture on the foliage through the night to any serious extent; enlarge the openings when the sun acts on the house, yet, without lowering the temperature, which should advance with the increased power of the sun, and a corresponding increase of ventilation. Fumigation should, if possible, be avoided. It dries the atmosphere, and not infrequently cripples the foliage, when the fruit may from the check be seriously imperilled and fall. Early closing is an advantage, but it must not be done to the extent of undue excitement, nor continued until late, the temperature being allowed to fall with the declining sun. It is also advisable to allow a little extra latitude to the growth, but on no account permit foliage to be made that must afterwards be removed in large amounts. The growths should be secured in position as they advance.

Trees Swelling their Fruits.—The fruit swells rapidly in the early stages, and up to the commencement of the stoning process. The swelling of the fruits is materially assisted by the maintenance of a genial condition of the atmosphere and the means employed to secure a good root action, which is best effected by a judicious and gradual regulation of the growth by the process of disbudding and in thinning the fruits. These operations should be done carefully, the more vigorous the tree the greater the danger of the fruit being cast in stoning, and the evil is often aggravated by previously disbudding severely, which favours strong growth more than steady progress. Supply water thoroughly to inside borders when necessary, lay in the shoots so as to induce them to grow in the proper direction, allowing room in the ligatures for the swelling of the growths. After the fruit has stoned it takes the last swelling, when the shoots should be well tied down, but a moderate extension of growths will materially assist the fruit in swelling. Any leaves that shade the fruit should be drawn aside or shortened, and fruits on the under side of the trellis must be raised on pieces of laths across the wires.

THE BEE-KEEPER.

CLOSING THE ENTRANCE OF HIVES.

How long will bees live during the dull days of winter if the entrance is entirely closed? This is of interest to bee-keepers who reduce the entrance to their hives more than is really necessary. Not long ago a case in point came under our notice. In an apiary in which there were several strong colonies of bees which had a tendency for robbing last autumn, the entrances were reduced so that only one bee could pass through at a time. No further notice was taken of them until quite recently, when they were examined so as to ascertain if they required feeding. One can imagine the surprise of the bee-keeper who, on more than one occasion during the winter had tested them for weight, to find one of the heaviest hives, minus a live bee. All the bees were dead between the combs. They had evidently been dead for several weeks.

On examining the entrance it was found to be quite closed. The doors moved easily when touched, and had doubtless been closed accidentally by the wind. How long they had been in this condition it was impossible to say with any degree of certainty. We are inclined to think that bees would live for several weeks with the entrance quite closed if a low temperature prevailed the whole of the time, as the majority of hives are not made so close fitting in every part but that a little air could get in; but should the sun come out brightly and strike directly on the entrance it would excite the bees, and in their endeavour to get out they would soon become suffocated.

In the case alluded to we were enabled to examine the hive a few days after it was discovered. The dead bees were still clustered between the combs, and had evidently been suffocated. This should be a warning to bee-keepers to examine the entrance to their hives at least once a week throughout the winter. The accidental closing of the door would then not be followed with such serious results. There is much less danger of an accident of this kind when the entrance is left open its full width throughout the winter.

FEEDING STOCKS.

It is important that bees should be supplied with ample stores at all times. If they cannot obtain it naturally then it must be supplied

to them artificially. This is more apparent during the breeding season than at any other. Unless there is a regular supply of food provided the queen will not continue laying. Any bee-keeper may easily prove this fact, as where there are several colonies some will be much shorter of stores than others. The stock having ample stores, and headed by a young fertile queen, will at this season have several combs filled with brood. Another colony, which is short of food, will be weak, and there will probably be only a small patch of brood a couple of inches in diameter. The latter queen may be quite as good as the former, but she will not lay more eggs or raise more brood than there is food for.

A change will, however, come over the scene directly gentle feeding takes place. This is best done by giving half a pint of warm syrup in the evening—a small quantity given daily is much better than rapid feeding as practised in the autumn. Syrup for spring feeding may be made in the proportion of 1 lb. of sugar to one imperial pint of water. This should be boiled until the sugar is dissolved; it is then ready for use. A bottle feeder, over the mouth of which a piece of thin muslin has been strained, this will prevent the syrup escaping at a too rapid rate. The bottle should be inverted directly over the brood nest, and if a piece of perforated zinc is placed on the top of the frames it will prevent the bees escaping. The hole in the quilt need not be cut larger than the top of the bottle.—**AN ENGLISH BEE-KEEPER.**

TRADE CATALOGUES RECEIVED.

W. Clibran & Son, Altrincham.—*Plants.*

J. Veitch & Sons, Ltd., Chelsea.—*Plants and Nymphæas.*

Vipan & Headley, Leicester.—*Garden and Farm Appliances.*

•• All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," **8, ROSE HILL ROAD, WANDSWORTH, S.W.,** and **NOT** to 12, Mitre Court Chambers, Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *nom de plumes* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Brunfelsia eximia (*Inquirer*).—The *Brunfelsia* may be grown in a cool stove or warm greenhouse, but not in an ordinary greenhouse with the temperature at 45° or less in winter time. *B. grandiflora* is the hardiest species, and does excellently in an intermediate house. It is a native of Peru.

Spaces Round Fruit Trees (*O. F.*).—It would be much better to fill the spaces 12 inches wide round fruit trees with decayed manure than to plant in them summer-flowering plants or annuals. Of course, by giving liquid manure the plants would not materially prejudice the fruit trees, still they are better without than with the encumbrances.

Charcoal (*Scotland*).—This substance is not a fertiliser, though useful for many purposes, such as mixing with potting soil to keep it sweet, absorb ammonia, and in other respects act beneficially. Some growers use about one part to sixteen of potting soil for rendering the soil porous and facilitating drainage, and the roots of many plants cling to charcoal before anything else, such as Orchids. It absorbs carbonic acid and other gases, and some consider that they are yielded up to plants as required for nourishment.

Rondeletia (*Rogiera*) **brilliantissima** (*S.*).—It certainly requires an intermediate temperature, though we have had it very fine in a greenhouse where the temperature has ranged from 45° to 50° during the winter. The plant does best in a border, as upon making a good growth depends its producing fine panicles or corymbs of bloom.

Climbers for a lofty Conservatory (*J. E.*).—*Acacia Riceana*, *Bignonia jasminoides*, *Clematis indivisa lobata*, *Habrothamnus elegans*, *Passiflora Comte Nesselrode*, *P. Imperatrice*, *Tecoma Van-Volkemi*, *Solanum jasminiflorum floribundum*, *Plumbago capensis*, *Clianthus panicum magnificum*, and *Cotonea scandens variegata*. *Lapageria rosea* and *alba* are very fine, and require to be trained near the glass.

Are Peacocks Mischievous in a Garden (*Idem*).—Very, they are vegetarians with a strong appetite, and devour almost anything in the green stuff way. They kept us one season almost entirely without Peas, clearing them from the rows in the ground.

Shrubs for Poultry Run to Afford Shade (*W. H. T.*).—These we have seen succeeding, and apparently liked by the poultry, were—Common and Purple-leaved Hazel, Common and Golden Elder, Blackthorn or Sloe, Common and Scarlet Dogwood, Common and White Lilac, Evergreen and Oval-leaved Privet, Common and Variegated Holly, Flowering Currant, and Cotoneaster Simmonsi. In large spaces we have noticed fowls fond of dusting under *Cupressus Lawsoni*, Hemlock Spruce, and English Yew.

Fruit Trees for Ornament (*F. D.*).—We do not know of any pamphlet on this subject. The planting of Apples, Plums, Medlars, Quinces, Siberian Crabs, and other fruits, has been several times advocated in the *Journal of Horticulture*, but if the articles could be traced the numbers containing them would probably be out of print. We scarcely think you need any guidance on the subject, as your letter indicates that you are fully aware that beauty with utility may be combined in many gardens by planting fruit trees judiciously in association with other ornamental trees and shrubs.

Dog's-tooth Violet not Succeeding (*Aprille*).—This bulbous plant does not succeed well on heavy clay soil, especially when very cold and damp. But why not take out a foot depth of the "clayey foundation," place in that depth of rubble, and on this a foot thickness of good soil, say a mixture of equal parts of loam and peat? Of course it is no use making a pit to hold water, as that in the clay would be without a drain to carry off the superfluous water. The best time for replanting is immediately after the leaves die away, inserting the bulbs about 3 inches deep. It may be grown in pots in a cold frame, removing to the greenhouse when in flower.

Apple from Old Tree (*E. G.*).—The fruit is the Wanstall (Wanstall Jack, Jack-in-the-Wood) a dessert Apple of the first quality, which "originated at Green Street, near Sittingbourne in Kent, with a tailor of the name of Wanstall about the beginning of the present century."—(Dr. Hogg's "Fruit Manual.") It is very handsome, skin golden-yellow on the shaded side, but red, which is striped and mottled with darker red on the side next the sun, roundish, but narrowing towards the eye, giving a conical appearance. Flesh yellow, firm, crisp, juicy, rich sugary, and highly flavoured. It is, as you say, very hard when first gathered, and will keep till May and June.

Establishing a "Mistletoe Farm" (*Worcester*).—We have only seen one orchard made to grow Mistletoe. It was an old one, and the Mistletoe berries were simply placed or burst on the smooth parts of the branches, especially those of an inch or two in diameter, and on the under side of them in patches of two or three at a yard distance along them, placing the seeds an inch apart. By bursting the berries on the bark the seeds adhere fast enough. There is no need to make incisions and squeeze the berries into them. Mistletoe always commands a market, but it goes through so many hands that the growers receive the least share. In ten years the Mistletoe would be grown sufficiently to bring in a fair return. We have had good "boughs" at seven years.

Hard Substance at the Eye of Figs (*G. K.*).—The hardness is caused by a fungus, the "spot," *Gloeosporium fructigenum*, which is perhaps induced by moisture settling at the eye, and giving the parasite a nidus. The best thing we have found was to use a little sulphur on the hot-water pipes, and admit air day and night. The circulation of air prevents the deposition of moisture on the fruit. Unfortunately the finer the fruit the more they are liable to attack, and that means that the structure requires to be kept drier and warmer, and more airy. We have also found a dressing of air-slaked chalk lime useful, applying a pound per square yard, and pointing-in lightly. There does not appear to be any imperfect fertilisation of the flowers at the upper part of the fruit.

Ants and Flowering Melons (*Wabara*).—You say that "ants are eating the essential organs clean out of the flowers" of your Melons. We have known a similar case. If you cannot prevent the ants ascending the stems by destroying the marauders, sponges dipped in treacle and water and placed among the plants will act as counter-baits, and lure many of the little pests to their doom if the sponges taken possession of are dipped in boiling water. If their nests or haunts can be found, a correspondent some time ago stated that a mixture of one part XL All insecticide and fifteen parts water poured in or among them will quickly reduce their numbers. A solution of camphor made by dissolving a lump the size of a walnut in a gallon of boiling water destroys those it reaches and tends to keep the others at a distance. Lumps of camphor placed about their runs is said to be a good deterrent, though we have not tried the plan. Perhaps some of our correspondents may describe methods of extermination that they have found effective.

Inga Seed (J. C. S.).—There are several species of Inga that are grown for their seed in the warmer parts of South America, principally of Guiana and Brazil, some being used for one purpose and some for another. That you allude to is probably the produce of *Inga vera*, chiefly used as a purgative. It is a native of the West Indies. There are several species with poisonous seeds, but Inga seed is that named, and causes dysentery in fowls.

Staphylea colchica and Lilac Marie Lagrange after Flowering (Idem).—They will flower again, only place them outdoors in an open situation after they have been properly hardened, attending to them for water, keeping clean in foliage, and supplying liquid manure occasionally; or plant them out in the open ground as soon as they have been hardened off and the weather becomes mild, where they will recuperate, and be available again after a year or two for flowering in the greenhouse.

Warts on Vine Leaves (J. H.).—The small excrescences on the under side of the leaves are not caused by fungus, but extravasated sap, or sap forced out of its proper channels. It is induced in the case of healthy Vines, as yours appear to be, by too much moisture in the atmosphere and a fully too high night temperature, under which conditions the sap vessels are liable to be attenuated. It also arises from a contraction of the vessels, but we doubt if this is so in your case. With care in maintaining a healthy buoyant atmosphere you will have little to fear, though a dressing of lime to the border, making it white, and lightly pointing in, might be further advantageous. We have seen excellent Grapes follow many worse cases of warting than in the leaves you send.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (Z. D. R.).—Through misdirection your box was delayed, and the contents were quite dead on receipt. All specimens for identification, as well as letters relating to Editorial matters, should be addressed to the EDITOR, JOURNAL OF HORTICULTURE, 8, ROSE HILL ROAD, WANDSWORTH, LONDON. (T. C.).—Both specimens are forms of *Fritillaria meleagris*, commonly known as the Snake's Head Lily. (C. D.).—1, *Cœlogyne pandurata*; 2, *Dendrobium fimbriatum oculatum*; 3, *Cattleya Trianae delicata*. (B. P. S.).—1, *Primula rosea*; 2, *Scilla bifolia*. (J. H.).—1 and 3, species of *Metrosideros*, and this is all that can be said about them without flowers; 2, probably a *Justicia*, flowers required for positive identification; 4, one of the many forms of *Pteris tremula*; 5, *Phormium tenax variegatum*; 6, *Celsia arcturus*. The soft-leaved specimens were withered through not having been packed in fresh grass. See above instructions. For Vine leaves see another reply. (J. P.).—The specimen, which arrived fresh and bright through good packing, is *Celsia arcturus*. It is a native of Candia, and was introduced in 1780.

GARDENERS' CHARITABLE AND PROVIDENT INSTITUTIONS

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—*Secretary*, Mr. G. J. Ingram, 175, Victoria Street, S.W.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.—*Secretary*, Mr. W. Collins, 9, Martindale Road, Balham, London, S.W.

ROYAL GARDENERS' ORPHAN FUND.—*Secretary*, Mr. Brian Wynne.

MAY, 1823.

IN turning out an old box of books we came on a most interesting find—a shabby old number of “The Farmer’s Magazine,” published quarterly in Edinburgh, on bad paper, about sixty-four pages of matter, and sold for 3s. The motto on the cover runs thus—

Ye generous Britons venerate the plough,
And o’er your hills long with drawing vales
Let autumn spread her treasures to the sun.—Thomson.

Who reads Thomson now? Has he not gone the way of many other minor poets?

History repeats itself, we are told; and were some of the articles in this old magazine read aloud, they might easily be taken for extracts from the current number of the Royal Agricultural Society’s Journal. There is so much about prices and rents, before and after “the war.” What war is not mentioned? We suppose the minds of men were still full of the Continental troubles, which were only terminated by the complete defeat of Napoleon in 1815.

When we consider that at that date our National Debt reached £880,000,000, that bread was dear, that the harvest of 1817 was a failure, and that there was no line of fleet Atlantic greyhounds to bring us bread stuffs from America, we cannot wonder at the general distress. In 1799 and 1800 rents began to rise; provisions were dear. They went down in price, but the rents were not abated. Again, 1811 and 1812 there was a time of good prices, so that speculation in land became rife; fancy prices prevailed, and so the land made far more than its real value—i.e., that is taking the average prices for say, twenty-five years.

In 1823 there was an improvement in the price of farm produce, but not enough to indemnify the farmer, where rents had not been abated upon leases taken from 1808 to 1820. The wage bill was not a heavy one in 1823. In Scotland men from 1s. 2d. to 1s. 4d. per day, women 8d. to 10d.; in Cumberland 1s. per day, with food.

But even at these low wages we find many men were out of employment in Norfolk, where good Wheat was making up to 68s. per quarter. It appears that in the autumn of 1822 corn was low in price, but with the backward spring of 1823 and short supplies the

price rose rapidly. Farmers had sold their Barleys at 24s., only to buy back seed at 36s. per quarter. As the spring was late sowing was late also, and the ground in poor condition as a seed bed. It is strange to hear of Wheat exported to South America and the States, but the fact remains.

Even in 1823 some of the advanced men were trying experiments at extra pulverisation, by slicing the soil with coulter instead of resorting to repeated cross ploughing. Nothing beats a good mould, be it for field or garden. Permanent pasture sowed down with the Wheat crop was in vogue, and the remark is made that this practice is rapidly gaining ground among the best farmers—i.e., most advanced. A rise of 1½d. per lb. is heralded as of benefit to the grazier—for the corn farmer there is nothing but depression. Fat cattle were worth from 6s. to 7s. per stone. On the 3rd of May Potatoes were still to plant in Scotland, while the remainder of last year's crop were only worth from 8d. to 1s. per cwt. It must have required a good heart to set them again. Faith is a distinctive article in the farmer's creed.

At the end of April many farms in Berwick were yet to let. Several would not be let at all, but remain on the hands of the landlord. Of these estates, says the Journal, "they cannot well be turned to worse account." That is a sad reflection on the farming capabilities of the landlord or his agent.

Another writer advocates more attention to dairy work, asserting that the grain and other farm produce have gone down in price, yet butter and cheese have fairly held their own. He also calls attention to the excellent market there is for veal, giving as an instance that calves four to six weeks old fed entirely on milk have been sold from £3 10s. to £5 10s. Veal is always in demand, especially in a manufacturing district where money is plentiful.

The highways come in for a few remarks. We do not quite agree with them. The suggestion is that certain parishes should be grouped together, and expenses paid out of a common fund. That is all very well if, first, all the roads be put into what we may term "tenantable repair;" but we know a case in point where some roads were rated at 10d. in the £, and were grouped with roads in other parishes that were rated at 2s. 6d. in the £. It seems hard that those surveyors who have done their roads well should be made to bear the deficiencies of their less careful neighbours. Any road can be made good, provided the management is right—i.e., the best of granite, constant scraping, and intelligent road menders—and once made, a road need be of very little annual cost.

An Irishman asks a question we have never seen asked before—perhaps this is our ignorance. He wants a recipe for blackening stone walls for fruit trees, such as should be durable and economical. Will the Editor tell us the reason for this?

Other old writers are much agitated about bimetallism, only they do not call it by that name. Others, again, are worried about uniformity in weights and measures. We were much puzzled at a term constantly recurring—"per boll"—and we have not yet quite arrived at the proper definition.

[The old Irishman's object in blackening the wall was doubtless to make it warmer. A white surface reflects the sun's rays, a black surface absorbs them. If a thermometer with a clear bulb exposed to the sun indicates, say, 100°, the bulb, if blackened, will induce a rise of 10° or more very quickly. The reflection of intense light and heat from a white wall exposed to hot sun thus acting on the under sides of the leaves is not conducive to the healthy growth of plants growing against such wall, while black surfaces may be too hot for a time in certain positions, though they are generally preferable to white, if either of the two extremes must be chosen. Seeds germinate more quickly during early spring in very dark than in very light-coloured soils, and hoeing among early Cabbages expedites growth in spring, because the darker upturned particles absorb more of the sun's warmth than does the more or less bleached and smooth surface.

As to the word "boll," the definition which "puzzled" our excellent coadjutor will probably have "arrived" before these lines

are printed. The word is derived from the old English *bolle* (Anglo-Saxon *bolla*), and means a bowl or vessel, and may be of wood, hence the line by Longfellow—

"Brought them *bolls* of food in basswood."

Basswood is wood of the American Lime tree (*Tilia americana*); but more to the point is the fact that "boll" was an old Scotch measure. For Wheat and Beans it contained 4 Winchester bushels; for Oats, Barley, and Potatoes, 6 bushels; a boll of meal, 130 lbs avoirdupois.

From "bowl" to "bowled" is a quick transition, as some of our cricketing friends will soon experience. We should be pained, however, to bowl out our talented farmer, or he might be constrained to throw Shakespeare at us:—

"Alas! I had rather be set thick i' the earth,
And *bowled* to death with *Turnips*."

WORK ON THE HOME FARM.

A few more samples of British weather! Since our last we had four days of continuous rain, followed by bright sunny days, but a night temperature reaching as low as 19° Fahr. The rain quite stopped all work on the land, as it would have been worse than useless to take horses upon it, so the animals have had a needed rest, and the men turned their hands to the yards, where there was a quantity of manure intended for Swedes in the home field. This has been all moved and thrown up into hill ready for carting out when required.

This labour will be repaid in the better condition of the manure for spreading, as well as in the preservation of ammonia through diminution of the heating process, so wasteful of it. Years ago, when artificials were less valued, and muck more so than nowadays, farmers made a general practice of turning over their manure heaps once at least, but often more. We seldom see men employed at such work now. We suppose that this is one of the things that has been dropped in the interests of economy, or perhaps in some cases because, though the money is there to pay them, men cannot be had to do anything more than is absolutely necessary.

Everywhere we hear complaints of scarcity of labour, and what is worse, of the utter incompetence of so much that is available. The smarter of the village youths either go into shops or obtain office work, whilst others get employment on the railways, or in the large manufacturing towns. Those left behind take little interest in farm work, though they are gaining a livelihood by it; they rather avoid becoming specially competent in any one branch, such as hedging, stacking, thatching, or sowing. Few of the old hands have not some line of work for which they are specially distinguished, but their sons do not care for such distinction. Every day, therefore, skilled hands become scarcer and command higher wages. Surely there should be sufficient encouragement then for a young labourer's ambition, when to a good wage he can add the healthy freedom of a country life.

[Hundreds of labourers are happier and more settled than are numbers of unfortunate gardeners.]

REMARKS.

16th.—Overcast, with occasional spots of rain early; sunny at midday; rainy from 3 P.M.
17th.—Fine and generally sunny day; spots of rain in evening.
18th.—Generally sunny, but rather hazy.
19th.—Mild sunny and spring-like day; clear night.
20th.—Bright early; sun visible through thin cloud in morning; cloudy afternoon.
21st.—Incessant rain from 4 A.M. to 4 P.M., and showers later.
22nd.—Fair early; sunny morning; overcast from 3 P.M.
With the exception of the 21st (which was a wretched day) a fine week, but cooler than any of the previous three—G. J. SYMONS.

BARR'S PURE GRASS SEEDS

For Lawns, Tennis Courts & Cricket Grounds.

The following mixtures are composed of PURE GRASS SEEDS only, which have been thoroughly cleaned and carefully mixed. They cannot fail to give the most satisfactory results.

We sell the seed by weight, which is the only correct method of estimating quantity needed for a given space.

BARR'S "THAMES EMBANKMENT" GRASS SEEDS for Parks.—A special mixture which has been found very successful in many public and private parks and squares around London and throughout the country. Per lb., 1/3; per 10lb., 10/6; per 20lb., 20/-.
BARR'S "STANDARD" GRASS SEEDS for Garden Lawns, Golf Links, Cricket Grounds, &c.—In this mixture there is a larger quantity of dwarf, fine-leaved Grasses than in Barr's "Thames Embankment." Per lb., 1/6; per 10lb., 12/6; per 20lb., 22/6.

BARR'S NEW MIXTURE OF DWARF GRASSES for producing an Extra Fine Smooth Lawn.—A special mixture of the finest-leaved and dwarfest-growing Grasses, producing an EXTRA FINE VELVETY TURF, and saving labour in not requiring frequent mowing. Per lb., 2/-; per 10lb., 18/-; per 20lb., 34/-.

Fuller particulars, with Hints on the Management of a Lawn, sent on application.

BARR'S NEW LAWN MANURE, "PHYTOBROMA," **WATSON'S LAWN SAND**, the best Weed Killer for use on Lawns. Full particulars on application.

BARR'S SEED GUIDE (free) contains a full Descriptive List of the best Vegetables and most beautiful Flowers, with many practical Hints on Culture, valuable to Gardeners, Amateurs, and Exhibitors.

BARR and SONS,
12 & 13 King Street, Covent Garden, London.
NURSERIES: LONG DITTON, SURREY.

BEGONIAS for 1899.

B. R. Davis's New Catalogue will be sent to all purchasers of this popular flower. A correct Descriptive List, with revised prices, of one of the largest and best collections in existence. Also

B. R. DAVIS'S NEW GARDEN ANNUAL.
For purchasers of first class, reliable Garden Seeds and Plants.

B. R. DAVIS,

BLACKBERRY CULTIVATION.

WHEN shall we see the Blackberry receive its place in gardens generally as worthy to take rank with the Raspberry and other bush fruits? I suppose the correct answer to my query is, When its true value is realised and its cultivation is understood.

It is now nearly twenty years since I planted my first row of that best of all Blackberries, the Parsley-leaved Blackberry, and I yet in a lively remembrance of its marvellous crop, in the third year from planting, of huge clusters of the large glossy fruit, and of the astonishment of everyone who thus saw cultivated Blackberries for the first time. The mere sight of it was sufficient to warrant the prediction of a great future for it, both in private gardens and for market, and this feeling gained force from a knowledge of the ease and certainty of its cultivation.

Yet even now one seldom sees it grown to perfection; if planted at all it is relegated to some out-of-the-way place among trees as an undergrowth, or to form a thicket, anywhere but in the garden among other fruit. The result is total or partial failure, yet a little thought must bring conviction that really fine fruit in abundance could not be so obtained. One might go farther and add that it is owing very much to want of thought and an intelligent grasp of possibilities, perchance also some degree of prejudice, that has hindered the extension of Blackberry cultivation.

A couple of rows of it in one of the Derbyshire County Council's fruit plots have induced much inquiry and discussion. One visitor actually asked how I could waste good land upon such rubbish, adding that the proper place for Blackberries was some out-of-the-way corner. Knowing that something tangible is the best answer to such queries, I have, in the last two years, had fruit plot demonstrations when the Blackberries were ripe. The sight of these two rows, each 20 feet in length, laden with nearly an hundredweight of ripe fruit, has induced something akin to excitement amongst our visitors. This, and one's

No. 2640.—VOL. C., OLD SERIES.

explanation of the few and simple details which go to render success a certainty, is doing good work.

But one has to remember that, however fully cultural details are explained, it is seldom that amateurs grasp the significance of every point; that which is clear enough to the trained gardener is too often vague and indefinite to them. When, where, and how to plant may be remembered; not so the fact that in order to obtain a heavy fruit crop there must be proportionate vigour of growth, and sufficient time for the plants to become well established in their permanent quarters. To impress this upon the minds of beginners there can be nothing like a well-established row in full bearing and full vigour of growth. By full bearing I mean a row of, say, 6 feet in height, laden thickly from bottom to top with fruit clusters from 9 inches to a foot in length; and by full vigour of growth, plenty of shoots 10 or 12 feet in length and nearly an inch in diameter. Such shoots are the growth of one season, not upon old wood, but directly from the stool or crown; they must be kept tied in as growth progresses or the rows will be unapproachable; and though tolerably free growth may be had in poor soils growth of full vigour and a full crop is only possible in fertile land.

Intersecting—not boundary—fences, might be turned to profitable account as supports for this fruit; the form of support is immaterial. An open situation, rich soil, the plants 4 feet apart, if in rows 6 feet between the rows. Cut down to two or three buds in planting. Cut in hard the growth of the first, and, if necessary, the second year. Stout fruiting wood will come freely either in the second or third year, according to the condition of the soil. This is a matter very much in the hands of the cultivator, and I have known more than one instance where feeble growth and small clusters of fruit has led to the Blackberries being uprooted and thrown aside in disgust. When the strong growth comes do not tie it upright to the supports, but rather aslant, so as to induce every lateral bud to break and develop fully its cluster of fruit. After the leaves are fallen in autumn the fruit wood is cut off close down to the stool, and the young wood tied in or regulated for the next year's crop.

I may add that I planted some of this Blackberry last November, and more of it in the present month. Both lots of plants came from the same nursery, those at the beginning of the season being fine examples of sturdy vigour, those at the end of the season being so small and feeble as to be hardly worth planting at all. If this may be taken as an indication that the demand has been so great that the stock was about exhausted, it goes to show that the cultivation of this fruit is receiving more attention than I supposed, and that its value is obtaining the general recognition it deserves.—E. L.

IXORAS.

My first acquaintance with Ixoras was in a lean-to Pine stove, the pots being plunged in the tan bed, and the structure heated by flues. That was in the year 1850, and the plants, mostly *I. coccinea*, were evidently at home. Since that time I have seen many as good in profusion of foliage, denseness of trusses, and brightness of flowers, but they have been the exception rather than the rule. I have often striven to grow Ixoras in stoves equal to those exhibited by Messrs. Baines, Letts, Cypher, and others, but could never approach their superb specimens. I have an idea that these plants require and must have bottom heat if the specimen is to be grown in the most creditable condition. In few places at the present time do stoves contain the old-fashioned fermenting beds, and this I think to be the sole reason that the plants are oftener seen in a fair rather than a splendid form.

The heat from hot-water pipes does not appear so congenial to them as that of fermenting materials, and they are liable to attacks of insects, such as scale, red spider, and sometimes mealy bug. I know some growers insist that plants are not benefited by ammonia in the atmosphere, but I find they thrive better where there is liquid manure in the evaporation troughs than where there is only water. That syringing or sprinkling with soft water induces better health in plants than even soft water, and that growth is always superior where there is a mulch of material constantly evolving ammonia.

I think it advisable to give the foregoing preamble, for anyone attempting to grow Ixoras in an ordinary stove may not have the success with them they desire, especially if the grower desire to compete at shows. The plants can be grown fairly well in the usual stove structures, but unless these can be kept at a high temperature and supplied with plenty of moisture when the plants are growing and preparing for flower, there is little worth growing Ixoras for. When

well grown, they are amongst the handsomest and gorgeous of stove-flowering plants, the foliage itself being by no means unattractive.

PROPAGATION.

Ixoras are readily propagated from cuttings. These should be of the half-ripened shoots—that is, short-jointed and moderately firm, inserted singly in small (2½-inch) pots, in sand over sandy peat, plunged in a close frame with a bottom heat of 80° to 85°, and kept shaded. The single-pot system is better than inserting at the sides of a larger pot and after rooting potting singly, but the plan has sometimes to be adopted in order to cover with a bell-glass. Roots will, as a rule, soon be emitted, when the young plants may be gradually inured to the air of the house, and placed in 5-inch pots.

SOIL.

The most suitable compost is fibrous sandy peat, with a little leaf mould or very old cow manure, about a fifth, and quite a sixth of sharp white sand. This is the old-fashioned compost, and there is not any better, though I have seen good plants grown in equal parts sandy, fibrous loam, and fibrous peat, with pieces of charcoal, broken pots or bricks, and sand. They grow well in fibrous peat. Good drainage is very important, and this should be secured with rough material; indeed, the compost ought to be rough for established plants, potting rather firmly.

TREATMENT.

If the plants placed in 5-inch pots are given plenty of heat and moisture they soon grow, and all the better if the pots are plunged in a bottom heat of 80°, or never more than 90° at the base of the pots. When the heat is from fermenting materials, the young plants succeed and grow freely, and a little shade from bright sunshine in summer time helps them wonderfully. In dull weather, however, and at all other seasons, the plants cannot have too much light. Therefore keep well up to the glass, or at least give ample room so that they may have light equally from above and sideways. Then they will grow sturdily, and naturally form a compact bushy plant with little training.

Some of the species and varieties flower in 5-inch pots, and are among the most effective flowering plants we have. Such plants are particularly fine for decorative purposes, and from lasting a long time in bloom are likely to be kept so long a time in the house as to be of little use afterwards. But even if they have to be thrown away after use in rooms, what is to hinder the keeping up of a stock of plants year by year? A sojourn of a few days in relatively cooler quarters than the plants require does not materially injure them, but care should be taken that the soil does not become soddened with water, as frequently happens with plants placed in vases.

For specimens, whether large or small, the young plants require pinching or pruning. If short-jointed cuttings are used for propagation the plants will mostly grow bushy enough for flowering in 5-inch pots without pinching, but when the young plants have a tendency to spindle they should be stopped when well rooted. It is an excellent plan to stop some, and allow others to grow without, so that they will form a succession. Some growers root cuttings in the spring, selecting young shoots of moderately soft wood, insert singly in small 2½-inch pots, and root in brisk heat in the propagating frame. The plants are given 4-inch pots when rooted, and allowed to grow and flower in them. They are very attractive, and should be grown on a much larger scale for purposes of decoration. If the young plants are needed for bushes, the point of the shoot must be removed when the cuttings are well rooted. The spring-rooted cuttings are supplemented by others inserted in late summer or early autumn, wintering them in the 2½-inch pots, and about the middle of February stopping and placing in 5-inch pots. Some that promise well are not stopped, and those that are not so promising are pinched. Thus there will be a succession in this case also, and with both autumn and spring plants in 4 and 5-inch pots.

The plants intended for growing into specimens should not be allowed to flower as it weakens them. In February, or earlier, they may be cut into shape, it being a good plan to cut back the whole of the shoots to insure an even break, and consequently an expansion of the trusses at one time, if they are allowed to flower, or an even development of growths. It is easy to remove the trusses of bloom early with scissors if the plants are not wanted to bloom. The point for specimens is to prune the plants vigorously in order that they may never get larger than bushes, and may send out lateral shoots enough to lay the foundation of a plant capable of producing ample trusses of bloom. As a consequence of this pruning they yearly generate an augmented supply of side shoots, which soon get so numerous that they hinder the leading ones from flowering finely. Those, then, should be examined, when the buds are on the point of expanding, and all except those which are intended to grow or flower, with such as are to remain for giving verdure and compactness to the plant, should be taken off entirely, more magnificent bunches of bloom would thus be unquestionably secured.—G. ABBEY.

(To be continued.)

CYPRIPEDIUM BELLATULUM HYBRIDS.

CYPRIPEDIUM Venubel, figured on page 315 of your issue of April 20th, is another addition to the list of hybrids in which *C. bellatulum* is one parent. It is astonishing what influence this parent bears on its offspring, as by the woodcut given it is easily seen that *C. Venubel* has a great likeness in form to some of the other crosses effected with this species. Never before have I heard of a *Cypripedium* producing six flowers on one spike, and I assume the spike is a fasciated one. Even then it must be an exception to the rule of *C. bellatulum* hybrids, as not all of them are of an extraordinarily vigorous growth.

Most people, I am sure, will admit that the hybridist has made immense strides in this class. Let us start with *C. Lawrebllum* and *southgatense*, the former a cross between *C. Lawrenceanum* and *C. bellatulum*, and the latter between the last named and the hybrid *C. Harrisianum*, both of which received F.C.C. from the R.H.S. in 1892. Then followed *C. Charles Rickman*, which resulted from *C. bellatulum* and a variety of *C. barbatum*, and was raised by the gardener whose name it bears, and since has been raised in other collections, and received varietal names, such as *Meteore*, *Marchioness of Salisbury*, and *Leysenianum*. It has received under its various names several recognitions, and no doubt each of the seedlings differs in some respect from the others. Another fine cross raised at Burford is *C. conco-Lawre*, which is a cross well expressed by its name. Then we have *C. Annie Measures*, a cross between *C. bellatulum* and *C. Dayanum*. *C. Arnoldæ* was shown by Messrs. F. Sander & Co. in the same year (1894), and both received F.C.C.

In the year following several very fine plants were first shown in which this species was a parent. First we have *C. Mrs. F. Hardy*, a cross with *superbiens*, which received an award of merit; and then *Gertrude Hollington*, a cross with *C. ciliolare*, which received the F.C.C. *C. Olenus* was first shown in 1895, and of which perhaps it may be said, this cross, the reverse of *C. Gertrude Hollington*, has produced the finest hybrid *Cypripedium* in cultivation, which was shown at the last Temple Show as *C. Olenus*, Burford variety; it received a F.C.C. on April 10th, 1898.

C. James Buckingham, a cross with a hybrid (*C. enfieldense*), raised in the collection of W. Hollington, Esq., of Enfield, received an A.M. in 1896. *C. Schofieldianum* followed, and is a cross with *C. hirsutissimum*, and received an A.M. in the same year. *C. Madeline* raised in the same collection as *C. Charles Rickman*, resulted from a cross with *C. Argus*, and also received an A.M. 1895. *C. Chapmani magnificum*, a cross with *C. Curtisi*, received a F.C.C., as did *C. conco-bellatulum*, which, as its name implies, is a cross with *C. concolor*. *C. bellatulo-vexillarium* received an A.M. when shown by Mrs. Briggs Bury of Accrington.

There are other existing hybrids raised from this species—namely, the lovely *C. Paris*, which is a cross with *C. Stonei*, *C. Meauriæ*, *C. William Lloyd* (fig. 81), which has a hybrid for a parent in *C. Swanianum*; then there is *C. Godefroyæ bellatulum*, shown by myself at the last Yorkshire Gala. It will be seen that the list of these interesting crosses is getting rather lengthy, but it is to be expected that, good as they are, there are even more beautiful ones to be flowered yet.

As is only to be expected with such crosses, they are extremely variable in growth, some being much more vigorous than others. All with which I have had to deal succeed in a warm *Cypripedium* house, elevated in one corner to themselves, potted in one part good fibrous peat and one part good yellow loam, mixed with some finely broken potsherds and a little living sphagnum moss. When they require moisture they are carefully dipped in a bucket of chilled soft water, taking care that water does not run into the base of the leaves, which is apt to cause decay, and for this reason they are never sprinkled. In the winter months they require small quantities of water, and none should be given unless the grower is quite satisfied that it is necessary. These and the *Cypripedium niveum* hybrids, which I may speak of at some future date, in my estimation, comprise the most beautiful of all *Cypripediums*.—J. BARKER, *Hessle*.

LÆLIA PURPURATA VERSICOLOR.

THIS is one of the finest of the *purpurata* varieties, the deep markings upon the petals giving it a very distinct and handsome appearance. It is greatly superior to such as *L. p. Ashworthiana*, in which the lip seems to be repeated in the petals. This beautiful variety seems also to be extremely free in growth, the owner of the original plant having taken several fine pieces off it, yet he tells me it is

breaking strongly again from the back buds this season, a fact that does not point to the ill effects of division.

EPIDENDRUM VARICOSUM.

This is a dwarf growing plant of rather peculiar habit, the pseudobulb lengthening out into a leafy stem, and producing erect spikes of flowers, these being small and of peculiar colour. The sepals and petals are brownish, lip white with rose purple spot, and the blossoms last well in good condition. A native of large tracts of country in Central America, *E. varicosum* is not a fastidious plant as to temperature, but does best in a light position at the cool end of the *Cattleya* house, potted in a rough mixture of peat fibre and moss. The plant is one of those that have received several names from different botanists, the variation in the colour of the lip doubtless accounting for much of the confusion which has occurred. It was first discovered by Mr. G. Ure Skinner in Guatemala, and probably sent by him to Mr. Bateman.

CATTLEYA CITRINA.

The delicate perfume of this Orchid, and the fact of the colour being very unusual in the genus, gives it quite a unique position. Its habit

FIG. 81.—CYPRIPEDIUM WILLIAM LLOYD.

of growing head downwards, too, is peculiar, and altogether it is one of the most distinct Orchids in cultivation. It is not everywhere a success, and most growers are under the necessity of purchasing newly imported plants occasionally to keep up a stock of it. It is most likely to succeed if wired to blocks of cork or rafts lightly dressed with sphagnum moss. Probably most of our Orchid readers have tried it in some way or other, and any who have been at all successful over a lengthened series of years, would render a service to others by recording their experience with it. Any note on the times of growth and rest, as observed under various conditions, would be exceptionally interesting, and also instructive to those who are trying to grow it with only moderate success.

MASDEVALLIA TRIARISTELLA.

This is one of the most beautiful of that charming section of the genus, comprising many lovely little gems—not at all showy, but by their marvellous structure and dainty beauty very interesting to those who find a place for other than showy Orchids. The plant is only about 3 inches high, the flower stems almost invisible, and each bearing a little brownish crimson and yellow flower, of so complicated a structure that a description of it conveys no idea to the lay mind of what it is really like.

The culture of this section requires a considerable amount of care, but there is no particular difficulty to be got over; all depends upon timely and judicious attention to the various small details. In the

first place, it is a native of purely alpine regions, where ample light is always present, and where the conditions do not vary so much winter and summer as in Britain. Thus in summer it is difficult, even by heavy shading, to keep them cool enough; in winter our dull sunless days are very distasteful, and we have to do the best possible by keeping the glass quite clean, and the plants well up to it. The usual Orchid compost of peat and moss suits it well, but obviously only a little is necessary for such small growing plants, the roots of which never push far from the centre of growth.—H. R. R.

THE STRAWBERRY.

FEW garden plants have been more improved by cross-breeding, selection, and by the application of suitable manures, than the Strawberry. It is probable also that more money may be made by the growth of Strawberries in the open air of this country than by any other kind of fruit. As much as £20 per acre profit has frequently been obtained, and when the best varieties have been cultivated, it is no exaggeration to say that an acre of this fruit will realise as much as £100. The forcing of Strawberries under glass has also within the past few years opened out an almost new, and certainly a profitable industry. The quantity of Strawberry fruit obtained per acre varies enormously, ranging from 75 bushels to 300 bushels, or possibly even more. This, however, will depend largely on the variety grown, and the treatment the plants receive. As no plant will repay careful culture more than the Strawberry, so, on the other hand, few plants deteriorate so quickly if they are neglected or improperly manured.

FOOD REQUIREMENTS OF THE STRAWBERRY.

In order to understand something of the food requirements of the Strawberry, it is desirable to study the chemical constituents of these plants, and the fruit they produce.

An acre of Strawberry plants of full growth, taken without the underground roots, would probably weigh about 8 tons. Of this 8 tons, about 6 tons would consist of water and 2 tons of dry substance.

A good yield of fruit would probably weigh 10,000 lbs. per acre; this quantity, owing to its succulence, would yield only half a ton of dry substance, the remainder being water.

To produce these amounts of dry substance in the Strawberry plants and in the fruit it is necessary that there be taken up from each acre of land during growth and development, say approximately, nitrogen 105 lbs., potash 110 lbs., lime 112 lbs., magnesia 17 lbs., phosphoric acid 41 lbs., silica 50 lbs., and soda 8 lbs. Other chemical elements will be imbibed also, but these latter we need not take into account, as they are usually provided in sufficient quantity by fertile soils.

As there will be five times more nitrogen taken up by the growth of an acre of Strawberry plants than there will be by an average yield of Strawberry fruit, it follows that in order to secure a full crop of fruit the plants must be brought into a vigorous and sturdy habit of growth for the purpose of assimilating the necessary quantity of carbon from the atmosphere for the building up of the fruit tissues, which has to be done very rapidly, as the fruiting period of the Strawberry is of short duration. Consequently large demands will be made upon the soil for immediately available forms of plant food, especially of the three elements—nitrogen, potash, and phosphoric acid. This is shown by the fact that 100 lbs. of the ashes of Strawberry plants will contain 26 lbs. of potash, 6 lbs. of phosphoric acid, and 1 lb. of soda; while 100 lbs. of the ashes of Strawberry fruit will contain from 40 to 50 lbs. of potash, from 14 to 16 lbs. of phosphoric acid, and from 8 to 10 lbs. of soda.

THE MANURING OF STRAWBERRIES.

A soil to be in a suitable condition for Strawberry culture as regards fertility, must contain a large excess of available plant food over and above the amount that can be utilised by the immediately growing crop, since it cannot be supposed that the roots will be able to absorb, by virtue of their disposition in the soil, more than a comparatively small proportion of the applied fertilising ingredients.

The old adage for Strawberry culture, "the more manure the larger the crop," may hold good on poor, hungry soils, but on sound rich loams, rank forcing manures, whether natural or artificial, should be employed with caution. If farmyard manure and rich vegetable compost are used in excess, or a large quantity of strong nitrogenous manures, such as nitrate of soda, or sulphate of ammonia, then abundance of leaves and vigorous runners rather than fruit will be the result.

A moderate dressing of farmyard manure thoroughly incorporated with the soil during the winter is doubtless a capital preparation for Strawberry culture, as this will keep the soil open, porous, and moisture-sustaining. But as the richest soils, even when assisted with farmyard manure, contain only small amounts of readily assimilable plant food, it follows that judicious applications of soluble

artificial manures may largely aid fruit production if these are applied in early spring before active growth has commenced.

Let old dead leaves and runners be removed from the plants and the ground cleared of weeds, then apply between the rows, not later than February, a dressing of soot, superphosphate, and potash salt in equal proportions, say from 3 to 6 cwt. per acre. This will be found to retard injurious effects from slugs, as well as feeding the plants, causing them to develop a sturdy, robust habit of growth, which is the best foundation for securing a full yield of the finest fruit.

FEEDING STRAWBERRIES IN POTS.

In the pot culture of Strawberries the plants are necessarily cramped in their root development, and, therefore, require special care in feeding. The benefit of good liquid manure when the fruit is setting becomes apparent. A solution containing half an ounce of superphosphate, half an ounce of potash salt, and quarter of an ounce of nitrate of soda to each gallon of water may be used. This manure must not be applied over the leaves and blooms.

A good liquid manure can be made by suspending a canvas bag containing sheep droppings and soot in a tank of water a few days before being required for use.—J. J. WILLIS, *Harpenden*.

PINCHING FRUIT TREES.

ON page 317, April 20th, Mr. Geo. Picker asks a pertinent question which growers will do well to carefully consider, though perhaps few will entirely agree with him. The practice of summer pinching fruit trees is a good one under certain circumstances, but I fear we are all too much inclined to carry it out in cases when there is really no occasion to do so.

My opinion is that summer pinching was first practised principally with the object of obtaining fruitful wood close to the main branches of trained trees, rather than in the belief that the wood would be brought into a fruitful condition earlier than by non-pinching. In the case of trained trees on walls or espaliers pinching is a necessity, in order to secure a well shaped tree and to keep the spurs near the main branches, but when such trees have been closely pinched for years improved results are obtained by removing alternate branches and laying in young shoots thinly wherever room can be found for them. In my view a good crop of fruit is of far more consequence than the precise training of branches.

Now let us turn to the consideration of bush and pyramidal trees. In their case I fail to see the slightest necessity for pinching, beyond that required to prevent shoots from becoming crowded, or checking the vigour of a "robber," except in the case of a cultivator who desires to grow as many varieties as possible in a limited space. By the aid of summer pinching and root-pruning this object is best accomplished, because unstopped trees require more room than closely pinched ones. This is indeed a vital point in connection with the matter. When asked for information on pruning generally, the advice I invariably give, Allow each tree plenty of space, and when a sufficient number of branches have been secured to lay the foundation of a well balanced tree, simply thin the shoots in summer to allow sun and air to act upon every leaf.

In regard to the point, Will pinching produce fruit buds on the current year's growth capable of producing large, healthy flowers? I say yes, in some instances, but only in case of varieties which make their growth early; with the majority of Apples and Pears two seasons elapse after pinching before fruit buds are formed.—H. DUNKIN.

MR. GEO. PICKER gives the Journal readers a question to answer on page 317, bearing on the influence of pinching of the summer growth in fruit trees. His opinion is that, to satisfactorily answer the question, a dozen Apple or Pear trees in variety, worked on the same kind of stock, should be planted with their roots near the surface, and in ground well prepared. This course would prove whether pinching would benefit the sorts under treatment; but it would not satisfactorily give a precedent for other varieties, because it has been proved so often that varieties differ materially in their fruit-bearing characters. A tree of a shy bearing Apple or Pear would not respond to any appreciable extent to the influence of pinching, and if the tree happened to be a vigorous one, pinching would result in lateral growth rather than the formation of fruit buds.

Pinching is useful in the case of trees that are unequal in strength of branch, by temporarily diverting the sap into the channels of those that are weaker. Except in such cases I do not think any material benefit would follow the general adoption of pinching of the summer growth of Pears and Apples. Vigorous trees, whether young or older established, after being subject to years of hard pruning, will often, if the lateral growths be thinned and the stronger ones left unshortened, change from barren into fruitful trees in a surprisingly short space of time. This I do not think would follow pinching.

Thinning of the weak and crowded lateral spray, so as to let the sun play on the stronger shoots to ripen them, will not only prove to be a less laborious undertaking, but result in fruitful branches. By this method the character of trees is changed. The only objection that can be taken to it is the branches, when roped with fruit, require to be supported, or they are dragged out of their natural position and form what are known as "sprawling" trees.

Mr. Picker is quite right in saying that many varieties will produce fruit buds on the current year's growth, when their roots are in good condition, without any stopping, but this happens with free bearing sorts, or those of greater age, that have been subjected to radical changes in the method of pruning. One has only to plant an equal number of Blenheim Pippin and Lane's Prince Albert Apples to prove the vastly divergent characters of the two. The last named will commence to fruit within two years of being planted, and continue to do so, provided the weather is right at the flowering time, while at the same time pinching of the summer growth will never make a Blenheim produce similar results from a young tree, no matter how expert a man might be in its manipulation, simply because its nature is opposed to early bearing.—W. S., *Wills*.

WHAT is the advantage of pinching fruit trees during their growing season if a greater weight of fruit can be obtained without? I have been deeply interested in fruit culture for many years. Our soil is very heavy, and if the Apple trees are left to take their chance, although carefully planted on land that is well drained, the foliage soon has a yellow unhealthy appearance, and the trees canker and die. These, I may say, were chiefly on the Crab stock.

A few years ago we determined to try experiments with other stocks. Messrs. Veitch recommended the broad-leaved Paradise stock; Mr. Rivers thought his Nonesuch stock would suit our land. We therefore tried both, and they have been an unqualified success. Two-year-old bushes were obtained; these were cut hard back when planted, and grew at a rapid rate the first season. The following autumn they were root-pruned; the shoots were thinned, and those remaining were slightly shortened back. The following summer all the varieties carried a heavy crop of fruit. These were thinned so as not to exhaust the trees. As a proof of the fine fruit they bore I may mention the fact that one fruit of Bramley's Seedling turned the scale at 23 ozs. Summer pinching has not been practised, neither has it been necessary to root-prune the trees since the second year.

The trees have cropped heavily each year since; last season, owing to the fine autumn, we had the heaviest crop of well coloured fruit we have ever grown. The trees have stakes placed round them to support the branches, otherwise they would break off owing to the weight of fruit. If such heavy crops of fruit can be grown without summer pinching, why carry out the operation?

The varieties comprise the following:—Lord Grosvenor, Bismarck, Lane's Prince Albert, Potts' Seedling, Stirling Castle, Bramley's Seedling, and Cox's Orange Pippin.—S., *Yorks*.

THE pinching of fruit tree shoots in my opinion is productive of fruit only in a secondary way. As a rule spurs, and therefore shoots, are so thickly placed on espalier, cordon and other trees, that, without pinching light and air cannot reach the basal leaves. If these individual shoots were thinly placed, as they are upon open free-trained trees and the leads of espaliers, all would form fruit buds, and eventually fruit spurs, without any pinching. It is the artificial method of training and pruning that makes pinching necessary, and I consider it is really necessary with vast numbers of fruit trees and bushes.

When growers wake up to the importance of disbudding their Apples and Pears, thereby keeping the shoots far thinner than they are kept at present, there will be less need of pinching; and in this connection it may be well to add, that in numberless cases that have come under my observation pinching has been productive of evil. In the first place the shoots are pinched too early, before the leaves are properly developed, and afterwards the lateral shoots that result from the pinching are allowed to grow into a thick mass, thereby excluding the light and air, and defeating the very end in view.

To be effective the pinching should go on as long as there is any fear of growth starting, taking each lateral at the second or third leaf, and as these have no direct bearing upon the spurs and wood that is to be retained, they may be pinched when quite soft, or when the leaves are half grown. Then, as Mr. Molynaux has pointed out, the trees may be pruned early, and the morning sun in autumn will reach every one of the principal leaves.

On this, in my opinion, the whole question turns. Anything that hinders the full development of the principal leaves—as early pinching undoubtedly does—or keeps the light from them, as under present system the let alone principle would do, is productive of harm. A well thought out system on the other hand of pinching at the right time when necessary, thinning, and allowing a little freedom where circumstances allow, will insure fruitful trees.—H. R. RICHARDS.

POTATO AND OTHER TRIALS IN SURREY.

I HAVE just completed the planting of the usual Potato trials on the four plots placed at the disposal of the Surrey County Council by various local bodies for the testing of the merits of some of the best varieties of vegetables. All these plots are in conjunction with large groups of allotments, and it is found that the growing of divers kinds and varieties of vegetables under such conditions, all being duly labelled very legibly, furnishes much more of interest in the county than can result when the trials take place in a central ground that may be difficult of access to those persons most immediately concerned.

Besides Potatoes, grown on all four plots, a fine selection of the best dwarf and 3 feet Peas have been sown on two, and on the other two there will be trials of about twelve of the very best Dwarf Kidney Beans obtainable, including some not yet in commerce, and also of Beets, including the best stocks procurable. These are all products which create great interest in allotment holders' minds, and to be able to see them growing and cropping under the best methods of culture that can be furnished renders the trials of exceeding value.

The earliest planting of Potatoes was at Richmond on April 14th. Here were planted on one-half the plot two rows each of comparatively early varieties. Duke of York, White Beauty of Hebron, Webber's White Beauty, Early Puritan, Pride of Tonbridge, The Rover, Beauty of Hebron, Sutton's Supreme, Lye's Victory, International, Devonian, Early Regent, Challenge, and Sutton's Reliance. All these should be ready to lift early in August. The Richmond soil is very early, and also light and porous. The allotment holders plant their Potatoes much sooner than April 14th, as very late ones suffer in hot dry weather.

A plot of 20 rods on the Surbiton group, whilst the soil is rather more retentive, it is yet somewhat sandy; but the position is colder, and generally crops are a fortnight later than at Richmond. Here were planted on April 15th single rows of generally stronger growers in Potatoes, including Syon House Prolific, Challenge, International, Teneriffe Kidney from imported tubers purchased to test against the Canary Islands, Ivo which obtained an award of merit at Chiswick. Devonian, also another A.M. variety; Pride of Tonbridge, early and a fine cropper; Sutton's Reliance, also a great cropper; Prime Minister, Chancellor, Conference, The Dean, these latter four of my own raising at Bedford; the famous Up-to-Date, Loveland's Kidney, a variety of great table excellence; Windsor Castle, Satisfaction, Renown, Quantity and Quality, Carter's Snowball, and Ellen Terry. This list comprises a very fine maincrop selection, and some of the best varieties in commerce. Besides these, are now growing fourteen rows of 3 feet Peas, a first-class selection that it would be hard to excel amongst midseason and late varieties. Kidney Beans and Beets will follow.

At Englefield Green, on what may be described as pure dark sand, all the ground has been by special request planted with Potatoes, including many varieties not known in the locality. In this case broad furrows were opened with a spade in the sand 30 inches apart, and native guano tried for the first time here. For this purpose two rows of fifteen varieties of Potatoes were planted, the first row in each case having a dressing of the guano, at the rate of about 12 lbs. per rod, the other row being undressed. The ground had no other form of dressing given it. It will be interesting to see later what may be the effect. Judging by the perfume emitted, the manure is rich in ammonia.

The other plot is in a very open, exposed, wind-swept field at Great Bookham; the base being chalk, and the soil rather poor. Here one half of a plot of 25 rods has been sown with Peas, and the other half planted with Potatoes. In this case varieties have been chosen as suitable for the production of seed tubers for the hundreds of continuation school gardens in the country. This plot also adjoins a large group of allotments.

Dwarf Beans and Beets will be sown about the second week in May, as that is quite soon enough for exposed aspects. The Beets include the Sutton Globe, Sutton's stocks of Del's Crimson, Blood Red, Cheltenham Greentop, and Nutting's Dwarf Red, also Dropmore Selected, Pragnell's Exhibition, Webb's Satisfaction, Carter's St. Osyth, and Perfection, and one or two others sufficient to secure a very useful trial, as all are of the best stocks. In the manner above indicated a goodly number of selected varieties of useful vegetables are brought under the notice of hundreds of workers who watch their growth from beginning to end. Thus the very class of men who most need it obtain information in the quickest and most practical manner possible, also of the exact kind that is of the greatest service to them, and are not slow in turning it to useful account. They learn far more in a season or two from these simple object lessons than they could learn in ten years from the reading of elaborate reports.—A. D.

BEAUTY IN NATURE AND ART.

DAFFODILS waving in the west wind—Daffodils galore. Lusty Sir Watkins, noble Emperors, fair Empresses gave a right royal greeting as we trundled our wheel up to the garden home. Three and twenty miles in the teeth of the same west wind accounted for over three of those precious hours, which mean so much in a day at Straffan. But as the most toilsome journey oft brings the most pleasing retrospect, so perhaps one enjoys the more the quiet delights of this picturesque place. There was nothing prettier seen than a broad patch of the old English Daffodil, *N. pseudo-Narcissus*, studding a portion of the lawn; but large quantities of the elegant princeps made a brave display in a similar position. The latter have seeded freely, and numerous progeny surround patches of the parent plants. Occasionally a bunch of rush-like stems show where the seed pod has burst without scattering. This is naturalisation pure and simple, and intensely satisfying to those who love the "Lilies of Lent."

It is worth remarking that only on the grass has the production of seedlings been in evidence. Probably this part of the lawn being mossy forms a congenial bed for germination. Sir Watkin is boldly assertive, the produce of nine bulbs, originally, being numbered by thousands, or appeared to be so. These are offsets, obtained in the planting and replanting of the beds, which have long since escaped the bonds of orthodoxy, and grow and blow at their own sweet will on the grass. Would that stately maximus were as prolific. We see a dozen or so of its deep golden blooms among the peculiarly narrow twisted foliage; the one here is the fine form known as the College Garden maximus. On the far bank of the Liffey Daffodils brighten the scene, and some have crossed the frontiers into the pastures beyond, where they are scrupulously avoided by the grazing stock.

By a suspension bridge "The Island" is reached, and here freedom reigns. Graceful Bamboos bend to the breeze, and are well represented by such kinds as *nitida*, *nigra*, *viridis-glaucescens*, *palmata*, and *japonica* (Metake), all being pictures of health and happiness. The position as regards soil is a moist one, and Mr. Bedford says that on higher and drier ground they never did well. Leaf mould, with a liberal allowance of sharp sand, is the medium they revel in. An infant *Gunnera manicata* is pushing its way like a young Hercules through the protective covering of last year's foliage, and it is notable that beyond affording some compost to the choicer plants when introduced to the Island, Nature is, practically, allowed to have her fling; hence there is no tidying up or trimming down of dead leaves and withered stems. Down the reaches of the river red Willows are very fine, but, strange to say, the golden one does not succeed at Straffan.

Reluctantly leaving the Island for a turn through the kitchen garden, a youthful Bedford in knickerbockers is seen violently gesticulating at the end of a long walk. The wireless telegraphy spells out D.I.N.N.E.R, for which inestimable benefit to hungry horticulturists one, at least, would, if he could, make "The Missus" a V.M.H. on the spot. There is no more interesting thing in Straffan than the low wall in front of Mr. Bedford's house. It was a happy thought of the Bedford boys when they decked it with Alpines. It has been noticed before, but never did it appear so much a thing of beauty and interest as it did to-day.

In the greenhouse, chiefly devoted to plants in bloom, there is "nothing to see." The "nothing" consists of as bright and varied a show of bloom as the house will hold, including a number of superb examples of the old Machel Mignonette. From the roof of a warmer house hang pendant panicles of the quaintly pretty *Hexacentris mysorensis*. The orangery holds some noble trees in fruit and blossom, and some coveted Kentias enjoy the subdued light, flourishing in such small pots as are dear to the heart of the decorator. Orchids are, as they always are, well to the front at Straffan. The famous *Wardianums* are on the wane, but still beautiful; one deep tinted variety is very conspicuous.

With all that is rich and rare under glass, however, the outside appears to have especial attractions to-day. The improving hand is so much in evidence over a score of years, and we would fain do likewise in our own sphere of operations recently migrated to. In a sheltered glade is a collection of Japanese Maples, cunningly contrived to catch the eye as one passes them, on a shrubby walk at right angles. A good effect is created in some beds of herbaceous *Pæonies* by clumps of Daffodils informally disposed through them; the purple-red springing foliage of the one, and the golden blooms of the other, being almost daring in its tone amid the faintly discernible greenery of tree and bush; and what an aggressive thing is the hybrid Briar, *Anne of Gierstein*! Up some barely visible support it has climbed fully 15 feet, and must when in bloom be a pillar of beauty.

But the day declines and our "wheel" awaits; the miles are many, and thorns lurk by the wayside. It is, however, an easy run back, for the wheel and the river are both making for the sea, until the Phoenix Park is reached, where there is no choice but to join a long procession of jaunting cars returning from Fairyhouse races. Poor fairies! how those jaunty jarvies rattle their bones over the stones as we descend

into dear, dusty Dublin! Through the city, out on the Rock Road, no rocks ahead now save a limb of the law who looks suspiciously as we dismount staggering with stiffness, but braced with pleasant memories of Straffan.—K., *Dublin*.

P.S.—Some Irish notes recently intimated that changes might occur at Straffan consequent on the death of its honoured master. Such is the case, and the Hon. Mrs. Barton, whose devotion to gardening has so widely developed its beauty and interest, is about to reside at Luttrellstown Castle, fortunately within touch of her old home, whilst Mr. Bedford remains on the scene of those labours of love which have been unremittingly carried on by him for over twenty-three years.—K.

EXPERIMENTAL HORTICULTURE.—3.

ESTABLISHING EXPERIMENTAL STATIONS.

FROM what has already been said it will be judged that there is ample room for the foundation of experimental gardens and stations. The more they can be increased in numbers, especially if they be established on anything like a uniform system, the greater the gain to cultivation and the nation. Experimental work, as regards plant life and horticulture, may be summarised under three heads.

1, Scientific research. This would deal with the more abstruse problems of plant life, structural and physiological variations affected by different treatment, the causes of varying manurial actions in different soils, and all the laboratory work concerned in the analysis of soils and products.

2, Practical work. Directed to the elucidation or improvement of ordinary horticultural operations. This series should also include experiments intended to advance the cultivator's knowledge of manures, and their most profitable applications. The important matters of insect destruction, and disease prevention or cure, would likewise demand attention.

3, Commercial aspects. Under this head the experimentalist would be concerned in the endeavour to—A, Economise the cost of production; B, Increase the productiveness of land; C, Improve the plants grown.

A complete experimental station should include the three series of investigations, but where that is not possible valuable work can be done in either of the others provided it be commenced and carried out on a carefully considered plan. Instances are known to me where from defects in the original design or in the subsequent execution, years of labour and great expense have been rendered comparatively useless. When there are so few attempts at research this is especially deplorable, because it serves to deter others, and throws an unmerited odium upon scientific work. The essential points to be determined at starting are:—

- 1, The objects of research.
- 2, A systematic plan of work.
- 3, The method of recording.

These are mutually dependant, and a defect in either will very seriously affect the final value of the work. Without a definite object in view it is impossible to form a satisfactory plan; in the absence of a judiciously organised system the best work will be of little avail; and, lastly, failing an accurate and well-devised method of recording results, the whole becomes profitless, disappointing, and even misleading.

These preliminaries being settled, the next considerations are the conditions under which the experiments are to be conducted. If it is intended to deal with cultivation in the open, the selection of land becomes a matter of the first importance. The site should be preferably one that is not unduly exposed to extremes of temperature, wind, or rainfall. The soil of the area to be cultivated should be as nearly equal in character as possible, and beyond this it is desirable to have some knowledge of previous treatment and cropping, especially when this has varied in different parts of the selected land, as it may often throw a light on the seemingly erratic behaviour of subsequent crops. In most cases an equalising influence is exerted by placing the whole of the land under one kind of crop previous to commencing experimental work. Rough or foul land may be planted with Potatoes as a good preparation, provided the soil be not deficient in potash, and a suitable dressing of artificial manure be applied, the exact composition of which is known. If the land be poor in nitrogen a crop of some leguminous plant could be sown and turned in.

Samples of the soil for analysis should be taken from different depths, and where the land appears to vary in character it may be necessary to select several spots in the same field. At most first-class stations it is usual to take samples of the soil at three depths, the first, second, and third 9 inches, the total depth thus tested being 27 inches. For the majority of crops with which horticulturists are concerned this is sufficient.

Apart from the cropping already mentioned, the actual mechanical preparation of the soil is a matter of some moment. For farm crops ploughing is always adopted, but for horticultural work digging or

trenching is needed, and this becomes an expensive item. At the Woburn Fruit Farm the whole of the land was trenched, and the greater part was forked afterwards, this being rendered necessary by the abundance of "twitch" and other weeds. Such a treatment is beneficial and desirable, but on heavy soil it entails a preliminary cost of over £20 per acre—an example of the expense attendant upon thoroughly organised experimental work.

It is of great importance to also have a set of meteorological instruments, and to keep continuous records of temperature and rainfall. A valuable instrument in connection with these observations is a sunshine recorder, as the actual amount of sunshine to which vegetation may be exposed has a material influence on the behaviour of plants. Besides the ordinary instruments in the cases at the regulation height above the ground, it is also needful to have radiation thermometers on the ground, and exposed to the sun, so that the extremes of temperature may be registered, while a thermometer in the soil will often furnish interesting data.

The general regulations of the work will depend upon its nature and objects, but a few points are worth keeping in mind, because they are applicable to both large and small undertakings. All operations where comparisons are to be instituted between the crops should be performed as nearly as possible at the same time, and under similar conditions as regards temperature and moisture. This applies to soil preparations, planting, seed sowing, and taking the crops for records.

Where artificial or natural manures are employed it is desirable to continue the application of one kind to the same plot of land over as long a period as possible, as the introduction of fresh compounds when there may be much of that previously employed already in the soil may lead to very conflicting results. Where trials of manures are conducted upon neighbouring plots, as it is important they should be, it is necessary to have a clear space between the adjoining plots, as the more soluble manures are readily diffused through the soil, and would thus militate against the accuracy of the results.

As large a number of plants of one kind should be subjected to the same experimental treatment as possible; the risk of error is reduced in proportion, and the value of the records increased. Very misleading opinions may be formed from observations confined to a small number of individuals.

There are many other matters apparently small which demand attention in experimental work, but these are some of the chief, and I have referred to them because throughout their careers horticulturists are essentially experimentalists in some degree. They are usually men whose powers of observation have been developed by the very nature of their calling. It is seldom, however, that the funds at their disposal or the demands for the results of their skill and labour will permit systematic research; consequently their observations are not often recorded, unless it be in the pages of the horticultural press, or they remain in their own notebooks, where they may prove of value to the owner for future reference, but are lost to the great body of workers. All the same, horticulturists should use notebooks freely, constantly, and systematically; every man, whether beginning or advanced in his occupation, would do well to review each day's work and difficulties, and place on record his impressions or observations for future reference. It is important, however, not only to note results, but to accurately record the conditions under which they have been obtained. Much judgment and close attention are needed in this to avoid erroneous conclusions. A mind that is peculiarly free from bias or prejudice is essential in recording experimental results, and the ignoring or exaggeration of apparently slight details will seriously influence the conclusions. Truth should be the sole object of the experimenter, even though it be contrary to preconceived ideas.—R. LEWIS CASTLE.

AUTUMN-SOWN PEAS.

THE practice of sowing Peas in autumn is not nearly so often carried out as formerly; indeed it is only occasionally that one finds cases where it is done at all. The greater accommodation afforded by pits, heated or cold, which cheap glass furnish in the present day, does away to a large extent with the necessity and risk of autumn sowing.

Last autumn I made a sowing on a sheltered border as a chance or probable catch crop, and for a time everything went well with the plants, and to some visitors unaccustomed to find thriving Pea rows in winter they proved interesting, and raised many speculations as to the ultimate result. The severe spell of wintry weather that followed the abnormally mild and wet period proved too much for them, notwithstanding that they were protected at night with evergreen boughs. Those which escaped fatal injury from the January frost succumbed to that in March, and the ground is now occupied with another crop.

The total collapse of the autumn sowing is attributable mainly to the sodden condition of the soil at the time of the cold frost spell, and the soft nature of their growth as a consequence. Those who cannot devote glass space to the raising of Peas in boxes need not abandon autumn sowing because of their failure this spring, for with better weather results would be more favourable.—W.

A CACTUS HUNT IN MOUNTAIN AND DESERT.

AT the last bi-monthly meeting of the spring session of the Birmingham Gardeners' Association, Mr. F. A. Walton, Handsworth Wood, Birmingham, made the above the title of an excellent discourse. The lecturer is a large importer of Cacti and other succulent plants, and his extensive collection of Cacti at the "Chrysanthemum Show" last year in Bingley Hall attracted much attention. Mr. Walton has recently returned from America after a three months tour. The subject was illustrated by a series of photographs representing Cacti and other succulents growing in their native habitat.

The description of his travels and adventures in collecting Cacti in California, Texas, and Mexico, was delivered in a lucid, interesting, and humorous manner. He remarked that one of the peculiarities of the Cactus family is that few species, or even varieties, are found in any one neighbourhood, therefore it is necessary to travel over great distances to see any considerable assortment.

Knowing this, and wishing to see and study as many kinds of Californian Cacti as possible, he made arrangements with Dr. C. A. Purpus (who was staying at San Diego, California) to join him upon a botanical expedition across the mountains and down to the Colorado desert. The start was made from San Diego one foggy February morning at 8.30 A.M. in a miniature train, consisting of an engine, one truck, and one carriage, by the Cuymaca line (pronounced Queermacker), passing through some fine fruit growing country, the track winding about considerably so as to avoid heavy gradients, then passing over a ridge some 800 feet high, again going down into the El Cajon valley (pronounced Elkahoon), which is practically a frostless district, where Oranges, Lemons, and Grapes grow to perfection. After a time the sun shone through the fog, and everything looked splendidly bright and clear, with a pleasant breeze that prevented oppressive heat. The hills all round were some 3000 feet high, and the valley, which is about 500 feet above sea level, is splendidly sheltered from all rough winds. The train passed along very slowly, calling at a number of small stations for fruit, or to return packages from San Diego, the market of this district. The hills terminate at "Foster," about twenty miles from San Diego. Foster is the one man there. He keeps the hotel, is station master, runs the stage coach, or rather carriage, which was waiting for the arrival of the train, to take the passengers to their destination.

Directly after leaving "Foster's" the road became very rugged and steep. They had for some time passed beside the San Diego river, which, said the lecturer, should have been called the Sandy river, as there was no water visible, and after crossing they entered a magnificent cañon (all narrow valleys are called cañons in California). The road was sometimes cut into the rocky sides of the mountain, at others it was near the river bed, and sometimes hundreds of feet up the cliff, where a false step of one of the mules, or a bump over an extra large stone, looked as if it would precipitate us into the rocks below. This kind of scenery continued for about seven miles, where they emerged on a splendidly breezy plain or tableland, of about 1600 feet elevation. After passing across about five miles of this, they arrived at Ramond, the place he had agreed to meet Dr. Purpus.

The only Cacti he had seen so far were *Opuntia tuna*, *O. Engelmanni*, in several varieties, *O. prolifera* and *O. serpentina*, none of which were at all remarkable. Next morning at eight o'clock Dr. Purpus arrived, with a strong spring waggon and team of two strong mules. The driver, Mr. Alfred Stockton, a young Californian, had made several botanical excursions with Mr. T. S. Baudesee of San Diego, and Professor Anthony, two of the most noted explorers and botanists in the State of California. The waggon was filled with provisions for themselves and the mules, enough to last a considerable time. After crossing several fine valleys, each at a greater elevation than the last, they at length reached Julian, and where even at the level of 5000 feet they found several varieties of *Opuntias*, although they say that they have frost every month of the year—and the snow was quite thick upon the ground in places.

Leaving Julian they descended rapidly through a most picturesque cañon to the small but thriving mining town of Banner. The road passes down the course of the stream, over boulders, and through pools of water—down, down, always descending, nearly 2000 feet in seven miles. Soon after passing Banner they saw the first of what they considered rare Cacti—viz, *Echinocereus Engelmanni* and *Opuntia basilaris*, but they decided not to get any specimens until the return journey. At length, after another eight miles, they reached their camping ground for the night. The mules had travelled about forty-five miles, having started some eight miles from Romona to their camp, which was about 4000 feet elevation.

Among the various fine specimens of Cacti secured by Mr. Walton was a huge one of *Echinocactus cylindraceus*, and which took several assistants to lift from the ground. Being anxious to investigate the root action of the immense *Cereus giganteus* in its native habitat, he negotiated a specimen about 30 feet high, growing on a high elevation, with all the manual force he could command, and eventually toppled it over, but was surprised to find, considering its size, the comparatively small root anchorage it possessed, though probably about a century old.

In concluding further pertinent remarks appertaining to the Cacti and other flora of the States visited, he humorously remarked that a "Klondyke" is in store for the person who could cultivate such Cacti without spines as food for the oxen, sheep, and goats during a scarcity of other vegetable food.—W. G.

RECENT WEATHER IN LONDON.—Notwithstanding the fact that a considerable amount of rain has fallen of late the wind still continues cold. When the sun is shining brightly it is not so noticeable, but in the evening it is keenly felt. There were one or two heavy showers on Saturday. Sunday and Monday, however, were fine, as was Tuesday. Wednesday opened dull and cold.

WEATHER IN THE NORTH.—The close of April brought no more genial weather. Saturday was one of the most bitterly cold days of the season, and rained throughout. Frost succeeded, and 4° were registered on Sunday morning; the day was bright, but cold. On Monday it snowed heavily for hours in the morning, and the day, till late in the afternoon, was one of November chill and gloom. May certainly brought no promise of milder weather in its opening.—B. D., *S. Perthshire*.

THE ROYAL GARDENERS' ORPHAN FUND.—At a meeting of the Committee, held on the 29th ult., the sum of £32 2s., inclusive of two annual subscriptions for 1 guinea each, was received from the Gardeners' Charity Guild, per Mr. Gerald Dean, Secretary, as the result of the smoking concert held at the Cannon Street Hotel on March 15th. A special vote of thanks was accorded to the Committee of the Guild, and six of its members were placed on the list of life voters.

ANTIRRHINUMS IN POTS.—Those who may not have grown these summer flowers in pots, or seen them thus treated, have no conception of the striking and really effective plants they make for conservatory embellishment in the spring. At the present time I have a number of plants in full bloom, in various shades, that are not only much admired, but are really useful, because they take the place of Cinerarias and Primulas, which have run their course. My plants were obtained from seeds sown in August and wintered in a cold pit, which was well ventilated, so as to keep them sturdy. From here they were shifted into a cool house towards the end of January, and during April they have made a gay and useful floral display. They are not by any means so fleeting as some spring flowers, and they have the advantage of being useful both in the conservatory and the house or as cut flowers for vases. Only the dwarf sorts should be chosen for pot work, as there is a tendency in them to grow tall. The seeds should be sown thinly in boxes, and every encouragement given the plants for sturdy advancement throughout their career. An earlier or later supply, of course, could be obtained by sowing in accordance with the need and time of flowering. I feel sure that those of your readers who have not seen the Snapdragon thus treated would be surprised at the bright show they make in pots.—R. A.

APRIL RAINS.—What a vast amount of good has been done to the country by the abundant rains of the past month. Certainly we have had some cold weather, and especially at nights, but on the whole the month has been more typical of the Aprils of tradition than has been found for several years past. If the trees under the comparatively low temperature open slowly, at least the rains are helping the roots to produce leafage that is intensely green and luxuriant. What do we owe to the early leafing Larch for presenting to us in trees the most precocious of rich colouration amongst deciduous kinds. How the rains have helped to produce that, and also the fine leafage now seen on the earlier Horse Chestnuts. But within a few days and under the influence of warmer weather, all deciduous trees will have put on their spring clothing, fresh and green from Nature's factories, and the country will be indeed lovely to look upon. No trees just now can rival the Pear in beauty. The Plum trees have been very full of bloom, but they are pretty well over, whilst the Pear bloom has but just come in. Nowhere is this more dense than in Mr. R. D. Blackmore's extensive Pear orchards at Teddington, where the free grown trees towering up spirally to considerable heights are masses of snowy whiteness. It may be well with such wealth of bloom everywhere, for thinning, as a means of saving a moderate crop of fine fruits, to be practised. Apple trees are just bursting into bloom, and they will show us a grand body of colour. How richly green and luxuriant is the grass everywhere; a heavy swathe for the mowers now seems inevitable. Gardens look rather bare at present, but crops are coming on rapidly, and in a week or two bareness will have changed to abundant leafage.—A. D.

PELARGONIUM DOROTHY.—The flowers of this fine variety are among the best of those of the regal section, and is not only showy, but a plant of splendid habit, dwarf and vigorous. The trusses are very large, as are the flowers, the colour being a soft satiny rose with feathered blotches of amaranth in the sepals. It is very useful, for it requires no tying, the stems being stout and self-supporting, and this is a consideration where a number of plants is grown. Being so easy to grow it is one of the best for amateur cultivators, who will find no difficulty in growing fine specimens.—R. S. E.

RICHARDIA (CALLA) MACULATA.—Though old and to some extent neglected, this is well worthy of mention as a useful spring-flowering plant, with very handsome leaves. These are halbert shaped, deep glossy green, with transparent white spots, and the spathes are white, with a deep purple centre. It is more strictly herbaceous than the ordinary Arum Lily, and after flowering must be gradually dried off and wintered quite cool, with very little moisture. Repot at the new year, just as the points of growth appear, in a sound rich compost, and water freely when established. It is capital for grouping in the conservatory.—C. W.

OLD AND NEW MELONS.—As the Melon season is coming along the tasting faculties of the R.H.S. Fruit Committee will again be brought into action, that is if the forthcoming season brings so many so-called new varieties to be put on the table as has been the case hitherto. In many establishments we see a few standard sorts, of which Hero of Lockinge is an illustration, still relied on. There are a few old varieties of admitted merit which seem to lose little of their true character in spite of the years they have been grown, and yet in the meantime there have been many new sorts, which have come like a flash in the pan, and gone back into obscurity.—V. T.

TULIPS AT LONG DITTON.—I observe a contributor to a daily paper whose pen seems to have run away with him in floriferous description of the beautiful flowers at Long Ditton. Perhaps because not so enraptured with the Daffodil, I prefer to admire the glorious masses of colours found in the early Tulips at the same place, and I can imagine that any Daffodil enthusiast who has seen the hundreds of thousands of Emperors, Horsefieldis, Barris, ornatus, and others, must hail gladly the diverse and glorious hues of the Proserpines, Globe d'Ors, yellow and white Pottebakkers, De Parmas, and numbers of other early Tulips. How fine are Tulips this year, and what grand blocks of colour they give.—D.

LATE BROCCOLI.—Although while Broccolis are, or have been, turning in this spring rather later than usual, yet because of the comparative scarcity of spring Cabbages, so far seldom have they been more welcome. But very late varieties have great value, as I could but recognise when the other day, looking over a large breadth of Sutton's Late Queen, I saw the weaker plants just turning in, whilst the stronger ones bid fair to furnish larger and very firm white heads all through May. As a rule the variety turns in during the latter portion of May; but in this case, owing to the previous season's drought, the plants started late, and consequently many had not made more than half growth. The strongest ones would be the latest. Some beautiful heads of Model, misnamed something else, were staged by Mr. Wythes at the Westminster Drill Hall on Tuesday. Prices for white Broccolis in shops range from 3d. to 4d. each, and for tiny Cabbages 1½d. There ought to be money in market gardening.—WANDERER.

SPINACH BEET.—An all-the-year round supply of the ordinary or common Spinach is not always a certainty, the weather, both of summer and winter, having a favourable or untoward influence, more or less, on its welfare. Extreme heat in summer causes bolting or premature seeding; excessive rain, such as that which occurred last autumn, sets up a wholesale decay of the root stem, and severe frost destroys the plant. A sowing of Spinach Beet should only be treated as a substitute for the more succulent summer and winter Spinach, and kept as a reserve for times of emergency. The present is a very good time for sowing for affording a supply extending well into the spring of next year, allowing plenty of space between the rows, and when sufficiently advanced for thinning between the plants in the rows too. Freshly manured ground is not desirable; it is better to employ a site that was manured for some previous crop, and this made firm. A vigorous and succulent leaf growth is not that which can best stand the frost, so it is safer to err on the side of poorness, rather than over-richness in the soil. An ounce of seed would be sufficient for a small sized garden, and twice that amount would probably supply the needs of a large one. Any position, except on a sunny south or a cool north border, would meet all requirements in the matter of site.—S.

METEOROLOGICAL OBSERVATIONS AT CHISWICK.

The weather during the past week has been remarkable for cold rains and wind, with bright sunshine at intervals.

— **SUSSEX WEATHER.**—The total rainfall at Stonehurst, Ardingly, for the past month was 3.25 inches, being 1.50 inch above the average. The heaviest fall was 0.70 inch on the 21st. Rain fell on twenty days. The maximum temperature was 67°, on the 28th; the minimum, 30°, on the 12th. Mean maximum, 55.26°; mean minimum, 39.28°. Mean temperature, 47.27°—about the average. The weather up to the 15th was wet, dull, and cold; since then more favourable. Fruit bloom is abundant, strong, and promising, but it has been retarded.—R. I.

— **APRIL WEATHER AT BELVOIR CASTLE, GRANTHAM.**—The wind was in a westerly direction twenty two days. The total rainfall was 2.09 inches, which fell on twenty-three days, and is 0.29 inch above the average for the month. The greatest daily fall was 0.28 inch on the 13th. Barometer (corrected to sea level and reduced to 32°): Highest reading 30.280 inches on the 22nd at 9 P.M., lowest reading 29.001 inches on the 13th at 9 P.M. Thermometers: highest in the shade 63° on the 1st, lowest 24° on the 17th. Mean of daily maxima 51.93°, mean of daily minima 39.06°. Mean temperature of the month 45.49°; lowest on the grass 17° on the 17th and 18th, highest in the sun 113° on the 5th. Mean temperature of the earth at 3 feet in depth, 44.43°. Total sunshine 110 hours 15 minutes. There were three sunless days.—W. H. DIVERS.

— **DAFFODILS FOR AMATEURS.**—Now that the thoughts of everyone are directed towards the Daffodil, let me say a word on its behalf for the beautifying of the small gardens of amateurs and cottagers. These are often bare and cheerless in the spring, because the price of such bulbs as Hyacinths and Tulips is prohibitive to their owners. The same might be said of Daffodils, but we must remember that they are permanent, and, moreover, multiply. Two years ago I was the fortunate recipient of a few bulbs of N. Golden Spur, Horsefieldi, Sir Watkin, Emperor, and others. They were planted in various positions in my garden, and have been admired by all who have seen them. Up to the present they have not been disturbed, but they have increased to such an extent that I am now in a position to supply the wants of covetous neighbours.—A COUNTRY AMATEUR.

— **QUASSIA.**—The trees which furnish so many economical products from the more tropical regions are, in many cases, getting scarce, and those who deal in drugs are continually kept on the watch for other species of trees having similar properties to replace the original ones. There is the Quassia, which is a small tree growing in British Guiana, botanically known as *Quassia amara*, and is getting nearly exterminated; and another tree, known as the Bitter Ash—botanically as *Picraena excelsa*—is largely used for the same purpose that Quassia chips are used. An infusion or tea made of Quassia chips is especially destructive to the green fly and other insects, which are so troublesome to the ladies who grow their own flowers in conservatories. The usual remedies applied by commercial men in the shape of kerosene emulsion, tobacco smoke, tobacco water, and other things, are more or less offensive, while Quassia tea has no objectionable features whatever, and is just as effective. It is a remarkable fact that an infusion of Quassia should be so destructive to the lower orders of animal life, and yet be so harmless to the human system. One may drink it as we drink Chinese tea without any serious consequence.—("Meehan's Monthly.")

— **PRESENTATION AT LEWISHAM.**—On leaving Ryecroft Nursery, Mr. W. Wright, who had been foreman for eight years, was presented with a marble timepiece by the rest of the employes as a token of their esteem for a genial fellow worker. Mr. Mackenzie, in making the presentation, thanked Mr. Wright for his unfailing courtesy to all those placed under him, and, on behalf of all, wished him prosperity in his future career.—H. S.

— **THE EXTENSION OF KEW GARDENS.**—On Monday the grounds of the Queen's Cottage at Kew were for the first time thrown open to the public as an extension of Kew Gardens. There was no opening ceremony, the gates of the fence that separate these grounds from the rest of the Gardens being simply unlocked at twelve o'clock in the presence of Sir W. Thiselton Dyer, the Director. The addition has been made in commemoration of the Diamond Jubilee, but there were only a few hundreds of visitors to the place during the day.

— **THE BUD MOTH CATERPILLAR.**—This pest attacks other orchard trees besides Apples, and the word "Apple" in the heading of my notes of last week was too restrictive. I have found the caterpillars on Pear trees as well as on Apples, also winter moth caterpillars on both. Mr. Hooper of Swanley informs me that he has found a specimen of the bud moth caterpillar on an Apple tree. Mr. Wilfred Youngman of Charsfield, Suffolk, has sent me some specimens of the red moth caterpillar. He says he has noticed them for years past, but had not been able to identify them.—WILLIAM E. BEAR.

— **HOYA BELLA.**—In a strong moist heat this charming little Hoya does well, and as it is very easily propagated and quickly grown we should see more young healthy specimens of it. In many places one comes across old insect-infested plants of it as thick as a Thorn hedge, and a few flowers, but young vigorous plants well established in baskets of rather poor material flower abundantly, and are very striking. Each shoot will have its flower umbel, and the single blossoms are extremely pretty with frosted white petals and an amethyst purple centre. Rough peat, loam, and a few nodules of charcoal suit it well for compost.—H. R.

— **BROWALLIA SPECIOSA MAJOR.**—This is a plant that should have a future before it, by reason of its freedom of flowering, its bright blue colour, and distinctly pleasing aspect as a pot plant. It is easily raised from seeds, but for some strange reason I have failed to find it offered in any seed catalogue until this year. I have not seen it used as a summer bedding plant, but I presume it will, if it does not already, figure in up-to-date bedding. It is distinctly superior in every particular to the older and once popular *B. elatior*, and can be had in flower almost at all seasons of the year. Those requiring variety in pot plants ought not to miss the chance of getting seeds at once and sow.—R. A.

— **GOLDEN PRIMROSE JOHN WILKINSON.**—Last year your correspondent "N. N.," whose communications one reads with interest, sent some flowers of this plant to the Journal office and to the writer. It may be remembered that I ventured to speak favourably of the flower, which is, as I remarked, really a Polyanthus. Through the kindness of "N. N." I have had the opportunity of testing the plant by growing it, and it is only due to him to say that it is more than satisfactory, and that it fully surpasses the expectations formed of it last year. It is very free flowering, and the effect produced by its golden-yellow flowers is exceedingly fine.—S. ARNOTT.

— **CANARY GUANO.**—A sample of this fertiliser, as advertised by the Chemical Union, Ltd., Ipswich, has been sent to us for an opinion thereon. We can substantiate the claim for it that "it is perfectly clean and may be used by a lady," and to this can add if it be applied in solution to the soil in which plants are growing in a boudoir, its use would not be detected—except by the plants. The fertiliser is in the form of fine dry grey powder, and readily dissolves in water. The familiar odour of guano is present, though evidently "masked," as the doctors say, by something else. We once had some manure sent to us for trial, and after observing that small or large doses had the same effect, or no effect, on Auriculas, we potted a couple of plants in it. They grew very well throughout the season, and thus ended the use of that particular manure. If it possessed the merit of containing nothing in it to injure plants on the one hand, it contained nothing to benefit them on the other. It is not the same with canary guano, for after a few short experiments with it on Hyacinths in pots, it was evidently enjoyed by some to which it was properly applied, while others, which were purposely overdosed, had a struggle for life. There is thus "something in it," and the clean powder must be used according to instructions for obtaining the best results that it is capable of producing.

FIELDS OF WAVING GOLD.

A WRITER in the "Daily News" no doubt feels fortunate in the discovery that Messrs. Barr & Sons' nurseries at Long Ditton form "the yellowest spot on earth," and we may, therefore, be pardoned for choosing the above title for our notes of the Daffodils there flowering. That it will to some persons sound overdrawn we do not doubt, but by those who have paid a personal visit, or have even passed in the train, it will be accepted as perfectly true. Standing at either of the several entrances the fields have the appearance of waves of brilliant yellow rippling with the gentlest breath of wind. It is a spectacle to which many an on-looker might aptly apply the historical appellation of "The field of the cloth of gold," and there would be little or no exaggeration. No one can faithfully picture in the mind the exquisite beauty of the countless thousands of

FIG. 82.
NARCISSUS INTERMEDIUS SUNSET.

flowers rising amidst the green ribbon-like leafage; nor could anyone forget the scene after an inspection had been made, no matter whether they were Daffodil enthusiasts or not.

As the years roll on the number of varieties—or it may be supposed some persons would prefer to say hybrids—becomes greater, and only specialists can keep pace with the times. As a matter of fact, it is the trained mind alone that can appreciate the difference in some of them. There are, however, enough and to spare of varieties at prices ranging from a penny up to 15 guineas a bulb that are quite distinct, and of a beauty that appeals forcibly to all tastes. With a scope like this, it cannot be wondered that "Daffs" are seen in almost every garden in town and country. We might, in notes of this nature, confine our remarks to the newer and rarer varieties that are beyond the reach of all but the most highly favoured, and in doing so, be forced to omit mention of older, commoner, but not really less beautiful sorts. Such of those we shall refer to may not have the noble beauty of Monarch, the stately mien of Weardale Perfection, the exquisite delicacy of the shading in Apricot, the refined softness of Lady Helen Vincent, the boldness of Shakespeare, the chasteness of L'Innocence, or the purity of Mrs. Morland Crosfield; but they have other merits that endear them to lovers of spring's golden flower.

We shall in as few words as possible advert to varieties that have some striking characteristic which alone renders them worthy of culture, either in the borders of the small town gardens, or the beds and borders of the country home. That they flower magnificently in small, smoky London gardens we have had many proofs, and that some varieties at any rate increase and multiply under these conditions we know from

personal experience. Then there are in many gardens grassy dells and broad expanses of turf in which Daffodils can be planted, indeed under no other conditions do they look so well. To all whose facilities permit of it, we say plant sound bulbs in grass, for such is their rightful home. In the early days of the year the blades of the leaves will cut through the turf, and as spring advances so does the bud, until the stout footstalk is crowned with a nodding smiling flower. Too many cannot be utilised for such a purpose, as no one could tire of their delicate beauty. True, care has to be taken in the initial selection, as some thrive far better than others, but with the surmounting of this difficulty the grower's troubles are over, and he has only to wait for a sure reward.

It is more than probable that those of our readers who reside in or near the metropolis would visit the Drill Hall in James's Street, Westminster, on April 18th, when the Royal Horticultural Society held one of its popular meetings, and those who did so might have then noticed *N. intermedius* Sunset, which is represented in fig. 82. It is not new, but sufficiently beautiful to receive an award of merit from the Narcissus Committee. As may be seen it is of the small tazetta type, the colour being canary yellow in the perianth and rich orange in the cup. It has the additional recommendation of being delightfully fragrant, resembling the Jonquils in this respect. Of these latter we need say nothing, for they have been popular favourites for more years than one cares to remember. Possessed of the same desirable attribute—perfume—is the chaste *juncifolius*, or Rush-leaved Daffodil, with whose chaste beauty everyone is familiar. Look, too, at *cyelamineus*, *triandrus*, *corbularia*, *Backhousei*, *Macleai*, and *Nelsoni* in variety, and think of the diversified beauty that can be found in these half dozen types! Not one variety of the whole can reasonably be omitted from a collection that has any pretensions towards completeness. There is a tender charm about them all, but in none more than the prettily named "Angel's Tears."

Let us, however, turn now to a section that is probably as large as the above six combined—namely, that which is distinguished by the appellation Leedsii. Of this type we have chosen a group of four for reproduction (fig. 83), to which we have added a variety of *incomparabilis*, known as *Stella superba*. The latter is one of the most attractive specimens in the Barr museum, and has a habit of looking one straight in the face. It is an enlarged and improved *Stella*, which is an ample description for anyone. Reverting to the Leedsis there represented, we see at the top on the left *M. Magdaline de Graaff* with its broad white perianth and rich, deep yellow cup; in the centre *Princess of Wales*, which has a white divided perianth, and a fimbriated cream cup; and on the right is *Gem*, an established favourite, and one of the best of the section; with, at the bottom on the left, *Duchess of Westminster*, which is white, with a long delicate cream crown; *Stella superba* occupying the lower right hand corner. There are other Leedsis besides these, but they will suffice as examples of a charming type of the Daffodil family that produces flowers in abundance of the greatest value for cutting.

Turning to those that are distinguished as Barri, after the renowned firm whose flowers we are reviewing, we are constrained to commence with conspicuous, than which no Daffodil of any section is more beautiful or more generally admired. A score of thousand bulbs produced such an effect as to impress everyone and to send the enthusiast into ecstasies of rapture. One of those in the party when these notes were made went down on his knees, the better to appreciate the glow of crimson on the carpet of gold. And they were worth it. *Flora Wilson*, with its white perianth, is very showy, as is *Sensation*, of which the soft yellow crown is margined with red. Smaller than either the Leedsii or the Barri sections are the varieties of *Burbidgei*, which come with poetical and a few others in the category of "true" *Nareissi*. Of these we were particularly attracted to *John Bain*, *Agnes Barr*, *Falstaff*, and *Mercy Foster*, though the others would be considered by many as of equal beauty. There can be no necessity to dilate upon the beauty and value of the poetical section, so well is it known, but it may be said in passing that the merits of poetical *præcox grandiflorus* for early flowers entitle it to more recognition, as it is several days ahead of *orratus*.

From the very small we will transfer our attention to the very large, to the section that claims *Monarch*, *Weardale Perfection*, *Apricot*, and *Mrs. Morland Crosfield* as its own. Here we have boldness in the flower, richness and diversity of colouration, with strength of constitution—merits that place the *Magni-coronati* group at the top of the tree. Leaving the very expensive, where, may we ask, will a better Daffodil be found than *Emperor*? We will answer ourselves in one word, and that is, *Nowhere*. It is simply superb. Equalling it in beauty, if not in size, is *P. R. Barr*, which is rather more refined. But what of *Golden Spur*, *Ard Righ*, *Henry Irving*, *maximus*, and *M. J. Berkel y*? Nothing; their names are quite sufficient. There must be included some bicolors with their white perianth and yellow cup; they are too beautiful to be omitted. We should choose *Empress*, *Horsefieldi*, *Madame Plomp* (if not too high in price), *Victoria*, *Mrs. Walter Ware*, and *grandis*, the latter particularly for late flowering. Each of these is worthy of a place in every garden. Then, too, we have the sulphur coloured varieties, which appeal strongly to most growers. These are numerous, and the shades of colour in both perianth and trumpet are so delicate that personal selection is almost absolutely essential.

It would be an unjustifiable action for any writer treating of Daffodils to omit reference to the *incomparabilis* section, *Stella superba* being so far the only one to which reference has been made. Who does not grow the splendid *Sir Watkin*? It is, perhaps, one of the most popular varieties in cultivation, and rightly so. If it were more abundant, what a favourite *Gloria Mundi* would be? Unfortunately the price of 25s. per bulb is

somewhat prohibitive. It is one of the loveliest flowers we have. If not quite so showy, there are many that are equal for general purposes, of which Gwydyr, Beauty, C. J. Backhouse, Autocrat, and Frank Miles may be cited as examples. For cutting purposes and for naturalisation in grass the varieties of incomparabilis are probably unrivalled, and will become more and more grown for these purposes alone. Then, too, there are the double forms, which appeal to many persons, though not to all. Of these Butter and Eggs, Eggs and Bacon, and Codlins and Cream are the best known.

The season of the Daffodil is passing for another year, and though there will be flowers for many a day, their greatest beauty will be seen no

at the present time is appalling. Gardeners have at all times been prepared to lose some of their Gooseberry and Currant buds during the winter, and Green Peas, Lettuce, and other vegetable plants in summer, as well as a portion of the ripe fruit; but I think it is quite a new departure for tomtits, sparrows, bullfinches, green linnets, and other birds to take to the Apple, Plums, Pears, Cherries, now nearly or quite in bloom. They simply nip out every flower bud, eat the short pedicel, and let the other portion fall to the ground. One other fruit bush I forgot to mention is the Black Currant. This they will completely ruin if not checked promptly. I have never known any birds to interfere with Black Currants before the present season.

FIG. 83.—GROUP OF NARCISSI.

more until another century has been ushered in. But there yet remains sufficient at Ditton to appease the keenest appetite, and those who would visit the display should do so at once. During the next week or two there will be Daffodils in numbers and Tulips in abundance, not to speak of other flowers that lend their aid towards the glories of spring. —ENTHUSIAST.

BIRDS AGAIN.

I THINK that the time has come for some decisive action to be taken in order to keep those birds which are destructive to garden and field crops within reasonable limit in numbers. The amount of damage being done

Quassia chips were formerly quite sufficient to keep them off, but neither this nor cotton is of any use now. The damage does not end in the kitchen garden—they are equally destructive in the shrubberies. Amelanchiers, Viburnums, Japanese Cherries, Weigelas, Pyrus, Thorns, and other flowering shrubs are ruined for the present season—not only so far as their flowers are concerned, but in many cases the stems will be quite bare, and will require cutting back much in the same way as Gooseberries and Currants sometimes require to be pruned.

This is a kind of thing which will not get better, but will become worse as birds increase (which they undoubtedly will), now that they have acquired a taste for the buds at this season of the year. We must not destroy them during the spring and summer months but we need not forget them after the close season.—T. ARNOLD.

STOCKS FOR FRUIT TREES.

"HAVING read with pleasure Mr. Lambert's and Mr. Pearson's observations on stocks for fruit trees, on pages 314 and 337 respectively, I should be glad if you could find and republish an article by the late Mr. Thomas Rivers, which appeared in the *Journal of Horticulture* about thirty years ago. I have often thought it was the best contribution on the subject I have ever read, and many times regretted I did not preserve it. I can only say, as a guide for its discovery, that it appeared soon after the title of our Journal was changed from the 'Cottage Gardener.' As a young gardener then, the article interested me greatly, and I took some extracts from it, and I am sure it would interest many readers who have not seen it, as well, perhaps, as some who have a reminder of old times and old masters." Thus writes an "Old Gardener," and we are glad to comply with his wishes. We may now say that Mr. Lambert's article was written for and read at a meeting of the Herts Gardeners' Society, a fact that was not stated on his M.S. The following is Mr. Rivers' article.

STOCKS FOR APPLE TREES.

There is, I think, nothing more interesting to the practical horticulturist, and I may also add, to the theorist, than the influence of the stock on the graft, in plainer words, on the tree grafted on to a stock, and the converse of the proposition, the effect of the graft on the stock. The latter being of a far more extensive nature than the former, yet, as it seems to me, not much known or expatiated on by horticultural writers.

INFLUENCE OF STOCKS.

There is, as far as I have experienced, no fact so prominent in fruit culture as the effect of the Paradise or surface-rooting stocks on the Apple tree. By the simple choice of a stock we can make a giant into a pigmy; and such varieties as Bess Pool, of which I have seen trees rivalling large Oaks in magnitude; the Bedfordshire Foundling, the Tower of Glamis, the Blenheim Orange, and other vigorous-growing sorts, can be at once reduced to small garden trees, rapidly arriving at a sort of premature maturity, and bearing profusely, which is brought about by merely selecting the kind of stock likely to produce such a result.

THE FRENCH PARADISE.

The variety best known by the gardeners of the last century is that which we now call the French Paradise, "Pommier de Paradis." This would seem to be of Eastern origin, for some few years since the London Horticultural Society introduced the "Dwarf Apple of Armenia," which, as far as I could judge, was identical with the Pommier de Paradis. This kind of stock is noticed by Miller in his Dictionary, in the edition about 1750. I append an extract from it, which may interest some of your readers, showing as it does that there is nothing new in what has been said in your columns about Paradise stocks.

The peculiarity of the French Paradise is its remarkable effect on the graft, dwarfing it to an extent scarcely credible. The proportions of growth are something as follows:—A tree two years old on it will be about 2 feet in height, and covered with blossom-buds. A tree of the same age, and growing under the same circumstances, grafted on the Doucin, will be from 3 to 4 feet in height, and well furnished with blossom-buds, but not so abundantly as the tree on the French Paradise. A tree on the English Paradise stock will attain the same height, and be in the same condition as to bearing as that on the Doucin. A tree grafted on the Crab or Apple stock will at the same age be 7 feet high, and unless one of our free-bearing sorts, such as the Keswick Codlin, Hawthornden, and some kinds of the like habit, will be bare of blossom-buds. I give these results not as being exact, but to convey an idea of the effect of the different stocks I have named.

EXPERIMENTS.

The Pommier de Paradis has been found too delicate for some soils and sites in England. I have found it so at Sawbridgeworth, and Mr. Pearson of Chilwell has experienced the like in his deep fertile loamy soil. Fearing that I might have made my two or three essays on a soil too cold, I made a further trial, and had 500 planted in a fine deep sandy loam, in the middle of a quarter, with 500 Doucins on one side, and 500 English Paradise on the other. The Pommiers de Paradis nearly all soon died from canker—no frost seemed to do them any injury—while the two kinds of stocks I have named here produced healthy trees free from any disease. It seems, therefore, that in some soils and sites this stock is delicate. Against this we have the experience of Mr. Scott, who states that with him this stock is perfectly healthy. This is, no doubt, owing to his warm, fertile soil, and the soft air of Somersetshire, which is very different to the harsh, dry air of Hertfordshire.

There is a curious fact relative to this stock which belongs to my second postulate, but should be mentioned here. If a healthy graft is

placed on a French Paradise stock the first year after being planted (stocks are for the most part grafted the second year), it seems to give health and vigour to the stock and to rescue it from canker. It is very curious to see trees in pots on this stock after three or four years' growth; the graft swells over and forms a large circular protuberance, as if impatient to escape from its thralldom; and the roots of the graft break out close under the swollen part; so that if the base of the graft were covered it would put forth roots, and, to use Miller's words, "would be equal to no stock." It is exceedingly interesting to watch in the graft this apparent yearning for more food. Apple trees on the Pommier de Paradis form the prettiest and most fruitful of all bush trees when cultivated in pots. Seedling pigmy stocks have been raised here. These will probably prove hardier than the French Paradise, and have the same dwarfing tendency.

THE ENGLISH PARADISE.

The second kind of Paradise stock deserving of a few words is the English Paradise stock—a very old variety, which some thirty or forty years ago I used to receive from the Knap Hill Nursery, where it was propagated by layers. It was very distinct in its habit, and had rather large roundish leaves and pale bark. As far as I recollect, this was the only kind of Paradise stock employed in those days, and then to a very limited extent; for 100 Apple trees on Paradise stocks then sold I should calculate that 5000 are now (1867) sent out by nurserymen. There are some seedling stocks of this race—two raised here, and one of them, called the Broad-leaved Paradise, resembles the sort I shall next describe. They all swell with the graft, and produce healthy, fruitful garden trees.

THE DOUCIN.

The third variety of the Paradise stock race is the Doucin. This is probably of French or Dutch origin. There are several varieties of it, some of them worthless from their liability to canker. Those with small leaves like the Crab are to be avoided. The true sort has large pointed leaves of a dark green; the bark on its young shoots is of a very dark brown spotted with white; its leaves are more pointed than those of the Broad-leaved Paradise mentioned above, and not quite so large; it does not swell with the graft so well as the English Paradise stocks, but it forms healthy and fruitful garden trees.

THE BURR KNOT.

The next race of surface-rooting Apple stocks is the Burr Knot, the old variety. The Burr Knot of most of our gardens bears very fine fruit, and is a valuable kitchen Apple. Like all of the Paradise race of stocks it roots from truncheons, or stout two and three-year-old shoots, planted in the ground, reminding one of the orchardists at Valparaiso and other parts of Chili, who do not plant a tree but a branch, which takes root, and at once forms a bearing tree. This brings to mind the Burr Knot Apple at Ware Park, Herts, there called "Byde's Walking-stick Apple," simply because an old magistrate who lived there early in the present century used to stick in a branch of the Burr Knot wherever he thought an Apple tree wanting. The trees are there still (1867).

The "burrs" which form on the stems of Apple trees are, or seem to be, bunches of incipient roots. The English Codlin, formerly employed as a dwarfing stock, and mentioned by Miller as being used for that purpose, has burrs on its stem; and stout shoots, planted rather deeply, will root and make dwarf prolific trees.—T. R.

[Extract from Miller's "Gardener's Dictionary," 7th edition.]

"The Paradise Apple hath, of late years, greatly obtained for stocks to graft or bud upon, but these are not of long duration; nor will the trees grafted upon them ever grow to any size, unless they are planted so low that the cyon may strike root into the ground, when it will be equal to no stock, for the graft will draw its nourishment from the ground, so that it is only by way of curiosity or for very small gardens that these stocks are proper, since there can never be expected any considerable quantity of fruit from such trees.

"These trees have been much more esteemed in France, where they were frequently brought to the table in pots growing with their fruit upon them; but this being only a curiosity it never obtained much in England, so that the gardeners do not propagate many of them here at present.

"There is another Apple, which is called the Dutch Paradise Apple, much cultivated in the nurseries for grafting Apples upon, in order to have them dwarfs; and these will not decay or canker as the other, no do they stint the grafts near so much, so are generally preferred for planting espaliers or dwarfs, being easily kept within the compass usually allotted to these trees."

[Young gardeners and others will recognise that the Paradise stock is not so modern as some of them conceive it to be, as these observations by Miller were written 150 years ago.]

ROSE SHOW FIXTURES IN 1899.

- JUNE 13th (Tuesday).—Cambridge.
 „ 14th (Wednesday).—York†.
 „ 21st (Wednesday).—Isle of Wight (Shanklin).
 „ 24th (Saturday).—Windsor.
 „ 27th (Tuesday).—Westminster (R.H.S.).
 „ 28th (Wednesday).—Bath, Croydon, Maidstone, Reading, Richmond, and Ryde.
 „ 29th (Thursday).—Canterbury, Eltham, Norwich, and Sutton.
 JULY 1st (Saturday).—Crystal Palace (N.R.S.).
 „ 4th (Tuesday).—Gloucester and Harrow.
 „ 5th (Wednesday).—Brockham, Ealing, Hanley*, and Tunbridge Wells.
 „ 6th (Thursday).—Co'chester (N.R.S.) and Farningham.
 „ 7th (Friday).—Hereford.
 „ 11th (Tuesday).—Wolverhampton.†

* Show lasting two days. † Shows lasting three days.

The above are all the dates definitely decided upon that have as yet reached me. I shall be glad to receive the fixtures of any Rose shows not named above, or those of any horticultural exhibitions where Roses are made a leading feature, for insertion in future lists.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

ROSES AND ROSE CULTURE.

A FEW weeks ago we made reference to the latest edition of "Roses in Pots," by the recognised master in the art of culture and description, Mr. William Paul, F.L.S., V.M.H., of Waltham Cross. The author now sends us what may be termed his Yellow Book, under the title above given. It is the ninth edition of the work, in which he deals clearly, concisely, and practically with Rose growing generally. The various forms in which the plants are cultivated and trained are described and shown, and selections of varieties in the different sections given for the guidance of the inexperienced. It is an excellent shilling's worth, and many amateurs and gardeners who do not already possess it, might with advantage have it handy for reference. It is compact, pleasantly written, usefully illustrated, and trustworthy.

RECOLLECTIONS AND REFLECTIONS.

RECOLLECTIONS are pleasant memories sometimes, but not always; yet methinks always with regard to bygone days in the journey of horticulture. Reflections, closely allied to recollections, lead us to weigh, very thoughtfully, whether we are always on the right track in the journey of our gardening life. So let it be for a few moments with our old associations in that branch of horticulture anent Queen Flora.

No one for a single moment would, I presume, venture to declare that we have not progressed; in fact every genuine horticulturist belongs to the progressive party (politics excepted). We cannot help ourselves—Nature, urged on by Divine assistance—i.e., the power given to man by the Great Power, has by this power of intelligence, study and perseverance, brought about what some folk are foolish enough to call a "revolution" in horticulture, but which I would rather call a progressive evolution.

This progression or evolution is more and more in evidence every day, and that in every branch of horticulture. The fittest has survived, and yet only to be improved upon, for every day we are perforce impelled to recognise this improvement. For instance, take Peas, *Pisum sativum*, think of the marvellous progression in this class; but you have to go back to the fact that the best varieties now in vogue have in them the old "blood" of the best Pea of years ago; it is not a new Pea exactly, it is an improvement, a progression. We have only to re-read Mr. Sherwood's paper in the Royal Horticultural Society's Journal to verify my statement. The same may be said of the Potato, and the evidence thereon given by Mr. A. Sutton, the veteran Mr. Fenn, and others. All this bears out my argument. So much for these so-called vulgar, but very useful, aye! necessary and delicious vegetables.

But, you ask, how does this affect, or what has this to do with Roses? I must apologise for preambling, but I will, with your

permission, bring once more to my own recollections, and reflect thereupon, some happy experiences *re* old Roses—partly for their own sakes, partly for the share they hold in the present state of their magnificent issue.

The late Mr. Shirley Hibberd wrote, "Let oblivion's curtain fall upon the origin of Roses." Was he right? Perhaps so, and yet perhaps not so. Without a doubt we can distinguish characteristics in our hybrids, which clearly show pedigree blood—show it in wood, leaf, and habit; and these distinctive "marks" seem to be the more intensified in the progression towards perfection. Take *La France*. Can you not see in the wood alone the old pink China? Then let us thank God for giving us the old pink China. I suppose that there is no more generally popular Rose than *La France*. Take any popular or aristocratic "occasion" where flowers in the Rose season are to be in evidence, and you will find that Covent Garden is at its wit's end to get blooms enough of this Rose to supply the demands of its importunate customers.

Again, has not dear old Général Jacqueminot a debt due to him? And, once more, that lovely coloured, mildewed-ever, yet splendid parent, *Géant de Batailles*? Reflect, ye young men of 1899? Fifty years ago, in 1849, 8000 plants of this variety were distributed in this country by Mr. Thos. Rivers.

Have you bent in rapt enthusiasm over a lovely bloom of *Senateur Vaisse*, a *Charles Lefebvre*, a *Maurice Bernardin*, or a *Duc de Wellington*? Then think of the progenitor, *Géant de Batailles*. Alas! alas! that we, poor human creatures, should so oft forget how much we, in our prosperity, owe to our human progenitors, and how little we value that worth and energetic love in them which has placed us in the position which we now hold. Success is too often blind to perceive its source.

So much for "reflections." To go back for a moment to recollections. There appears to my mental eye a real old-fashioned garden, with its broad central walk, on either side a 3 or 4 foot border filled in with herbaceous stuff (but surely this usual gardening term "stuff" is a very uncomplimentary one), and at intervals I see some grand standards "massed in bloom," of such free flowering Roses as *Duchess de Cambacères*, *Blairii* No. 2, *Jules Margottin*, *Acidalie*, *Anna Alexieff*, and others of like growth.

Yes! The exhibitor's craze is doing good, very much good, especially in the decorative department, but for all this my own eye will not allow itself to be dimmed to the sight of the great grandfather Roses which have enabled the Dicksons, the Pauls, and the others of these late years to "bring forth fruits unto perfection."—J. A. W.

PETUNIAS.

THIS beautiful showy half-hardy perennial has been greatly improved in colour, size of flower, and habit of growth. There are both tall and dwarf, single and double varieties flowering. The dwarf are excellent for bedding, as they grow only about 6 inches high. The tall also answer for bedding, but they must be pegged down. The singles are the showiest, and generally the most floriferous for outdoor culture, and are readily raised from seed, which ought to be sown in March, the seedlings being grown in 6-inch pots until time for bedding out. Heat is only required until the plants are established in the pots, affording them afterwards a cool, airy position to render them sturdy for planting. Rich soil is not required for Petunias when planted, as this will cause them to grow more vigorously than is desirable for freedom in flowering. Poor soil will give the best results, and a dry time, too, is more favourable for a good display of flowers than moist weather.

Petunias are very effective as pot plants, when grown in compact form by frequent stopping of the shoots and tying them out. The double varieties are more easily dealt with, as they are naturally sturdy growers, especially when grown from cuttings, which, however, should only be preserved from approved and select varieties. Plants for blooming early in the year may be obtained from seeds sown in August, wintering the plants in 3-inch pots, and shifting them quickly in early spring in plenty of light and heat. The best compost is loam, leaf soil, and sand, potting the plants firmly and pinching back as necessary. Watering is important, as they must never want for a supply. The plants flag seriously on becoming very dry, and the leaves are liable to turn yellow at the base.

Plants not raised in autumn may be obtained from seeds sown in January, February, or even March. Pans or boxes are preferable to pots, as a good wide surface is available, on which the seeds may be distributed evenly and thinly. There is no waste of seed, and the plants germinate and grow stronger. Equal parts of loam and leaf soil, with sand, may form the compost, pressing it down over the drainage, and filling up to an even surface. Water with warm water, and after draining scatter on the seed, covering with fine white sand. Place in a temperature of 60°, and sprinkle very lightly to maintain the requisite moisture for insuring germination.

A warm moist base of cocoa-nut fibre refuse is very suitable. Give special care when the seed is germinating so that the soil is neither dry nor wet. When the seedlings can be readily lifted transplant an inch apart. The next move must be to 60-pots, following with 5-inch or 6-inch size. Afford shade and sprinklings of water to encourage growth, but the plants must also be moist at the roots.

After potting keep closer for a time—a week or ten days will be long enough—then afford more air. Stopping the most vigorous growths must be practised, so that the plants may be even and regular.—E. D. S.

GOOD WORK AND GOOD HINTS.

It is pleasant to find good work of whatever kind and wherever seen in gardening, and to take and record hints that may be useful or suggestive. It is feared that many a good point is seen, and momentarily admired, but for some reason or other—or no reason—is passed by as if it were unworthy of public mention. I will not make the mistake of thinking that what I have had the pleasure of seeing lately in a florist's establishment at Derby will be of no interest to others, for I believe many may like to know of what afforded satisfaction to one who has had opportunities for seeing good work of the kind in which readers of "our Journal" are interested.

THOUSANDS OF ARUM LILIES.

Those which I have to refer to were to be seen "in their thousands" in pots, boxes, and planted out. All were in full flower, and had been since last November. Those in pots were really magnificent specimens. They were in 10-inch pots, each containing three large selected crowns, and my attention was called to the striking fact of every leaf having its flower bud springing up soon after full leaf expansion. This free flowering was attributed to the thorough resting and drying off which the plants have in summer. They then become quite denuded of leaves, the crowns are well ripened, after which they are assorted, the finest being potted, the next size planted in boxes or on shelves, all of them coming into flower in November, and proving a source of profit for six or seven months.

A BRILLIANT WALL OF "RASPAILS."

Imagine a wide and lofty span-roof house, ends east to west, with an interior wall along the entire length of it, shutting off about a third of the width for a north house for Ferns. About a year ago the valuable double scarlet Zonal Pelargonium F. V. Raspail was planted out of 48-sized pots in a narrow border along the entire length of 100 feet on the south side of this wall. They now cover the wall to a height of about 6 feet, and are laden with thousands of the compact rich scarlet trusses, although flowers had been cut all the winter. If my memory serves me aright Mr. Cannell once showed me a "Raspail Improved," but I very much question if it can be an improvement upon the free-flowering of the original as I saw it. I used to admire it very much at the Horticultural College at Swanley, where large quantities of it were grown in pots for cut flowers for market, but I never realised its true value and beauty till I saw it on the wall referred to. It looks like growing to the top of the wall, I know no reason why it should not, and if it does it will not only be a lovely but an instructive sight, as showing how profitable an interior wall may become under skilful management. On a side stage a large quantity of *Lilium longiflorum* was remarkable for vigour of growth and promise of flower, there being from three to six buds in each pot with four to six flower buds upon each of them. My attention was called specially to these plants as being from Japanese bulbs, and altogether superior to the growth from Dutch bulbs last year. A thousand Tuberoses were being started in shallow boxes under the side stage.

WHITE MARGUERITES AND THEIR LEAF-MINING ENEMY.

"White Marguerites are always in demand, and always go well," I was told, as I came upon thousands of plants full of bloom. The system of culture is spring propagation, bedding out in summer, lifting and potting in August; they then flower in September, and continue flowering till spring. Some trouble had been experienced from attacks of leaf-miner insects. These insects are often troublesome amongst *Chrysanthemums* and *Cinerarias*, as well as *Marguerites*. I saw a fine lot of *Cinerarias* last season so disfigured by leaf-miners as to be practically useless. It may be well to mention here that the remedy for this pest is tar water, made by boiling half a gallon of coal tar in a gallon of water, to which, when cool, add 50 gallons of clear water. Spray thoroughly over plants, stage, woodwork, and glass. In the use of this, as of all other insecticides, prevention should be our aim: when the presence of the pest is suspected, occasional spraying prevents attacks—a far better plan than trying to cure a bad case of infestation, for the foliage has then suffered beyond recovery.

ACKNOWLEDGMENTS.

It would only be fair to say that such objects as I have briefly described and the hints recorded are the outcome of a visit to Mr. F. Lewis, a most capable florist and decorator at the Mile Ash Nursery,

Derby. It would serve no useful purpose to enumerate a list of the many flowers grown there. I have said enough to show something of good work done by a good man—work so well done that it has its lessons for others, among which not the least is the industry, energy, and intelligence that are brought to bear upon it, and the success which is already crowning efforts so well directed, and energy so well applied.—EDWARD LUCKHURST.

PERENNIAL BORDER FLOWERS.

ALYSSUMS.

WHILE several of the Madworts are more suitable for the rockery than the border, there are still some which may be used in the latter with advantage. Of these, *A. gemmonense* may be mentioned as a desirable species, although not quite so hardy as *A. saxatile*. It has the merit of flowering over a longer period than that species. It grows about a foot high and produces a profusion of small yellow flowers. There is a variety with paler flowers named *A. gemmonense sulphureum*.

Alyssum saxatile is the most valuable of the genus for the border, where masses and clumps make a brilliant effect in late spring and early summer. It flowers profusely, and is very showy with its small bright yellow flowers, which quite cover the foliage. The latter is of a hoary grey. Of *A. saxatile*, which has the popular name of Rock Madwort, there are four varieties. One is *A. s. compactum*, of dwarfer habit; another is *A. s. variegatum*, which is pretty but rather tender; the third is *A. s. Tom Thumb*, a very dwarf form which is not so free-flowering as the type; and the fourth, *A. s. fl.-pl.*, a double form. Another border species is *A. Wiersbeckii*—a summer bloomer—which grows about 1½ foot high and has yellow flowers. The Alyssums are easily raised from seeds or by means of cuttings taken off with a heel in spring or early autumn, and inserted in sandy soil under a hand-light or frame. *A. saxatile compactum* does not come quite true from seed, and *A. s. variegatum* ought also to be propagated by cuttings. The Alyssums are very useful in the border, and *A. saxatile* has often been used for spring bedding. It flowers more freely, however, when left undisturbed.

AMSONIAS.

The Amsonias—named in honour of Charles Amson, a traveller—are so seldom offered that it seems needless to say much about them; yet the grower of hardy flowers may like to know at least a little about them. They are hardy plants, which come from North America. The only members of the genus included in the "Kew Hand-list" are *A. tabernamontana* and its variety *salicifolia*. The former has pale blue flowers with narrow lobed corolla, and a tube of a funnel shape and ovate lanceolate leaves; the latter has light blue flowers with a white throat, and is of less upright growth than the type. They are grown in borders with a little shade. They may be divided in spring. The Amsonias are not particularly showy.

ANCHUSAS.

A few of the Anchusas or Alkanets are quite hardy and perennial, but what the writer considers one of the best—*A. italica*—is only a biennial in most gardens. It has brilliant blue or purple flowers and grows about 4 feet high. *A. sempervirens*, although naturalised in some parts of Britain, is worth growing in rough borders, where its fine blue flowers look well. For "wild gardening" it is well adapted. It grows in one spot by the wayside a few miles from where the writer lives, and, growing among other herbage, gives a pretty effect; it is also pleasing by the sea in half-shady places. It grows about 2 feet high. *A. Barrelieri*, which grows from 1½ to 2 feet high, and has white tubed and yellow throated blue flowers, is a native of the southern part of the continent of Europe. It is not, however, hardy with the writer. *A. italica* and some of the others of the genus are favourite bee plants; this may recommend them to some. The Anchusas are increased by seeds.—S. ARNOTT.

(To be continued.)

"TRIMMINGS."—When the ladies at the hall send down to the garden, as they do once or twice a week for flowers, the order generally has tacked on it, "and plenty of Fern or foliage." Ah! we say, that's all right as to flowers just now; we have pretty well of Roses—*Maréchal Niel*, *Gloire de Dijon*, *Niphetos*, *Souvenir d'un Ami*, and *Catharine Mermet*, indoors and out; *Daffodils* in many varieties, *Hersefieldi* a special favourite; but as to "trimmings," as this green decorative material is called in the bothy, that is another matter, with the *Adiantums* and Ferns generally all cut down and repotted to go on to do their work in the coming season; but something must be found, and, turning round, "Oh, here it is!" That friend in need proved to be a large plant of the Climbing Fern, *Lygodium scandens*, and right well it serves, with its fine fronds of two sorts, the plain ones unfertile and the crinkled ones fertile, thus providing variety at once, and without going anywhere else. Another Fern, which is most useful at this empty time is *Nephrodium molle*, which sows itself all over the stove, and is generally to be depended upon for a few good fronds. As a variation from the greenery commonly sent in with flowers we find that variegated foliage is often very acceptable as "trimmings," and we therefore occasionally send in variegated *Panicum*, *Tradescantia zebrina tricolor*, *Strobilanthes Dyerianus*, leaves of the many varieties of *Begonia Rex*, and stray shoots of *Coleus*. It is wonderful how ingenious we can be when necessity drives, and variation or change breaks up the monotony of life, and adds a charm even to prosaic surroundings.—P.

BORONIAS.

FEW hardwooded plants produce flowers having so delightful a perfume as some of the Boronias, and on that account alone they are certainly worthy of being grown in gardens generally. The well-known variety *megastigma* is especially noteworthy on account of its odour, for a few sprays of it placed in a glass will fill a room with its pleasing scent. The flowers, though peculiar in appearance, can scarcely be termed showy; but being borne on slender shoots, are elegant and interesting, as they supply a pleasing contrast to more gorgeous greenhouse plants. *B. elatior* produces rosy carmine flowers very profusely, and is a decidedly bright and pretty variety, which all Boronia growers should obtain. Other good varieties are *B. anemonæfolia* (pink), *B. crenulata* (red), *B. Drummondii* (rosy pink), *B. pinnata* (pink, Hawthorn scented), *B. serrulata* (deep rose), and *B. tetrandra* (pale purple), fig. 84.

Boronias are readily increased by cuttings made from half-ripened wood or young shoots. When the latter are employed the plants from which they are obtained ought to be placed in gentle heat for a couple of weeks before the cuttings are taken, otherwise many of them will inevitably "damp" or decay at the base when placed for the purpose of propagation in a higher temperature than that in which the parent plants were growing. Insert the cuttings in sandy peat, surfaced with sand, using well-drained pots, covered with a bell-glass, and placed in a temperature ranging between 55° and 60°. When water is required, immerse in a water tank without removing the bell-glass. If all go well, the cuttings will root in a few weeks; the points should then be removed, and the potting be deferred till young growths have formed—use pots known as thimbles for the first potting, and plunge these in cocoa-nut fibre refuse in a cool house, and subsequently place in larger pots. When the cuttings are formed of half-ripened wood in summer time, they will root if placed in a shady part of a cool house or pit, being of course covered with a bell-glass, or placed under a hand-light.

In order to obtain bushy plants repeated stopping should be practised till the end of May, then the shoots already formed must be allowed to grow at will, in order to become sufficiently well ripened to flower the following year. Boronias may be trained in standard form, but it takes a few years to obtain a good specimen. For this purpose select a few of the strongest plants before stopping has been done, place a stake in the centre of the pot, and train a single shoot as straight as possible, keeping all side growths removed till the right height has been attained, then remove the point of the shoot, and keep the resulting growths frequently stopped till a compact head has been formed. Do not, however, attempt to get too large a head in one season; let the last stopping be done early in June, so that the growths have time to ripen, not so much for the purpose of securing flowers, as to obtain strong breaks the following spring, as the important point to aim at in growing standards is first to obtain a vigorous plant, then flowers will come freely the following year. Standards with 3 feet of clean stem and heads 18 inches in diameter are ideal specimens, which the cultivator should strive to produce.

When the flowering period is over the stronger shoots should be cut back sufficiently to keep the plant in good form, both in the case of standards and bushes; and soon after young growths are showing freely transfer to pots two sizes larger, until they occupy pots as large as is desirable, then with careful watering and an occasional top-dressing plants may be kept vigorous for years. Some growers employ a compost formed of fibrous peat and loam in equal parts, but I prefer good peat alone, as it keeps sweet and tough far longer than the best loam; a liberal addition of sharp sand and some charcoal ought to be used.

In July place the bush plants in cool pits, leaving the lights off entirely when there is no danger of heavy thunder storms. A deluge of rain falling on the plants should at all times be avoided; for this reason it is advisable to keep standards in a cool house throughout the summer, as pits seldom afford sufficient head room for them. After the bushes are housed in September, give all the air possible for a time, and throughout the winter admit it freely on all favourable occasions, giving just enough fire heat to prevent the temperature of the house falling much below 40°. In the matter of watering, Boronias require almost as much care as *Ericas*; but during the growing season, when the soil is packed with active roots, especial care must be taken to prevent the soil from becoming dust dry, or the young growths will wither at the points, and a short time after the leaves fall in shoals.—PLANTSMAN.

"FAMILIAR WILD FLOWERS."—The current issue of this work comprises plates and letterpress of the Bugle and Tall Fescue Grass, Ivy-leaved Toad Flax, the Spear-plume Thistle, Marsh Marigold and Daisy, Agrimony, the Bird's-foot Trefoil, White Campion, Daffodil, Brooklime, and Tufted Vetch.

CEANOTHUSES.

AMONG the great variety of hardy and half-hardy flowering shrubs suitable for the open border or for walls, none is more deserving of recognition than some of the numerous varieties of the *Ceanothus*; yet they are comparatively little grown, probably owing to the idea that they will not withstand our ordinary winters without protection. Such, however, does not apply to *C. azureus*, *C. Veitchianus*, and *C. Gloire de Versailles*, more especially the two latter, and the former only requires a more sheltered position and a little protection during severe frosts. I have a vivid remembrance of my first acquaintance with *C. azureus*, which was planted upwards of fifty years ago by my late father, against an open wall about 8 feet high, in South Warwickshire, facing south-east, but there was also a still higher brick wall opposite about 12 yards distant, which no doubt assisted in sheltering it from the cutting winds; no other protection, however, was ever afforded. The plant grew luxuriantly and flowered profusely annually, and its beautiful pale azure coloured inflorescences were most attractive. If I recollect aright the specimen in question became *non est* many years ago owing to its rampant growth being unsuitable for the position.

I am, however, somewhat consoled for its loss by the existence of a fine specimen each of *C. Veitchianus* and *C. Gloire de Versailles*, growing in

FIG. 84.—BORONIA TETRANDBA.

the grounds of two of the leading residents about a quarter of a mile distant, and I have the privilege of enjoying an inspection of them almost at any time. The former has been in position for several years against the gardener's cottage, and is a large plant growing vigorously and flowering profusely every season. The site is fairly sheltered from the north-east winds, and the aspect southerly. Beautiful as it is I have a prejudice in favour of my old love, with its more elongated and graceful racemes, also less rigid habit of growth of the branches. The other specimen in question, growing in the adjoining grounds, occupies a totally different *locale*, being in a border or bed, occupied by such other plants as *Azaleas* and dwarf *Spiræas*, in a position somewhat sheltered from the direct north-east winds, and where it is thriving apace, its beautiful pale blue flowers last summer affording a unique bit of colour in contrast with the surrounding hardy herbaceous flowers and ornamental shrubs. Of *C. azureus*, however, I do not know a specimen in the neighbourhood of Birmingham growing without glass protection, it evidently being more tender than its congeners alluded to. There are several other varieties worthy of cultivation.

In addition to the foregoing there was a collection of varieties of continental origin, grown at Chiswick, and raised, I believe, by the late Monsieur Vieter Lemoine, but I do not recollect if there was any published official report of the trials with them. I was informed that they were seedlings apparently of the *Gloire de Versailles* type, but with marked differences in the character of their robustness of growth, foliage

and colour of their flowers. I understood that they were planted in the open air in the spring and lifted in the autumn for housing during the winter, a pleasing feature being their proclivity to bloom in the young state. In referring to an old notebook I find the names and description of a few of the best varieties of the seedlings in question copied from either the *Journal of Horticulture* or one of its contemporaries, and which may be interesting to transcribe here, with a view to eliciting further information of either or any of those seedlings.

One of the best was *Sceptre d'Azur*, having large and very fine spikes of pale blue flowers—an improvement on *Gloire de Versailles*, fine, free, and a vigorous grower. The darkest of all in the blue flowered section was *Firmanent*. *Gloire de Varte*, also blue-flowered, was dwarf in habit, but very fine, free, and good. *Léon Simon* was of a delicate blue shade, a good grower, and very free. *Margardoule Andusson*, of a pretty and pleasing lavender-mauve hue, was very desirable. *Bleu Céleste*, the dwarfest of all, should have made a pretty pot plant. *Celestial*, a later flowering variety, was of a deep blue colour. There were also several varieties with rose-coloured flowers and with a certain sameness of character, *Marie Simon* being one of the best, with pinkish flesh-coloured flowers, very pretty, free, and good; a decided novelty. *Le Géant*, a little paler than the foregoing, was commendable.

Here, then, provided the foregoing seedlings are still in existence, is presented by the old and new varieties a collection more or less worthy of extended cultivation for the embellishment of our gardens.—W. G., *Harborne, Birmingham*.

CALLAS.

SOME years ago the horticultural world was surprised and pleased by the exhibition at the Drill Hall of what was a great novelty, a yellow Calla; it was exhibited by Messrs. Low & Son, of Clapton, and was introduced, I believe, by Mr. White, of Pentland Lodge, and was at once considered a great acquisition. It was not, as is sometimes the case in these variations, a washed out colour, but a brilliant yellow. We have all been familiar with the beautiful white *Arum*, *Richardia* or *Calla*, whichever people might wish to call it; and I think probably if the yellow one had been introduced first, and the white one afterwards, it would have received as much honour. There is another of nearly equal merit called *Elliotiana*, but I think most persons would prefer the plain leaves of the former one to the latter. My object in writing about them is, not so much to give information as to obtain it. I was so delighted with the plant that I committed the extravagance of procuring one from Messrs. Low, being informed that it required about the same treatment as what is erroneously called "*The Lily of the Nile*"—I say erroneously, because I do not think the white *Arum* grows as farth north as the Nile; it occurs nearer to the Cape, where I am told some of the valleys are white with it in the flowering season.

The yellow forms, I believe, occur in the Orange Free State and the Transvaal, where they are found in considerable abundance. I was, however, very unfortunate with my plant; it grew and threw out an offset, which I gave to a friend whose greenhouse is kept warmer than mine, but neither of the plants survived a second year. On mentioning it to some horticulturists they said it was a mistake to suppose it would endure the same treatment as the white *Arum*, that it required more heat, and I was therefore the more startled when I read that an admirer of the flower is about to try it in the open (of course, during the summer), and am anxious to know what treatment it really requires. And here let me say that oftentimes the answers to such questions are given by persons who have all means and appliances at their disposal, and are therefore not applicable to those of limited means. What is the use, for instance, of telling anyone of this description that hot-water pipes should be run through the tanks where aquatics are planted, when he cannot afford to have such things? Can these yellow Callas be grown in an ordinary greenhouse? and if so, what is the treatment they require?

Some years ago there were introduced two forms of the white *Arum* which were dwarf in character with small flowers, and were likely to be very useful as ornamental plants for the greenhouse; one of these was *Little Gem*, the other was called *nana compacta*; the former was very dwarf indeed, and was raised, I believe, somewhere in the Channel Islands, the foliage was not more than 3 or 4 inches, and the flower did not rise more than 6 inches above the pot. With this I have been entirely unsuccessful, it grows well and throws out a quantity of offsets, but I cannot get it to flower; I have let some grow at their will and throw out what offsets they like; others I have put into small pots and not allowed offsets to grow, but in neither case have I been able to procure flowers. The other, *nana compacta*, has behaved very differently; it is not so dwarf as *Little Gem*, the flower stem rising about a foot or 15 inches, the flower is about one-third of the size of the ordinary white *Arum*; it, too, increases rapidly, and a few plants of it scattered about my small greenhouse are very ornamental.

Both of these forms are, I believe, simply what we should call sports or variations, such as occur in many cultivated plants oftentimes in a very opposite direction. Thus we have very dwarf varieties of *Roses* throwing out shoots of very great length, from which have been derived some of our best climbing flowers; as in the home-raised variety of climbing *Devoniensis*, which is, as is well known, a sport which, instead of having only a few inches of growth, will oftentimes send out shoots of 15 or 20 feet long, while the flowers produced are quite equal to those of the parent plant; and so again with the climbing *Niphetes*, which does very much the same, and is one of the most attractive of our *Roses* for covering a wall.

But I have wandered from Callas, and now merely return to them to say I hope that some kind friend will give me the information I require; for if I were to get something reliable I should, although I have lost my plants, try to replace them. One sees these yellow ones constantly exhibited in the Drill Hall, and it makes one somewhat envious when admiring their beauty.—D., *Dcal*.

NOTES FROM ROWLEDGE.

A FINE WINTER STOCK.

I SAW in a couple of large span houses the other day at Rowledge, no less than from 9000 to 10,000 plants of the beautiful pure white wall-leaved Stock, *All the Year Round*. Apart from the fact that every plant being in bloom, the house presented a mass of snowy whiteness, there was a marvellous body of perfume emanating from the flowers that seemed to be at the first almost overpowering. The plants were in fours or fives in large 48-sized pots, and had been in bloom from October all through the winter. The proportion of doubles was marvellous, being really over 80 per cent., many pots having all doubles. This is a tribute to the merit of home-saved seed, for the variety has been thus grown for some eight or nine years. For cutting through the winter few plants could excel this Stock. It merits universal culture.

CUCUMBERS.

Few growers of Cucumbers, probably none, excel Mr. S. Mortimer as a producer of fine straight handsome fruits, or in greater abundance. The real test of productiveness is found in plants that carry all their fruits for seed, less, of course, a few that may not be properly fertilised, or be otherwise cut for eating. Mr. Mortimer grows for seed production generally, and anyone looking into his houses now, where such fine varieties as *Suttons' Al*, *Improved Telegraph* (a marvellous cropper), *Matchless*, *Success*, *The Keeper*, and others, would find the plants growing in narrow ridges of soil 20 inches across, and some 8 to 9 inches deep in the centre, kept in place by boards on each side 7 inches deep. The plants are about 20 inches apart. In this way, with root room restricted, and where top-dressing and feeding can be done, not only are wonderfully fine crops produced, but fruits that must rank among the handsomest in the kingdom.

TOMATO WINTER BEAUTY.

This is the designation of a new variety of Tomato, of which Mr. Mortimer presented, at the Drill Hall meeting on April 18th, to the Fruit Committee such a large number of fine ripe fruits, and obtained for it an award of merit. A few days since I saw the variety in bulk, growing in a long low span house. The plants were those that had furnished the fruits shown on the 18th ult. These plants were in 10-inch pots, and standing four deep on each side of the house, and were in every instance so true as to be exact duplicates of each other—stout, sturdy, and so dwarf that the heights ranged from 20 to 24 inches. On the top of each plant was a big cluster of very fine fruits, each cluster being probably 3 lbs. in weight. The sample—even inferior to that shown on the 18th, for the finest fruits of the early batch had been gathered and shown previously—gave many so handsome as to be equal to the well known *Perfection* form. All were of a very heavy description, being as solid as fruits well can be. The first plants were raised from a sowing made quite early in November, the present one being from a sowing made towards the end of the month. All were placed in the fruiting pits early in January. Temperature during the winter ranged from 55° at night to 75° on sunny days. The appearance of so many plants in fruit in this way was a remarkable spectacle, and could not probably be equalled anywhere so early in the season, or by any other variety. *Conqueror*, raised at the same time, and grown under the same conditions, was far excelled by *Winter Beauty*. The fine set of fruit was produced by tapping the Bamboo canes supporting the plants daily.—A. D.

HIPPEASTRUMS AT CHELSEA.

THESE gorgeous flowers have been very fine again this season at Messrs. Jas. Veitch & Sons' nursery at Chelsea, and the house devoted to their culture presented a bright display on the occasion of a recent visit. But one has to examine the flowers themselves to see their individual merit. The firm has long been celebrated for the *Hippeastrums*, and judging by the specimens seen, an immense amount of care and attention has been bestowed upon the crossing or hybridising, for chance work would not have brought about such results. The operator has to keep in view not merely the variation in colouring, but the form and substance of the flower. Anyone who is in the habit of crossing these plants knows perfectly well the inclination to run back, as it were, and produce narrow segments, especially the lower one—such forms were almost absent in the Chelsea house. One would hardly give the Chelsea atmosphere credit for producing such healthy foliage.

To give a detailed description of all the good varieties seen would occupy too much space, so I shall content myself with noting the cream of the varieties. *Pythion* was the first to attract attention; it is a deep crimson. *Raphand* is rosy crimson, with white central veins. *Talaus*, a bright orange red, feathered and veined with white, is an attractive flower. *Ira*, another orange of a deeper shade, with a creamy white ground and veins, is of great substance. *Etis*, rich glowing crimson, is a perfect flower, as is *Tarasco*, crimson veined with a deeper shade.

Cythera is another rich crimson of capital substance, while Frusino is a bright red with green veins and throat; very large. Aradus is a fine circular flower, with a creamy white ground, heavily netted and veined with rose.

Camis, deep orange red with a green base, and a large crimson spot at the base of each segment, is distinct, as is Cupid, a rosy flushed flower edged with white. Lago is deep glowing crimson of fine shape and substance. Dunird is another good crimson with a green base. Belus, a fancy variety with a creamy white ground slightly veined with rose, is very attractive, while Eurytus, a light flower, is flushed with rosy crimson. Hylia, a white ground, is veined with rosy crimson.

Most of these seedlings were flowering for the first time, so that none of them is likely to degenerate, but, on the contrary, should improve with another year's growth. I think the firm is to be congratulated on the nomenclature, for while the names are quite distinct, they are short, and such as fasten on the memory without an effort.—J. B. R.

ROYAL HORTICULTURAL SOCIETY.

DRILL HALL.—MAY 2ND.

THOUGH at first sight the Drill Hall presented a somewhat patchy appearance, there was really an excellent display from numerous exhibitors. Narcissi were superb, and the same may be said of the Irish Tulips. Fruits were not very numerous, but the vegetables from Mr. Wythes attracted much attention. Orchids were comparatively scarce.

FRUIT COMMITTEE.—Present: P. Crowley, Esq. (in the chair); with the Rev. W. Wilks, and Messrs G. Bunyard, E. Shaw-Blaker, W. Poupert, A. F. Barron, T. J. Saltmarsh, A. H. Pearson, J. Wright, A. Dean, S. Mortimer, W. Bates, P. C. M. Veitch, G. T. Miles, G. Wythes, H. Balderson, F. Q. Lane, J. Smith, and W. Gleeson.

Mr. G. Wythes, gardener to the Duke of Northumberland, contributed an excellent collection of vegetables, which comprised London Lettuce, good Prickly Spinach, Little Gem Cabbages, Veitch's Model Carrots, Record and Syon Maincrop Lettuce, Syon Early Potatoes (a fine sample), Broccoli Late Queen, Sutton's Continuity, Veitch's Model, Miller's Late Dwarf, and Cattell's Eclipse, all of first-rate quality, size, and colour; Mushrooms, Tomatoes, Sprouting-Broccoli, both the purple and white forms; Endive, French Beans Ne Plus Ultra and Early Favourite in pots; also Peas growing in pots, with Seakale, Turnips, Cucumber Veitch's Perfection, Curled Kale, and salading in great variety—a truly noble exhibit for such a season.

Mr. O. Thomas, gardener to her Majesty, Windsor Castle, sent an exhibit of Peas and Tomatoes; the former were well podded examples of Harbinger and a Tomato named The Epicure, a seedling between Frogmore Selected and Sutton's Dessert, it partakes of the latter variety more than the former, the fruits being rather small but well coloured, and the bunches exhibited contained seven to eight fruits. Mr. J. Fitt, gardener to F. W. Campion, Esq., Colley Manor, Reigate, sent a box of Royal Sovereign Strawberry; the fruits were large and well coloured. Mr. J. Ryder, gardener to the Countess of Limerick, St. Albans, exhibited four dishes of Peach Alexandra, which were of good size and well finished. Mr. S. Mortimer, Rowledge, Farnham, again sent boxes of his new Tomato Winter Beauty; the fruits were large and well coloured.

A letter to the Council from the Customs authorities was read referring to the importations of all kinds of fruit, all of which, including Grapes, being expressed by hushels, and it suggested that some other denominators would be advisable. After some discussion it was resolved to ask the Council to form a small Sub-Committee from the Fruit Committee to consider the matter, and to take such advice as would assist in arriving at a decision.

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair); with Messrs. J. Fraser, O. Thomas, C. T. Druery, H. B. May, R. Dean, W. Howe, J. Jennings, J. F. McLeod, R. B. Lowe, C. J. Salter, C. E. Shea, H. S. Leonard, J. W. Barr, Chas. Jeffries, G. Gordon, F. D. Pawle, E. H. Jenkins, H. J. Cutbush, E. Beckett, E. T. Cook, H. J. Jones, G. Paul, and E. Mawley.

The most fragrant, and probably to many visitors the most attractive exhibit in the Hall on Tuesday, was comprised of Canterbury Roses from Mr. J. Mount. In all there were six boxes of cut blooms, with trusses on long stems between. These were remarkable for the excellence of the flowers and foliage, and the stoutness of the wood. Amongst the most beautiful were La France, Mrs. W. J. Grant, Susanne Marie Rodocanachi, Catherine Mermet, Ulrich Brunner, Madame Mozart, Crimson Rambler, Captain Hayward, Mrs. John Laing, and Caroline Testout. Messrs. Hogg & Robertson, Dublin, sent a large display of Irish grown Tulips. There were single and double Dutch varieties with many species, and Darwinian types. The flowers throughout were of splendid quality, and of rich colour, but they would have produced a better effect if some green leafage had been used as a groundwork.

Messrs. Geo. Jackman & Son, Woking, exhibited an interesting display of spring flowers, comprising the double flowering Cherry, *Pyrus malus floribunda*, *Mespilus canadensis*, and *Cytisus præcox* in the shrubs, while a pretty box of *Primula Sieboldi* in a variety of colours, *Gentiana acaulis*, *Adonis vernalis*, *Anemone fulgens*, and boxes of *Magnolias grandiflora*, *conspicua*, and *Soulangeana* were very attractive, as were also a couple of boxes of rock and alpine plants. Messrs. Paul & Son, Cheshunt, exhibited an attractive group of Roses in pots. The climbing Rose, "The Dawson," with its rosy pink flowers and bright foliage, formed part of the exhibit. The specimen plants in pots presented a

very healthy appearance. Mavoureen, Ulrich Brunner, Paul's Early Blush, Innocente Firola, Beauté Inconstante, Caroline Testout, Rev. Alan Cheales, Elise Fugier, and Clara Watson were all in fine form, and contributed to the display.

Messrs. H. Cannell & Sons, Swanley, staged a basket of the well-known Primrose Miss Massey, a very fine variety, with deep crimson flowers and a bright yellow eye. Mr. E. Hill, gardener to Lord Rothschild, Tring Park, Tring, sent a small group of the yellow Arum, *Richardia Pentlandi*, with blooms very rich in colour. Mr. Jas. Douglas, Great Bookham, staged a good collection of Auriculas, the foliage and flowers being very attractive. The varieties were Elegant, Minerva, Byron, Firefly, Urania, Friendship, Florence, Boadicea, and Mrs. Markham.

Mr. H. B. May, Upper Edmonton, contributed an interesting exhibit of *Gleichenias* in thirteen species and varieties, such as *rupestris gigantea*, *speluncea*, *Mendeli*, *rupestris glaucescens*, *flabellata*, *Backhousiana*, and *longipinnata*. Needless to say, all the plants were well grown and effectively staged, with a groundwork of *Adiantums* and *Selaginellas*; also a few plants of the Crimson Rambler Rose, in 5-inch pots, beautifully grown, and covered with flowers, showing its value as a decorative plant. Mr. G. W. Piper, Uckfield, again exhibited his Tea Rose, Sunrise. It is a charming variety, and one that will be very popular; but the receptacles used on this occasion did not enhance the beauty of the flower. Messrs. J. Hill & Son, Edmonton, arranged an interesting collection of *Aspleniums*. They were very attractive, and included such forms as *Colensoi*, *biforme*, *inæquale*, *bulbiferum*, *Belangeri*, *Nidus*, and *laxum pumilum*.

Messrs. J. Veitch & Sons, Royal Nurseries, Chelsea, exhibited a box of Java *Rhododendrons*, which comprised the noted hybrids of the firm, such as *balsaminæflorum roseum*, *b. album*, *b. carneum*, *b. Rajah*, and *R. aureum*; also a beautiful *Croton*, Mrs. Ice-ton. Mr. J. T. Gilbert, Dyke, Bourne, Lincoln, staged some good specimens of Crown Imperials, very bright in colour; also some *Anemones*. Mr. J. Fitt, gardener to F. W. Campion, Esq., Colley Manor, Reigate, staged a collection of seedling *Polyanthuses*, which represented a wide range of colours and markings; also a fine bunch of double yellow Wallflower, *Cheiranthus luteus plenus* of a capital type.

Messrs. W. Cutbush & Son, Highgate, staged an interesting group of spring flowering plants. The *Ericas* were very fine, especially such forms as *E. Cavendishi*, *E. Spenceriana*, *E. erecta* (beautifully flowered), *E. candidissima*, and *E. hybrida*. The *Boronias* were also very bright. The well known red *Epiphyllum Gartneri*, and an *Azalea indica* named Chicago, were also worthy of note.

NARCISSI COMMITTEE.—Present: J. Bennett-Poë, Esq. (in the chair); and Miss Willmott, with Messrs. Jas. Walker, R. Sydenham, W. Goldring, S. Bourne, G. Titheradge, G. Engleheart, J. Pope, A. Kingsmill, P. R. Barr, and C. Scrase Dickens.

Messrs. Jas. Veitch & Sons, Chelsea, staged a large display of Daffodils tastefully arranged between small Ferns, a method some of the other exhibitors might copy with advantage. The popular Sir Watkin was in fine form; Glory of Leiden, with its bright yellow tubes, was attractive, as were also such forms as Madame de Graaff, *bicolor grandis*, Emperor, Sulphur Phoenix, Queen of Spain, F. W. Burbidge, with a beautifully fringed tube; Horsefieldi, Orange Phoenix, Leedsi Circe, *L. amabilis*, Ivanhoe, Queen Anne's Jonquil, and the beautiful Queen of Spain.

Messrs. Thos. S. Ware, Ltd., Tottenham, contributed a large display of spring flowers. The majority were Daffodils, which made a capital group. The most conspicuous forms were N. Victoria, an immense form, Sir Watkin, maximus, Barri conspicuus, Leedsi Gem, a very chaste form, Empress, Emperor, Sulphur Phoenix, Orange Phoenix, and Wm. Goldring. The other plants were a good strain of Alpine Auriculas, Muscari, *Primula Sieboldi* in variety, *Polyanthuses*, and a collection of alpine and rock plants.

Messrs. R. H. Bath, Ltd., Wisbech, staged a good collection of Narcissi, beautifully sprayed with their own foliage; the flowers were very bright and fresh looking. The chief forms were Victoria, Grandee, Queen of Spain in grand form, Captain Nelson, Weardale Perfection, Sulphur Phoenix, Madame Plomp, Gloria Mundi, Madame de Graaff, very pure in colour, and maximus.

Messrs. Barr & Sons, Covent Garden, had an extensive display of Daffodils. The varieties and species most noteworthy were Madame de Graaff, Glory of Leiden, Ladas, Gloria Mundi, Weardale Perfection, Apricot, a remarkable colour, J. B. M. Camm, Emperor, W. Wilks, Mrs. Bateman, Princess of Wales, Barri conspicuus, poeticus poetarum, and Leedsi Beatrice; also Muscari, Tulips, *Erythronium Pink Beauty*, very attractive; and a small collection of rock plants.

Mr. Downes, gardener to J. T. Bennett Poë, Esq., Cheshunt, staged a very graceful display of Daffodils well displayed. The most noteworthy forms were Emperor, Madame de Graaff, Nelsoni major, grandis, Mr. J. B. M. Camm, Mrs. Langtry, and Lulworth. The Rev. G. H. Engleheart exhibited a collection of hybrid and seedling Narcissi. The majority of them were really beautiful and very distinct. The best were Sequin, Aigret, Will Scarlet, Moonlight, Garnet, Marina, and Diadem.

ORCHID COMMITTEE.—Present: H. J. Veitch, Esq. (in the chair); and Messrs. J. O'Brien, H. Ballantine, de Barri Crawshaw, H. Little, J. Gurney Fowler, A. H. Smee, H. J. Chapman, John Gabriel, W. H. Young, W. H. White, A. Outram, T. Statter, H. T. Pitt, E. Hill, T. W. Bond, J. Colman, W. Cobb, T. Mason, W. H. Protheroe, S. Courtauld, and W. Thompson.

Mr. W. H. White, Orchid grower to Sir Trevor Lawrence, Bart., Burford Lodge, Dorking, sent a few Orchids of considerable interest. There were *Cirrhopetalum Colletti*, *C. Cumingi*, *Pleurothallis ornatus*,

Masdevallia O'Brieniana, with Dendrobiums crepidatum, micans giganteum, stratius and Nestor. Messrs. H. Low & Co., Bush Hill Park, Enfield, contributed a collection of miscellaneous Orchids, in which Cattleyas were conspicuous. W. Cobb, Esq., Tunbridge Wells, sent Odontoglossum triumphans, Dulcote var., and Cypripedium Goweri magnificum. Mr. F. Burton, Gainsborough, showed Cypripedium porphyrites, a hybrid of which the parentage is unknown. Mr. W. Stevens, gardener to W. Thompson, Esq., Walton Grange, Stone, Staffs, sent some superb Odontoglossums, including polyanthum giganteum, excellens luteum, luteo-purpureum, sceptrum Stevensi Ruckerianum ocellatum, with one or two varieties of crispum and Lælio-Cattleya Hyppolyta aurantiaca.

Mr. S. Cook, gardener to de Barri Crawshay, Esq., Rosefield, Seven-oaks, was represented by a collection of Orchids, mainly comprising Odontoglossums. Of these the most conspicuous were Ruckerianum Rosefieldensis, triumphans Rosefield Emperor, Andersonianum Raymond Crawshay, A. Miss de Barri Crawshay, and nevadense. Mr. Bond, gardener to C. L. N. Ingram, Esq., Godalming, sent Lælio-Cattleya Sir Wm Ingram, and Mr. J. McBean, Cooksbridge, Odontoglossum excellens McBeanianum. Mr. H. J. Chapman, gardener to R. I. Measures, Esq., Camberwell, showed Cypripedium Thyades. Messrs. J. Veitch & Son, Ltd., Chelsea, staged Epidendrum elegantulum luteum, and Dendrobium crepidato-nobile. There were one or two other exhibitors of Orchids.

AWARDS.—Fruit Committee: Silver-gilt Knightian medal to Mr. G. Wythes, V.M.H. Orchid Committee: Silver Flora medal to de Barri Crawshay, Esq., and Mr. W. Stevens; and silver Banksian medals to Messrs. W. H. White and H. Low & Co. Narcissus Committee: Silver-gilt Flora medal to R. H. Bath, Ltd.; silver Flora medal to Messrs. Barr & Sons; and silver Banksian medal to T. S. Ware, Ltd. Floral Committee: Silver-gilt Flora medal to Messrs. Hogg & Robertson; silver-gilt Banksian medals to Messrs. H. B. May and Paul & Son; and silver Banksian medals to Messrs. G. Mount, G. Jackman & Son, and J. Hill & Son.

CERTIFICATES AND AWARDS OF MERIT.

Epidendrum elegantulum luteum (J. Veitch & Sons, Ltd.).—This is a charming flower with its bright yellow sepals and petals and a pure white lip (award of merit).

Narcissus Dorothy Kingsmill (A. Kingsmill).—A handsome variety of the large trumpet section. The perianth is white, and the long trumpet sulphur-yellow (award of merit).

Narcissus Cecily Hill (R. Backhouse).—This flower has broad creamy white perianth segments and a flat yellow crown edged with rich orange (award of merit).

Narcissus Hesperus (G. H. Engleheart).—This is a striking flower. The crown is very bright orange and the perianth cream (award of merit).

Narcissus Marina (G. H. Engleheart).—The segments are creamy, with a canary, very broad and open tube (award of merit).

Odontoglossum excellens McBeanianum (J. McBean).—A handsome variety. The yellow is very bright, as are the chocolate markings (award of merit).

Odontoglossum Andersonianum Raymond Crawshay (de B. Crawshay).—A very attractive form. The whole of the organs have numerous red spots on the cream ground save at the tips and at the margins (award of merit).

Odontoglossum Andersonianum Mrs. de Barri Crawshay (de Barri Crawshay).—This is a lovely Orchid. The sepals and petals are pale cream with occasional red spots. The lip is yellow with a large chocolate crimson blotch (award of merit).

Odontoglossum Ruckerianum rosefieldensis (de B. Crawshay).—The purple in this variety is very deep, and the spots effectively placed (award of merit).

Richardia (Calla) Pentlandi, Tring Park variety (E. Hill).—This is a superb variety of the richest yellow; the spathe is large sized with a reflexing edge (award of merit).

Richardia (Calla) suffusa (E. Hill).—The colour of this is soft cream with a deep purple throat (award of merit).

THE YOUNG GARDENERS' DOMAIN.

ASPARAGUS IN BEDS.

THE Asparagus is one of the choicest vegetables in cultivation, and it is grown, more or less, in every gentleman's garden. Not only is it valuable for outdoor culture, but also for forcing, and it is much appreciated when the young heads are sent to the table early in the year. When, however, it is produced in the open better heads and a sweeter flavour are insured. There are two methods of growing it outdoors. One is on a raised bed and the other on the level ground, and so far as my experience goes the former is much the better plan to adopt.

I had the good fortune to serve for five years under a very successful grower of Asparagus. We had six raised beds, occupying (alleys included) about 12 rods. Each bed was 4 feet wide, with 18-inch dividing alleys. They had been made upwards of twenty years, and the number of heads produced, year by year, during my term of service was wonderful. I am sure thousands must have been cut and taken to the kitchen each season, yet there was always an abundance of growth left to mature. The soil was of a rather light nature, though sufficiently adhesive to hold ample moisture. In the early spring about an inch of the surface soil of each

bed was raked off, so that the tender heads should have less resistance in coming through, and also that the warmth of the sun might more easily reach the plants. After this had been done a good sprinkling of salt was given for the benefit of the plants, and to help keep weeds in check. As the season advanced and the demand for supplies became greater the drainings from a cowshed were applied, afterwards giving a watering with clear water to cleanse the young growths. The beds were kept scrupulously clean from weeds by hand pulling, no hoe being allowed, as is sometimes the case. Several waterings with liquid manure were given during the summer.

As the autumn approached, and the growth reached maturity, the beds were thoroughly cleared. The ripened growth was cut off about 4 inches from the ground and burnt. Then the top soil, to the depth of the crowns (being careful not to injure them with the fork), was taken off and laid in the alleys; after which a good coating of farmyard manure was given and the soil replaced. In this operation the sides of the beds were chopped down, and made even and neat, as also were the ends. Our "chief" was very particular in having the sides straight, and as perpendicular as possible.

It was my privilege to assist in the work connected with the above mentioned beds (with the exception of making), and what I have here stated is as nearly as possible the way the work was proceeded with year after year. Our mode of cultivation may not correspond with others, but I consider it thoroughly good. I might mention that Lettuces were grown in the alleys—a row being planted down the centre. Thus as much space as possible was taken advantage of.—ASPIRANT.

WATERING.

I CONSIDER plant watering to be the most important operation done under glass. In some establishments youths are entrusted to do this work, and if a sharp eye is not kept on them woe betide four-fifths of the plants that come within reach of the waterpot. I would much rather see badly potted plants in the charge of a careful and competent waterer, than plants excellently potted in perfect compost under the care of an inexperienced youth. Very frequently plants that have been repotted are watered much too soon, which is a grievous error.

Let me give an illustration of my method of procedure. A short time ago I repotted several hundreds of Chrysanthemums that are intended to produce exhibition blooms, and I did not water them until eight days after, the syringe only being used. The plants were watered the night prior to their transference from 60's to 32-sized pots, and the soil used was just moist enough to handle without stickiness.

To emphasise my meaning I will quote another illustration of good and indifferently watered plants. I once saw a splendid collection of Bouvardias and Euphorbia jacquiniæflora deluged with water immediately after being repotted to 5-inch pots in July. The weather was somewhat dull and cold at the time, and the plants were in unheated frames—the only place available at the time. The result, of course, can easily be imagined. The new soil was so saturated that the roots refused to enter it. The plants lingered through the autumn, but refused to grow even when given a more genial temperature. They were an eyesore, and splendid examples of mismanagement.

On Sundays the watering is often scamped, and the plants have to pay the penalty. In some gardens the whole of the watering and syringing is done on this day by the duty man, the plants being probably heavily watered on Saturday afternoon to lighten Sunday work. The best method I have found is for each man to water his own charge on Sunday as on weekday mornings. The work comes much lighter for the duty man, or men, if the glass is very extensive. At one period I had a journeyman under me who was a very "dry waterer," if I may be permitted to use such an expression, and he was particularly afraid on Sunday mornings to give them too much "lotion," as he called it. He was watering at the time some bush Chrysanthemums, walking along the rows, and just giving each plant something less than half a pint, until I stopped him. This method of watering cannot be too strongly condemned, as it often deceives a practical man.—FOREMAN X.

FUCHSIAS.

FUCHSIAS are among the prettiest plants that are grown, as, although they are not very valuable for cut flowers, they have a grand appearance when covered with blooms. To obtain early cuttings, the old plants should be started at the beginning of the year, with a temperature of 60° to 65° at night, 65° to 70° by day; lightly syringe the plants twice daily with tepid water when the weather is bright, doing it early enough for the plants to become dry towards night. When the growths are about an inch in length they should be taken off so that a little of the old wood will be attached to them; carefully trim with a sharp knife, and insert around the sides of small 60's, about five in each pot, in a compost of equal parts of loam, leaf soil, and sand; give a watering, and plunge the pots in cocoa-nut fibre refuse in a house with a temperature of 65° to 70° at night, 70° to 75° by day, keeping them rather close for a few days.

When the cuttings are well rooted pot them singly in thumb pots, using a similar compost to that advised for the cuttings, give a watering, and afford them the same temperature. As the plants begin to grow and the roots take hold of the soil they should be removed to a cooler house with a night temperature of 60°; syringe them twice daily when the weather is bright, as this will keep thrips and green fly in check. When they have a fair amount of roots transfer them into 5½-inch, clean, well-drained pots, using a compost consisting of three parts loam, one leaf soil, and one sweet horse droppings, with enough sand to keep it porous, and a little of Thomson's Vine manure well incorporated. The plants should not be potted too deeply, but make the soil firm around them, place a neat

stake to each, and afford a temperature of 60° at night; keep the house rather close for a few days until root action has recommenced.

As the plants again begin to root they should be stopped if for bush plants, but for pyramids this must not be done until they have reached the desired height. When the plants are well rooted remove them to a house with a temperature of 50° to 55° at night, 55° to 60° by day. Do not in any way neglect the syringing at this stage on bright days. A little weak liquid manure will now be found beneficial to them, and as the plants gain vigour apply it stronger. Attend to the tying and stopping of the side growths when needed, as this will make compact plants; stopping twice will be sufficient unless they are required for late flowering. If old plants are potted and neatly tied they make a grand show if stood outside during the summer.—P. R.

FRUIT FORCING.

Vines.—*Early Houses.*—The Vines started at the new year have the Grapes in an advanced stage for ripening; some are commencing to colour, and will need a circulation of warm, rather dry air. An arid condition of the atmosphere, however, must be avoided, inasmuch as it is sure to induce an attack of red spider. It is imperative to keep the foliage clean and healthy for as long a period as possible. Where red spider has obtained possession prompt measures must be taken for its destruction. Recourse is sometimes had to the syringe, which, even when the water is clear and soft, is apt not only to more or less damage the bloom of Grapes advanced in colouring, but to leave a deposit on the berries greatly detracting from their appearance. Sponging the leaves is a safe means of preventing the spread of the acari, and taken in hand on the first appearance of the pests is not as tedious as it seems.

Houses of Ripe Grapes.—The earliest Vines have ripened their crops somewhat earlier than usual, are well coloured, and of excellent quality. Maintain a circulation of air, and allow the temperature to fall to 60° at night. The soil must be kept healthfully moist, so as to keep the foliage in good condition. Moderate air moisture is also essential to prevent the foliage prematurely ripening, and it benefits rather than prejudices the keeping of the Grapes, provided the air is not stagnant. The Grapes are liable to lose colour with hanging; a slight shade will be beneficial in helping to retain colour, especially in Black Hamburgh and Madresfield Court. A double thickness of herring netting, or a single thickness of pilchard netting, placed on the roof-lights is sufficient. It is also desirable, where it can be practised without crowding the principal leaves, to allow a moderate extension of the laterals, which will tend to promote root activity, and assist the Vines to recuperate their exhausted energies.

Muscats.—The Vines started in December and brought forward gently in the early stages are now beginning to colour. Muscat of Alexandria takes longer to colour than Madresfield Court and Black Muscat (Muscat Hamburgh), and the berries of Muscat of Alexandria are liable to shrivel unless the Vines are well supplied with water and nourishment at the roots. When these are provided a much drier condition of the atmosphere may be allowed than is otherwise safe, and it is absolutely essential to good finish in Muscats, for when in a saturated atmosphere there is danger of "spotting," and what is gained in size is lost in colour and quality. Directly the Grapes change colour give a thorough supply of water or liquid manure, following with a mulch of sweet, rather strawy material, a couple of inches thickness sufficing, and being dry it will prevent too much moisture arising, whilst keeping the soil moist. Muscat of Alexandria is liable to have the upper berries of the bunches scorched by the sun when the Grapes are ripening, which is due to the sun acting powerfully on the epidermis, whilst, perhaps though imperceptibly, covered with moisture. As a safeguard against scorching a slight shade should be provided, ventilating early, and increasing the air with advancing sun heat, but allowing a high temperature by that means. A little more time is required with the shade, but it well repays the outlay, as the losses from scorched Grapes are sometimes considerable where the panes of glass are large and when the weather is bright.

Muscats in flower set freely with a night temperature of 70°, 75° by day, and 80° to 85° or 90° with sun heat, always with a circulation of air. The points of the bunches should be kept well up to the light. When the caps of the flower are being cast, it is advisable to rap the bunches lightly, better still to gently go over each bunch with a camel's-hair brush and follow soon afterwards, or when the caps are off, with another brush laden with pollen taken from such free-setting varieties as Alicante, Black Hamburgh, and Foster's Seedling. The influence of foreign pollen is far more potent, and secures finer berries than impregnation of a variety of Grape or other fruit with its own pollen, which is often inert from continued in-and-in breeding.

Succession Houses.—Follow up the thinning of the bunches and berries, also tying, disbudding, stopping, and regulating the growths. Allow crops proportionate to the vigour of the Vines, and retain as much foliage as can have full exposure to light. Examine the borders at least once weekly, and when dry water freely, assisting those in full foliage and

carrying heavy crops with tepid liquid manure or top-dressings of fertilisers washed in moderately, mulching with an inch or two thickness of rather lumpy sweet manure. Well-drained inside borders will take almost any amount of water after the Vines are in full foliage, it having a hygienic as well as a moisture-supplying effect. Excessive watering, however, causes a soddened and sour condition of the soil which commonly results in shanking and bad finish. Ventilate early, it assists accumulated moisture to disperse, gives texture to the foliage and firmness to the wood, besides securing a full amount of stored matter. Allow a high day temperature from sun heat, closing early, alike to push ahead the crop and to store the sun-warmed atmosphere. At night a temperature of 60° to 65° is best, especially for Vines carrying heavy crops.

Late Houses.—Disbudding, also tying and stopping the growths, must be attended to as they become sufficiently advanced. Every advantage of sun heat should be taken to increase the ventilation early in the day, and of closing early in the afternoon, as a means of securing a long day's work, and of vigour and health in the Vines, dispensing with fire heat as much as possible, yet employing enough to keep the Vines in steady progress. Make selection of the bunches that are to remain for the crop, large ones, especially loose, being the worst for finish, and the medium-sized and compact the best for perfecting properly and keeping. Crop lightly rather than heavily, and apportion the crop to the vigour and variety of the Vine.

Late Hamburghs.—These and other summer Grapes will have started naturally, and require disbudding, tying down, and regulating, not leaving more growths than can have space for the full expansion of the foliage. In stopping allow two, preferably four, joints of growth beyond the show of fruit, and pinch the laterals below it to one joint as made, but above the bunch allow them to extend so as to insure an equal covering of the space with foliage that can have exposure to light; afterwards keep them pinched to one leaf as new growth is made. Where the space is restricted closer stopping may be practised, not allowing the laterals to interfere with the principal leaves. Ventilate early and freely so as to insure short-jointed stout wood and thick leathery foliage. Avoid a saturated condition of the atmosphere, yet a genial state must be provided by syringing the borders, walls, and paths in the morning and at closing time. Have the borders properly moist, yet avoid saturating them, and encourage surface roots by a light mulching of lumpy material.

THE KITCHEN GARDEN.

Borecole.—It is not yet too late to sow seeds of Borecole, though the most productive plants are raised and finally planted earlier. The seeds of Buda or Asparagus Kale may be sown during the next month or so thinly in drills 18 inches apart, where the plants are to remain, eventually thinning them to about 6 inches apart in the row. Thus treated excellent crops will be had next spring.

Broccoli.—Where space is limited and the ground has to be kept closely cropped, late raised Broccoli plants are the most reliable, not having time to become leggy before the ground can be spared for their reception. Sow the seeds in a sunny open position, either in drills 5 inches apart or broadcast. In showery weather dust over the young plants occasionally with soot and lime to save them from slug. Early raised Veitch's Autumn or other popular early Broccoli ought to be finally planted 24 inches to 30 inches apart on good ground before they weaken each other in the boxes or nursery beds in which they are pricked out. A pinch of seed may be sown with a view to having late plants for storing in pits next autumn.

Cauliflower.—Plants of Snowball and its synonyms in pits and rough frames should not be hard forced. Draw the lights off them on warm bright days, closing moderately early, and protecting with mats or litter on cold nights. When the hearts commence forming feed liberally at the roots. Treat those in hand-lights similarly. Plant successional stock at the foot of sunny walls and on warm borders in rich soil. The autumn-raised plants of Autumn Giant that are wanted to produce extra fine hearts next August should be put out on rich ground, and allowed plenty of room.

Cabbage.—If the breadths of Cabbage are not making such rapid progress as is desirable, draw soil up to the stems, and in the furrows thus made pour strong liquid manure. Or, if the weather is showery, sow nitrate of soda, at the rate of 1 oz. to the square yard, among the plants. Commence-cutting directly some of the hearts are fit, not waiting till they are hard, and from the stumps left good successional heads will result. Red or pickling Cabbage should have a rather long period of growth. Plant on good ground directly the plants are large enough for the purpose.

Lettuce.—Plants of Cabbage and Cos varieties should be put out every fortnight or so. In hot dry weather Lettuce transplants badly, and from this date onwards the seed should be sown where enough plants are to remain to form good rows. The ridges between Celery trenches are excellent positions for summer Lettuces. Sow the seed thinly in shallow drills 10 inches to 12 inches apart, covering with fine soil. It is worthy of note that Lettuce succeeds well on the ridges just alluded to without any addition of solid manure, but will fail, or make poor progress, on the level unless the ground is heavily manured.

Tomatoes.—Old plants can be made to produce good second crops, but these rarely equal those obtained from young plants. Those, then, now carrying heavy crops, some of which are already ripening, should be kept free of superfluous growth, concentrating the strength of the plants on the crops they are producing, with a view to increasing their weight. Sow more seed in May, and prepare strong plants for producing heavy crops next autumn. Plants carrying two or three clusters of fruit require abundance of water, and frequent supplies of liquid manure. The roots

of Tomato plants revel in rich top-dressings, but it is a safer and better practice to provide a bed of soil or ashes underneath, for them to spread their roots into. Those plants newly top-dressed with rich compost must have water supplied to their roots nearly or quite as often as previously. Pinch or cut out all superfluous side shoots as fast as they form, and reduce the leaves in size where they are crowded only. A warm airy house best suits Tomatoes. Keep the hot-water pipes warm all through the night, give a little air early on warm days, opening the ventilators as the sun gains in power. Reduce the air gradually, but do not close early enough to box up much sunshine, or disease will soon follow.

THE BEE-KEEPER.

SEASONABLE NOTES.

THE changeable weather that has prevailed during the past month has been most disastrous to the bees. High winds, snow, hail, and rain have been general throughout the country. The temperature, too, has been below the average, which will account for the bees being confined to their hives for several days in succession. During the last fortnight of April, instead of the bright days which often prevail at this season, it has been dull, and altogether unfavourable for the bees to make much headway. Fortunately those stocks which received timely attention have advanced, though slowly; others that were left to chance appear to be no stronger than they were a month ago. This fact alone shows the advantage of attending to the requirements of the bees as often as necessary.

Warmth in the brood chamber is a necessity during the early spring months more than at any other season, and if the outside temperature is low steps should be taken to keep the interior of the hive as warm as possible. This can be done by placing some extra coverings on the top of the frames. Any warm material will have the desired effect, and should this not be conveniently to hand a good substitute may be found in paper. Place several thicknesses of paper on the top of the other coverings, then a piece of board, which may be weighted down with a brick. It is surprising the amount of warmth that may be obtained in this manner.

We cannot too strongly impress on bee-keepers the harm that is done by carelessly handling the bees at this season. The frames should not be uncovered, unless there is some definite object in view. Brood may be chilled in a very short time by lifting the frames out of the hive, and exposing it in a low temperature. Chilled brood, we are aware, is quite different from foul brood. But may not the latter pest be created by having a large amount of the former in a hive? We are inclined in this belief by observing foul brood in some districts where it was unknown previous to the introduction of the movable frame hive.

SUPERS ON HIVES.

In our previous notes we promised to revert to this subject again. It will be remembered, owing to the large amount of honeydew, much of the honey obtained last year was useless for commercial purposes. We therefore allowed several large supers to remain on the hives throughout the winter. The experiment was interesting, as showing what effect it would have on the bees. When examined in February, they were, without exception, in good condition. But contrary to our expectation we found that in the majority of the hives the bees were clustered between the frames in the body of the hive where there was little store left. We, therefore, decided to observe them closely in case they should suffer during a spell of cold weather in the spring.

During the past few weeks those stocks on which were single crates of sections and shallow frames were in better condition than those having full-sized frames in the supers. The only exception was in the hives where the bees had taken possession of the frames in the top storey, and had commenced brood-rearing there. This was what we expected, but we thought the majority of the colonies would have forsaken the lower frames so as to be nearer their stores. As this was not the case we placed them all in the bottom hive, the brood and the empty combs being placed in the centre of the hive, and some frames of sealed stores on the outside. A few square inches of the stores were uncapped. This had a stimulating effect on the bees. They were afterwards covered up warm as advised above. The uncapping of the sealed stores will be continued about every fourth day. This will have the desired effect, and should a change in the weather set in they will increase at a rapid rate; and although early swarms cannot be expected owing to the lateness of the season, they will doubtless give a good account of themselves when the honey flow comes.

If stocks are short of sealed stores continue to feed with thin syrup until natural supplies can be obtained from outside.—
AN ENGLISH BEE-KEEPER.

•• All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," 8, Rose Hill Road, Wandsworth, S.W., and NOT to 12, Mitre Court Chambers, Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *nom de plumes* are given for the purpose of replies.

Loose Gravel Path (O. F.).—Loose paths are very unpleasant, and we know of nothing but to secure some fine binding gravel and mix it with the present surface. This would not be a very costly proceeding; but perhaps you could not conveniently procure the article. Of course the rough stones can be raked off, but that will result in little improvement. We have sometimes found that turning the walk had a good effect, the rough being put under, and the fine brought on the top.

Annuals Round Fruit Trees (Scotland).—As the circles have been mulched with manure or saturated with liquid manure, any of the annuals, provided there is not too much shade, would probably succeed. Some most likely are:—Sweet Alyssum, white; Cape Marigold, Meteor, lemon striped silver; Candytuft, dwarf hybrid, rose; Candytuft, Empress, white; Cornflower, Victoria, blue; Eschscholtzia crocea; Leptosiphon aureus, yellow; Lupinus nanus, blue; Mignonette, dwarf erect; Nemophila insignis, blue; Poppy, dwarf French; double Jacobæa, and Venus' Looking-glass, blue.

Weevils (C. C. E.).—The specimens you have sent are very good examples of the clay coloured weevil, *Otiorhynchus picipes*. You wish to know their vices and virtues. We know their vices well enough, for they will eat almost any living vegetation, both under glass, in the form of Vine leaves and Fern fronds, and outdoors by feasting on the tender growths of Raspberries and Roses. In the larva state they eat the tender roots of various plants. Their virtues, perhaps, rest in affording food for something else that we do not know, and in quickening the activities of growers of plants and fruit in catching the depredators as you are doing. They are best seen after dark with the aid of a light when on their foraging expeditions.

Apple Twigs Eaten just Below the Pruning (Manse).—The Apple twigs have had the bark eaten off just below the pruning and on the side of the buds, but without injuring them. The gnawing, though only very slight, has been going on for some time, as some portions are brown, and others quite white, indicating recent attack. There are no insects, and the flies to which you allude do not gnaw but suck. Probably the animals are the stem-borer weevil, *Rhynchites Alliarie*, a very handsome creature, deep blue with a greenish tinge. It loves the Apple tree, and has probably found the sap "up" at the points of the shoots and got a start on the newly forming cellular tissue. Look very early in the morning or at night with a lantern, and you may possibly see the culprits. Or place a smear round the stem on a grease-proof band and the creature may transfix itself, though it does not often do so, but it certainly will not cross the sticky substance.

Eruptions on Under Side of Vine Leaves (A. W.).—The leaves have been microscopically examined, but no form of vegetable or animal parasite has been detected. The warts are considered to arise from a sudden depression of temperature or drying of the atmosphere by giving air in large amount at one time, and after the sun has raised the temperature considerably and increased the expansion, if not quantity, of air moisture. That such will give rise to warting, and even to scorching, every gardener well knows; but there are cases where "the eruptions on the under side of Vine leaves" cannot be so accounted for, and this appears your case, the Vines otherwise being vigorous and healthy, and the bunches quite free from the warting, or, as some term the leaf affection, rust. We have made careful observation of the phenomenon, and find that it proceeds from the stomata or breathing pores, where there is a thickening of tissue and abnormal growth of cells, which in some cases partake of the character of bark and dies, giving the leaves a semi-scorched appearance. We have noticed similar appearances on outdoor Vines and other broad-leaved plants, and for these no reason appears except chill, which may be, and probably is, the cause of the warting. But the fact remains, that where every possible care is taken in ventilating the warting occurs, and this rather points to excess of sap or development in too close and moist atmosphere. The pseudo-bulb is probably a species of *Dendrobium*.

Patent Crocks (Crocker).—We presume you refer to the wire crocks which were advertised in our columns some time back. They are manufactured by Mr. A. Porter, Stone House, Maidstone, from whom they may be procured.

XL All and Grapes (X. Y. Z.).—We are not able to say, from actual experience, whether Richards' XL All would hurt by fumigating the berries of Muscat of Alexandria Grapes, which are just stoning. Perhaps some Grape-growing reader who has tested the matter will oblige by giving the desired information?

Newly Planted Vines (Amateur).—When the Vines have taken to the soil, as will be indicated by their growing freely, ventilate early in the day, as the value of the growth is dependent more on its sturdiness and solidification than on its length and sappiness. Encourage laterals rather than mere elongation of the cane, but let that extend and retain all the foliage that can have exposure to light. That is desirable where the Vines are weakly; but if they are vigorous it is a better plan to pinch the laterals at the first joint, and to one leaf of subsequent growth, stopping the canes at 9 to 10 feet, and allow the uppermost to grow a few joints, and then keep all closely pinched. If the cane break into two growths cut away the worst.

Apple Tree Buds Destroyed by Birds (A. Z.).—The shoots are not, at least so far as we can discover, infested with insects, or are the buds in anywise affected with parasites. The birds take the buds solely as a source of food, and the delinquents are mostly bullfinches, especially in secluded positions. There are many palliatives, such as syringing the trees with hot limewash—that is, freshly burned lime slaked in the water, and formed into a consistency suitable for applying with a syringe, at once when the trees are quite dry. The limewash is not easily washed off by rain, and birds certainly do not relish the buds of trees so treated. The petroleum emulsion and the caustic soda and potash solution are useful, especially the latter, but it must be applied whilst the trees are quite dormant, and not after they are advanced in swelling their buds, which is the time when the birds mostly take them, especially of Apples and Pears. The gun is the best remedy. Trapping in early winter lessens their number, but in wooded districts is not sufficiently effective, but it is easy to use birdlime and a call bird to make a diversion in favour of the trees during the spring months. The petroleum emulsion may be used after the buds commence swelling, but duly diluted.

Tomato Plants with Drooping Disease (W. J. B.).—Yes, the stems are affected by the drooping disease fungus, *Fusarium lycopersici*, and certainly in the plants submitted it has gone over in the seed, as the roots are perfectly free from the parasite, only the radicle and root stem, with the stem above ground, being affected. No external application, therefore, would be of any use, unless such as to strike the disease plasma as soon as exposed by the germination of the seed. For this reason lime has a deterrent and often a fatal effect on the parasite, as it does not like this element, about 2½ per cent. of best chalk lime being mixed with the soil some time in advance of using, mixing with the lime some kainit—namely, 1 per cent. The kainit should be applied several weeks before the crop is planted, and the compost chopped down evenly and mixed thoroughly before use. This has been found effectual, so far as the soil is concerned, but there remains the passing over of the fungal plasma in the seed, and that can only be overcome by saving seed from perfectly healthy plants, never from a tainted stock. We have known bad cases greatly bettered by careful seed selection and the use of half the quantities of lime and kainit to the soil, the disease dying out or taking its departure.

Various Plants (J. C. S.).—*Euterpe edulis* is a stately Palm, growing to the height of 100 feet in Brazil, and requires a warm house for its satisfactory cultivation. The leaf you send is *Dasylicon acrotrichum*, an evergreen plant from Mexico, which succeeds in a not too cold greenhouse. Both *Gasterias* and *Haworthias* resemble small *Alces*, to which genus of Liliaceous plants they are closely allied. *Gasterias* have mostly red and *Haworthias* grey flowers; they are greenhouse plants, and require very little water during the winter. They are often seen with, and admired by, lovers of quaintly formed Cactaceous plants. By all means try them, and let them have abundance of sun in the summer and much more water than in the winter. Avoid very rich soil and needlessly large pots. *Kleinias* (also called *Cacalias*) are of excellent growth, the species varying greatly in character. *C. articulata* is commonly called the "Candle Plant," from its articulated candle-like stems. A plant called *Kleinia repens* (*Senecio succulentus*) is used in carpet bedding because of its blue tinted, fleshy growths. All the *Kleinias*, as well as the Liliaceous plants named, like crushed lime rubbish in the soil, and to be kept somewhat dry in the winter. They are more curious than beautiful greenhouse plants. *Pistacia Terebinthus* is a deciduous tree grown in Southern Europe, Northern Africa, and Asia for the Cyprus turpentine it yields. It attains a height of 20 feet, and has pinnate leaves. It will grow very well in the same kind of soil that you would use for *Fuchsias*, and would be as well out of doors as in a greenhouse during summer. We are obliged by your reference, and like to be helpful when we can to any of our readers. We do not regard searchers for knowledge as "troublesome," but rather as helpers in eliciting information that is often acceptable to others besides the querists.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as

to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*G. A., jun.*)—1, *Sempervivum chrysanthum*; 2, *Lychnis coronaria*. (*Daff.*)—Daffodils must be included within the category of florists' flowers, and, as such, can only be named by comparison. Your best course would be to send specimens to one of the several specialists, who no doubt would gladly assist you. (*G. C.*)—1, *Prunus (Cerasus) padus*, the Bird Cherry; 2, *Arabis alpina*; 3, *Aubrietia purpurea*; 4, *Iberis corneifolia*. (*L. W.*)—*Lycium europæum*.

BUTTER FROM THE ANTIPODES.

ENGLAND has many fair jewels in her crown—some jewels which have become hers at bitter cost, the cost of good men's lives; some that she has been obliged to take, to save them from themselves, from the despotic government of men worse than savages; and some that have come to her peaceably and quietly, the fruits of the adventures and hardihood of her sailors.

We are a restless people, never long content with our present position—in fact, our circumstances are such that we cannot be. The limits of our island home are too restricted—we have not scope here for our energies and desires. If we as elders settle down quietly at

home, there are always scores of younger sons who fairly burn and pant for a life of greater activity than can be found in the counting house or shop.

In days of old the simple country people believed the streets of London to be paved with gold. In these modern days gold is still the cry, whether of African origin, S. Australia, or the distant Klondike. But there are other motives that drive men, quite as potent as the gold fever—it is the lust of land; some stake in the country, some spot where to reign lord paramount. It is partly for the sake of possession, but also in great measure for the sake of the pleasant outdoor life, the fascination of rural sights and sounds, and perhaps in the far background the desire to demonstrate the possibility of making farming pay. We all have a sneaking fancy that we can excel our neighbour if we only really tried.

If in days of old Canaan could be looked upon as a land of flocks and herds, a truly pastoral country, surely to-day the same may be said of vast tracts of S. Australia. Shepherd kings, indeed! Well, here are shepherd kings in all truth, and alongside of the sheep may be seen the countless herds of well bred cattle, descended from the bluest of blue blood.

Imported bulls and dams have been used without a single thought being given to the great price paid for them in the old home country, or the great expense and risk of the long sea voyage. We know something of the expense, and we can guess at the risk. The colonials were wise in their generation, and knew that the best article was the cheapest in the long run. They have had their difficulties and their losses—many and heavy. They have met difficulties with perseverance, and losses with fortitude, and have ever been ready to seize and adopt new and improved methods if they could see in them at all ultimate profit. In a country like Australia, where the population is scanty, and the agricultural resources without limit, we cannot be surprised to learn that food products are both plentiful and cheap.

The question has been how to convey the superfluous food to those countries where the need was greatest, and where there was an open market. With beef and mutton the question was partly solved by the tinned trade, but with the bye products—milk and butter—there apparently seemed no means by which they could reach the far distant consumer.

However, now the difficulty appears to be at an end. We have received a paper which treats of the dairy factories of S. Australia, and shows how the work is growing and increasing. The increase is by giant strides. Once well made and carefully packed, butter and cheese will bear a great amount of travel without detriment, and the mother country will do well to be fed from her colonies, rather than from Danes or Dutchmen.

“Co-operation” is the watchword, and we find that “in Sydney the produce agents have formed themselves into a number of companies, each embracing a distinct sphere of action. Each company has a large butter factory established at some convenient point, generally at some river port, with creameries in suitable localities in the surrounding district.”

The farmer, instead of worrying himself and his family with dairy works, takes off his milk to the nearest creamery, sells it according to its intrinsic butter value, and has done with it. There is a monthly settlement, and he also may possibly be at the same time a participator in the company's profits. By doing his cows well he can increase the value of his milk, as it is paid for on the butter fat basis rather than on the quantity. As the factories are replete with the best and newest appliances, even to those used in pasteurising milk, every care is taken to make the butter as near perfection as possible. The products are carefully packed, and find their way to the home markets. This leaves the farmer free to turn his attention to other parts of his business; it does away with the employment of expensive labour (butter makers and dairymaids always require top figure in the matter of wage), and suitable offices.

We quote again, “On March 31st, 1898, there were in N.S. Wales 181 butter factories, 294 creameries, 18 cheese factories, 9 butter and cheese factories, 2 butter, cheese, and bacon factories, making in all

502 establishments, but during the last year the increase has been considerable. In 1897-8 the quantity of butter made was 29,409,966 lbs., of which 23,713,509 lbs. came from the factories, and 6,526,673 lbs. found its way chiefly to English markets. In 1886 the exports only reached 58,047 lbs., thus showing how quickly the trade is developing. We fancy it has a great future. The cows are there, the pastures are there, the go-ahead man is there too, and the capital wherewith to make a start.

Would that we could see something on the same lines in our rural neighbourhoods; but it is the old story repeated. Children may be taught new ways, their parents never. The young blood of the colonies is full of energy and life, it is not bound down by traditions of the past, but is ready to strike out new paths and try new methods.

WORK ON THE HOME FARM.

We are still having showery, not exactly to say wet, weather; the land, therefore, remains on the wet side, and current work is only performed with difficulty. A good May month should be a dry one, so we must hope that the weather will take up and give us a taste of summer.

Much rolling remains to be done, Bailey in particular is not growing as it should, the nights are too cold for it, and a crop which makes slow progress is always more liable to the attack of wireworm. Many fields show signs of wireworm now, and rolling must be done as soon as the weather will allow. A good heavy roll must be used, and the surface must be dry.

Farmers do not like to see a shed full of useless implements, but a spare roll is often brought into requisition when it is available, both in spring and autumn, and it is not an easy thing to borrow, for the neighbour who might be willing to lend is generally finding plenty of work for his own.

The sheep must now be removed from the mowing seeds if they are still on them, and here a good rolling will do much good. It will not only consolidate the Clover roots, but level the inequalities of the surface, and make a better track for the grass mower. Loose stones of any size must also be carted off. On limestone formation, stones of large size are often brought to the surface by the plough, and if not removed are a frequent cause of broken sections and fingers, if not of worse damages.

It will soon be time to drill a few early Swedes. Heavy soils, in which Swedes do not grow very rapidly, may be drilled any time after May 7th, if the tilth be satisfactory. A great point is to use good, new seed, not cheap rubbish or what has remained over from last year; and another point is to choose a fine warm day for the drilling. Sunshine must go in with the seed, and if there is none, then wait for it.

OUR LETTER BOX.

Malt Culms (N. B.).—We have no experience of these for the purpose you name, but we do not see why they should not be good for laying hens in the proportion you name, one part to three of meal. To your other question we can give no answer, though we should say it would be excellent for fattening chickens, being rich in nitrogen.

REMARKS.

23rd.—Frequently sunny in morning, with halo; cloudy afternoon; rain from 7 P.M. to midnight.
 24th.—Overcast early; faint sun about 11 A.M.; drizzle from noon, and steady rain from 2 P.M. to 8 P.M.
 25th.—Overcast with frequent rain early; frequent rain after 11 A.M.; heavy rain between 8 and 9 P.M.
 26th.—Rain in small hours; occasional bright sun in morning; overcast and dull from 2 P.M.
 27th.—Generally overcast, but some sun in morning; fine night.
 28th.—Overcast day, showery early.
 29th.—Alternate sunshine and showers.
 A dull week, with average temperature and rather more than average rainfall.
 —G. J. SYMONS.

BARR'S PURE GRASS SEEDS

For Lawns, Tennis Courts & Cricket Grounds.

The following mixtures are composed of PURE GRASS SEEDS only, which have been thoroughly cleaned and carefully mixed. They cannot fail to give the most satisfactory results.

We sell the seed by weight, which is the only correct method of estimating quantity needed for a given space.

BARR'S "THAMES EMBANKMENT" GRASS SEEDS for Parks.—A special mixture which has been found very successful in many public and private parks and squares around London and throughout the country. Per lb., 1/3; per 10lb., 10/6; per 20lb., 20/-.

BARR'S "STANDARD" GRASS SEEDS for Garden Lawns, Golf Links, Cricket Grounds, &c.—In this mixture there is a larger quantity of dwarf, fine-leaved Grasses than in Barr's "Thames Embankment." Per lb., 1/6; per 10lb., 12/6; per 20lb., 22/6.

BARR'S NEW MIXTURE OF DWARF GRASSES for producing an Extra Fine Smooth Lawn.—A special mixture of the finest-leaved and dwarfest-growing Grasses, producing an EXTRA FINE VELVETY TURF, and saving labour in not requiring frequent mowing. Per lb., 2/-; per 10lb., 18/-; per 20lb., 34/-.

Fuller particulars, with Hints on the Management of a Lawn, sent on application.

BARR'S NEW LAWN MANURE, "PHYTOBROMA," **WATSON'S LAWN SAND**, the best Weed Killer for use on Lawns. Full particulars on application.

BARR'S SEED GUIDE (free) contains a full Descriptive List of the best Vegetables and most beautiful Flowers, with many practical Hints on Culture, valuable to Gardeners, Amateurs, and Exhibitors.

DAHLIAS! DAHLIAS!! Ware's UNRIVALLED COLLECTION

We are now booking Orders for Delivery First Week in May.

Special attention is drawn to the two following beautiful NEW CACTUS VARIETIES for 1899.

Early Orders are solicited as the stock is limited.

E. O. GREENING.—Purple, shaded crimson, medium sized flowers, long and twisted petals; very free flowering; 2½ to 3 feet high. 5/- each.

SYLVIA.—Silvery-lilac shaded rose, splendid shade of colour, wonderfully free blooming, a splendid flower for cutting, lasting very long when cut; flower stem long and stiff; 4 feet in height. 5/- each.

NEW CACTUS DAHLIAS, Vars. of 1898.

Including such sorts as:—ARACHNE, CAPSTAN, FALKA, ISLAND QUEEN, LAVERSTOCK BEAUTY, RUBY, &c. 2/- each

CACTUS DAHLIAS, General Collection.

All the leading varieties. Our selection, 5/- doz.

SINGLE CACTUS DAHLIAS (New Type).

Our selection, 5/- per dozen.

DAHLIAS.—Singles, Pompons, Shows, and Fancies, in great variety. Our selection, 5/- per dozen.

BEGONIAS.

WARE'S GOLD MEDAL and 1st PRIZE STRAIN.

(If required started into growth, an intimation should be given to this effect).

Single—Mixed, 3/- per doz.; 20/- per 100.

„ To colour, 5/- doz.; 32/- per 100.

„ Extra choice, for Conservatory or Exhibition, 9/- and 12/- per doz.; 65/- and 75/- per 100.

„ Named sorts, splendid forms and colours, from 1/6 each.

Double—Mixed, 5/- per doz.; 35/- per 100.

„ To colour, 8/- and 10/- per doz.; 60/- and 80/- 100.

„ Gems for Exhibition, 18/- and 24/- per doz.

„ To name, THE FINEST EVER OFFERED, from 36/- per doz.

DAHLIA CATALOGUE, containing Illustrations of many new sorts, and list of varieties with full descriptions, post free upon application.

N.B.—All Orders amounting to 20/- and upwards when accompanied by cash, are sent Carriage and Packing free.

READY FOR THE QUEEN.

WHEN her Majesty was journeying from the Continent on Wednesday, 3rd inst., to her magnificent home, one of the many millions of the Queen's loyal subjects was running down to Windsor. He was there in time to see the 1st Life Guards come trooping in by road from London, but that was not the object of his visit. The country is inviting when the days are bright and the spring still young, and in searching for an excuse for a day out of town the happy thought arrived—Why not go and see the Royal Gardens when ready for the Queen?

The question was settled by a few quick electric flashes, and the writer was forthwith speeding onwards to the rendezvous. The best way to Windsor depends on the point of departure. If you are at Paddington you may reach the Royal borough in a little over half an hour; but if it take you an hour to get to Paddington it is a case of going a long way round for the shortest way there, that is if you happen to be near the South-Western line, in which case the longer route is, in the matter of time, the shorter, as it is for over most of the way the prettier, especially at this season of the year.

Reaching Putney from Waterloo we are on the fringe of a land of blossom. In the gardens on each side are pyramid Pears clothed in pearly beauty. Onwards through Barnes to Mortlake fleecy orchards come within the line of vision. Nearing Richmond we have Carter's trial grounds on the left, now neat and trim, but soon to be gay in many colours. Passing the orchards of Twickenham we come to the latest of the many Veitchian establishments—a new nursery of trees, on the right, at Feltham. This appears to be very much a land of fruit plantations, old and new, and we have not far to look for mountains of blossom till reaching Staines.

Here we swerve to the right and the scene changes, for we enter the flat, low meadows, that reach to the winding Thames. Willows are here the most familiar trees, with groups of Lombardy Poplars towering above them in spires of tender green. Passing Datchet, the wooded slopes of

No. 2641.—VOL. C., OLD SERIES.

Windsor come into view, with the great Castle rising above them. Nearer and nearer we are drawn towards it, but the train sweeps on as if leaving it behind, yet suddenly it takes a half-circular turn to the left, and we are brought as if within a stone's throw of the wonderful north terrace on its rocky bed high above the tops of the loftiest trees on the slope and in the foreground; but where all is so vast, distance is deceiving, and the visitor will find something of a walk or a climb before he stands on the level above, which a few moments before seemed so near.

But when the climb is over and the terrace reached, whether it be up the "hundred steps" (much nearer 200), or by the longer route round St. George's Chapel, and the atmosphere is clear, all will be forgotten, save the majestic building on the one hand and the glorious view on the other. It is as if taking a bird's eye glance of a vast pleasure ground extending over many square miles, the bright green fields between the trees resembling lawns, with the Thames winding its way in serpentine curves to the west till lost in the distant blue-tinted hills. The royal mistress of this regal home of British monarchs has during her wondrous career witnessed many scenes in Nature of entrancing beauty—scenes of grandeur in rugged cliffs, in heath-clad hills, in snow-capped mountains, and flowering slopes skirting southern lakes and sunny seas; but for quiet, pastoral, placid, restful beauty, of the true home type, it seems hard to conceive that even the Queen has viewed a fairer scene of its kind than this, when the light is of the best for revealing its peculiar charms.

ORNAMENTAL.

A few steps onward and nature in a large degree vanishes, and art is the dominating feature, for from the eastern terrace we are looking down on the fine semicircular flower garden, bounded by its castellated wall. This garden is essentially a work of art, with its fountain, statuary, neatly kept choice shrubs and Conifers, beds of Heather, and smooth lawn brightened with masses and lines of flowers. This is her Majesty's flower garden, overlooked every morning in the direction of the rising sun. The beauty of the enclosure is shared by the public, who have access to its great curving terrace walk on regular occasions, and Queen, princes, and people enjoy at the same time the flowers and the strains of one of the famous military bands. The flowers, now so bright and cheerful, are such as any cottager may grow—large masses of clear yellow, crimson, and particoloured Wallflowers; rich lines of the flower well named "Gold Dust," *Alyssum saxatile compactum*; long margins of rosy tinted double Daisies; sheets and lines of purple Aubrietias; creamy white masses of fine and floriferous *Polyanthuses*; bright blue Forget-me-nots, with groups of Daffodils here and there, and Pansies in the foreground. It is an enlivening floral scene, a beautiful setting to the well kept Hollies and other shrubs that are permanent features in the beds. And how easily all the flowers are raised, and none more easily than the dainty Daisies, for by sowing seeds now in the open, and treating the seedlings naturally, any number of fine plants may be raised to be clustered with flowers next spring. By its smooth lawns and paths, and closely clipped edgings—in a word, by its faultlessness in order, this garden was, as if assuming a smile of welcome, ready for the Queen.

From this eastern terrace, and curving gradually southwards, a drive leads through the Home Park on to the great walled supply gardens at Frogmore. In passing along it was pleasing to see how well every tree of some sixty *Cupressus atlantica glauca*, planted in June, 1897, was thriving. They are about 35 yards apart, and are destined to form a beautiful and lasting memorial of the unparalleled event they were intended to commemorate—the Diamond Jubilee of Britain's illustrious Queen. On asking Mr. Thomas what reason he had for feeling certain these trees would flourish in their position, he pointed to a noble specimen of a Cedar of Lebanon, and remarked, "That tree was planted by Mr. Ingram during the Queen's reign." The reply was conclusive. The matter had been well thought out, for where the Lebanon will thrive the Mount Atlas Cedar will flourish.

USEFUL.

The supply gardens are reached under a canopy of blossom—the branches of standard Pears being densely clothed from base to extremity; but we enter the houses first—or, at least, some of them, for to pass through all and along all the paths must surely mean a walk of a mile. What must arrest the attention of every visitor must be not only the thorough order and cleanliness prevailing, but to see how completely every structure is fulfilling its purpose. House after house of Vines, and every house giving its quota of Grapes, just such as are and will be wanted throughout the season. Duke of Buccleuch is bearing as heavily as any other, Madresfield Court colouring, Muscats and other late kinds advancing, and many little known and grown varieties flourishing in a young state. The foundation is laid for the most complete collection of Grapes in Britain, and it will be a wonder if varieties not yet seen have their birth at Frogmore. As with the Grapes, so with the Peaches and Nectarines, every tree in every house in the richest garb of health, and laden with fruit—not a failure to be seen. Cherries in abundance, ripe and ripening; Figs the same. Grand crops of Melons, many noble fruits of a new variety of the Beechwood type having been cut during the past three weeks, others ripening, and other ranges coming on. Strawberries Royal Sovereign and La Grosse Sucrée laden with handsome fruits, the crops from hundreds of pots exactly in to time, and others of the 10,000 grown following in order, to the later planted in pits for meeting the outdoor supply—a case of Strawberries under glass during the first six months of the year. As to Pines, it may be said in a sentence that nowhere are more to be seen or better than at Frogmore.

A word may be crowded in about vegetables, and perhaps a few about flowers, if the pen hold out and the patience of the reader should happen not to be exhausted. Peas, then, there are in abundance, sturdy plants heavily bearing in pots. Kidney Beans apparently by the bushel, and certainly Potatoes by the sack, ripe and ready for the great demand. Tomatoes in bountiful supply—the new plum-shaped Epicure, as great a favourite in its way as the well proved Frogmore Selected. A houseful of Cauliflowers in 6-inch pots, advancing to the heading stage, is not seen everywhere. Small tender heads of these are for the Royal table in lieu of the bigger Broccoli that go elsewhere. Asparagus forcing is over. What a demand there must be for this coveted vegetable, since half a mile in length of 5 feet wide beds have been planted this year for maintaining the supply; and so we might go on, but as a stop must be made somewhere in this section, it shall, as our affectionate brothers in the "States" would say, be made "right here."

But mention of the outdoor fruit must not be omitted. Peaches and Nectarines on walls are admirably managed, and their blossoms judiciously protected by movable blinds. It may be said that crops of these fruits rarely if ever fail. This year fruit is over-abounding, and not an insect to be seen on the trees. These are usually dressed with an insecticide before the blossoms open—an old and admirable practice. Apricots are less plentiful than Peaches. Plums and Cherries are setting in profusion. Pears are in full beauty, the branches densely packed with flowers—millions too many—and Apples will be much the same when the blossoms are expanded. The branches of bush Apples and free informal pyramid Pears are from 2 to 3 feet apart, each a cordon of spurs the entire length. No summer pinching is needed here, for the light and air act directly on the basal leaves of the summer growths, and hence the fruitful branches down to the main stem; in fact, where the branches are very thinly disposed, large trusses of flowers push directly from the central stem, and there is good promise that more than 90 per cent. of the trees in this great garden will be laden with fruit, but the haven of surety is not reached yet.

BEAUTIFUL.

As might be expected, the chief display of flowers was in the conservatory, and some of these were in preparation for the Castle. This means that whenever groups are wanted in the Royal apartments they have to be formed in the garden—every plant in its place to occupy the desired space, and thus the final arrangement is quickly done. The Lilac is one of her Majesty's favourite flowers, and a beautiful group of densely flowered plants of the familiar old colour,

with a few Arums interspersed, was being set up for subsequent transference, as indicated. Among the striking flowers in the conservatory were a number of Cinerarias of the "cruenta hybrids," the plants ranging from 18 inches to 3 or 4 feet high, with heads up to 2 feet in diameter of various self and parti-coloured miniature flowers—a home-saved and improved race, suggestive of small-flowered Michaelmas Daisies, but far richer and more varied in their several hues. Effective the plants unquestionably are, and the flowers for cutting are found most valuable. Many plants of the bright yellow *Celsia Arcturus* sparkled among Azaleas, Lilacs, and most other kinds in season; and the nearly 200 feet long sidestage presented a sight—well, certainly "fit for a queen." On the other side of this long building is a "dead" wall, against which nothing seemed to grow to give it life. It was a happy thought to plant in a border at the foot a row of slender Bamboos, and another row on the opposite side of the parallel path. They are luxuriating in the shady abode, and soon will be an elegant Bamboo border the whole length of the structure—a welcome change from the flowers on the other side.

Stove plants and Orchids, worthy as they are of admiration, must be passed without reference, save in the case of a consignment of the last named family. One house is occupied with Orchids sent to her Majesty by an Asiatic Prince from Burma. There are some 500 of them, and it is not easy to imagine the plants could have made a better start into growth in their native habitats. They are perfectly happy in their new home, and it will be interesting to watch and wait for developments.

The view from the long terrace walk in front of one of the great ranges of glass is, though over the kitchen gardens, at present chastely beautiful because of the blossom. This broad, smooth, newly-gravelled walk, with its side lawns, Conifers and balloons of Roses, is one of her Majesty's favourite drives to the conservatory. Not only is this fine promenade in the highest imaginable order, but every path and quarter and corner would bear close inspection. All seemed ready for the Queen; and all who had joined in work so well done, from the directing mind of Mr. Owen Thomas, his skilled foremen, and their bands of workers, would rejoice in the return of the Gracious Lady whom they are so proud to serve, for her Majesty's kindness and thoughtful consideration towards her servants of all grades is proverbial, and duty on their part is a pleasure and work—an exercise of love.

AMONG THE FLOWERS.

"The spring is here—the delicate footed May,
With its slight fingers full of leaves and flowers."

So sings the American poet Willis, and now that spring has in reality come, we can rejoice in its presence. Late as it has been, it is as welcome as in years now gone. The hedges and trees, so long bare, are clothing themselves with their charming leaves—never more beautiful than now, when, as it were, they are in their youth. Yes, the time wearied for is here, and we enjoy its manifold pleasures to the full. If we seek the woods we see the fresh green leaves above, and the bonnie Wood Anemones below. If we seek the fields they are spangled with Daisies, while the mossy banks are bright with Primroses.

But it is the garden's delights we seek to explore, great as are those of the outer world beyond. Many and sweet are these delights. The Daffodil has come late, and in consequence we are, as this is written, in full enjoyment of its gracious presence. On the heels of the trumpet varieties have followed those of the incomparabilis and poeticus sections, and these have caught up with their earlier sisters. Emperor and Empress are in the heyday of their beauty, and quite a number of the shorter cupped varieties are in their fullest charms. Grandis is not yet open, but preticus præcox grandiflorus has given us its clear white flowers and scarlet ringed cups. One cannot weary of looking at their flowers, or of admiring their impressive delicate loveliness.

In brilliant beauty have come "The courtier Tulip gay in clothes," as Fanshawe calls this other flower of the season. If, as Quarles says, "the fairest Tulip's not the sweetest flower," we can afford to overlook this fault because of the companions it brings whose fragrance is enough for our needs. If the Tulip has not perfume, and some few species have, the Wallflower can supply us with the sweet fragrance we want. In the garden of hardy flowers the Tulip with its gay colouring has its defects hidden and its beauties multiplied by its association with other herbaceous flowers. These give it the greenery it demands in addition to its own broad leaves.

As yet there are few open but the brilliant flowers of the early Dutch varieties. Exquisite are many of these, such as the delicately beautiful La Laitière, with its white flowers flushed with azure blue, the bright rich scarlet and yellow Keizerskroon, the fine yellow Canary Bird, the carmine-rose Proserpine, and the various coloured dwarf Duc Van Thol varieties. Later one may write of some of the species yet to bloom.

Owen Meredith tells us of the Anemones; he says:—

"The large-eyed Windflowers forlorn, too,
Blow among it unbeholden:
Some white, some crimson, others
Purple blackening to the heart.
From the deep Wheat sea which smothers
Their bright globes up, how they start!"

They are not "unbeholden" in the garden now, for those cups and globes of brilliant or of delicate colouring given by the Poppy Anemones cannot well be overlooked. They are hard pressed to hold their own when the early Tulips are afield, but they compel our admiration both by their colour and their form. The writer has been so fortunate as to have some tubers of the true St. Brigid strain, which, now that "St. Brigid" in her present garden cannot grow the Anemone so well, is being kept to its high standard by the Rev. F. C. Hayes of Raheny, Dublin. For many years this strain has been in the writer's garden, as it has been offered by the trade; but there are more plebeians than one could wish among the patricians of the race. "There is a black sheep in every flock," is a familiar saying; but there are not many inferior flowers among the Raheny St. Brigid Anemones. From almost white to purple and blue and crimson, with parti-coloured blooms, they are very beautiful indeed.

We admire *Anemone stellata* also, but its flowers look thin and poor beside those raised by the gentle lady who has so dainty a little garden in the Emerald Isle. If the Poppy Anemone has superior beauties to the starry Windflower, what can we say for the Wood Anemone? It is, as Shelley calls it, "fair and frail;" but though it is "frail" its fairness and delicate beauty make it as welcome in our gardens as the massive, brightly coloured flowers of the allied race. Bright are its varieties:—*A. Robinsoniana*, *A. cœrulea*, and *A. purpurea*, which look so well by the mossy stones of the rock garden.

"Streaked and banded" are the Fritillarias, but they are strangely liked by those who see them. Some few, of which *F. aurea* and *F. Bornmulleri* may be cited as examples, are bright in colouring, but by far the greater number are flowers not to be looked "at" but "into." We need to peep into their ball-like flowers to see their chequerings, their quiet colourings, and the glossy polish with which so many of them are so daintily finished. A small collection gives much pleasure now.

Before they wither away before the summer sun, one may well say a word or two in praise of the Grape Hyacinths. How few in many districts know these, it seems almost sad to think. People will spend their money on the flowers of autumn, but how many do not heed the flowers of spring! One would not unduly disparage the gems which give us our autumn's joys, but it is brought home to one again and again that the wealth of floral beauty spring can give our gardens is unrealised by the many. If they want little cones of blue and white, clustered heads of sweet little flowers, hardy as the Daisy or the Dandelion, let them buy a few *Muscari* in autumn, and when spring comes round they will not regret their purchases. For a bit of bright blue there is *M. botryoides*, for another there is *M. conicum*, and for a lighter colour and a smaller flower there is *M. Szovitsianum*. There are many more, but none more pleasing perhaps than those. But time speeds and space is limited, so "hasten" must be the motto call to move the pen.

Sheets of Aubrietias—red and pink, and blue and lilac, and mauve—keep company with the white Arabis. White and yellow, and pink and red, and blue Primroses and Polyanthus brighten up border and rock garden and roughish nooks. *Primula* species, sadly thinned by the past unfavourable winter, are in bloom. *Primula Sieboldi* in variety is just opening. In the rock garden it has grown into clumps, which want thinning out. Violas begin to give us many flowers, though nearly all their fragrant sister Violets are past and gone. Great sheets of Candytufts will more than rival the Arabis in whiteness, and will give us their snowy blooms when the other has lost its beauty for the year. There is *Erica mediterranea*, with its bead-like flowers; and Mr. D. S. Melville, of Poltallock Gardens, kindly sent some beautiful sprays of *E. australis*, to show its worth.

Crown Imperials and the simple Honesty stand tall among so many dwarfer flowers, and rock garden shrubs, such as the lovely *Cytisus præcox*, become gay and bright. Near by *Kerria japonica* fl.-pl. is crowded with its yellow Chrysanthemum-like double blooms, and Forsythias have not yet quite passed away.

Adonis vernalis opens its flat golden flowers on its shaggy, rough looking foliage, which is, however, as soft as it looks spiny. *Dentarias* (now merged into the *Cardamines* botanically) are pleasing, and sheets of Mossy Saxifrages grow white or purple, as the case may be.

Truly, as the poet says, "Fair-handed spring unbosoms every grace." To the youth the future is always distant and hoped for, but to many of us the sweet time of spring, with its flowers, will pass too quickly away. Summer and autumn have their garden graces, but none is fairer, none more fascinating, than the gentle blossoms of the sweet time of early May.—S. ARNOTT.

FRUIT PROSPECTS ROUND EVESHAM.

PERHAPS you may be able to cull some information from the enclosed report from the "Evesham Journal" of a meeting of some of the old Evesham Fruit Pests Committee at Toddington on Thursday last. The trials of the spraying machines were most interesting, but so far as insect pests were concerned they were conspicuous by their absence. My opinion is that the intense frosts in March settled the bulk of them, and the later frosts the bulk of the Plum crops.—J. HAM, *Astwood Bank*.

"Looking to the future there is a great deal of misapprehension as to the Plums. In the low-lying grounds the frost has done much damage, and taking the Evesham gardens all through, two men who are qualified judges place this year's crop at twenty-five, taking 100 as the average. If this should prove to be correct it will be a poor outlook for those gardeners who place most of their reliance on the Plums, but we hope it will not be found to be the case, and we are the more strengthened in this hope by the fact that other growers place the probable yield much higher—more like fifty. As is generally the case, the frost has behaved in a capricious manner, doing much injury in some grounds, and leaving others untouched.

"The early Plums, Prolifics and Czars, seem to have suffered most, and some of those that flower early, such as the Monarch, which does not come into the market till later, have also been touched. In some of the gardens there is scarcely a Plum left that is good for anything, and in some cases the cold weather has so checked the sap that the leaves on some of the boughs are withering just as if hot water had been thrown over them, and the boughs, when you break them off, are brown just where the sap runs. This is particularly the case with some Victorias we saw at Pershore, and the same thing has occurred in some of the Toddington plantations. Egg Plums were a good bloom, and generally they seem to be setting well, but in some of the plantations they are a good deal cut up, and so are the Victorias, though in favourable situations the prospect is fair. The Damascenes seem to have suffered as severely as any. In some places there are scarcely any left, and some of the growers will be in the position of a well-known Evesham man, who has some ground at Hampton, and who some years ago carefully placed a single Plum in the middle of a pot hamper, and exhibited it to admiring crowds as his crop for the season. Unfortunately, though the season is bad enough so far, the worst is not yet apparent. When the Plums are stoning, and about the size of Hazel nuts, we shall see a good many of them fall off, and this will still further thin an already thin crop. However, we must hope for the best. A very heavy crop does not always pay the best, and perhaps the small yield of the present year may not be such an unmixed evil as some people would have us believe.

"As to bush fruit, Gooseberries are practically the only ones that anything need be said about. Here again our pessimistic friends place them at a quarter of an average crop, but other growers say they were not hurt much, and will be a fairly good crop. This divergence of opinion may be attributed to the difference in the situation of the gardens, for, as is always the case, some of the gardens have escaped comparatively lightly, while others have suffered severely, and possibly those who take the worst view of things have seen most of the bad gardens.

"With regard to insect pests, they are not so apparent as they have been in many past years. Thanks to the investigations of the Fruit Pests Committee, the gardeners now know how to deal with them better than they did some eight or ten years ago, and the difference in the gardens is most marked. The general adoption of the practice of grease banding for the winter moth has resulted in a great diminution of the caterpillars on the Plum trees, and the aphides and other pests are not doing the damage they did in previous years. Red spiders are still a source of trouble, but they are got rid of without very much trouble by spraying with quassia and softsoap, soda, and other preparations. They are mostly seen in the old plantations. The Gooseberry caterpillar, too, has not been seen lately. Whitewashing the bushes in the winter to keep the bark clean and healthy is found an excellent remedy. In one of the Wyre plantations the thrips are found this season in considerable numbers.

"Speaking of Wyre reminds us of Mr. George Eccles' Apple plantations. Mr. Eccles is a great believer in Apples, and he says there is a great future before Apples as a paying crop. The Yankee growers have, he thinks, had their day, or pretty nearly so, for the English growers are beginning to see that there is money in the Apple tree, and when we state that Mr. Eccles made last year from 8s. to 10s. a pot for his Apples we can quite believe that there is in them a line that the growers in this neighbourhood would do well to take advantage of. Compared with other fruits it costs very little to pick them—about 1½d. per pot, and there is always a good demand for decent Apples. Last year Mr. Eccles put on the market some large Apples that made 1s. 6d. a peck, which is about 1½d. or 2d. each. He only grows choice sorts, on Paradise stocks, and treats them

well. Shoddy, soot, and certain other artificial manures, with a dressing of lime, are found very useful.

"Some of his Newton Wonders last year made 2s. a pot more than the Blenheims, and he has a row of Peter the Great, an early table Apple, which last year were heavily laden. His Apple plantation, which consists of some 1500 trees, looks very well this season. He grows them between the standard Plum trees, and finds they do very well on rather heavy land. He does not care very much about Lord Suffield. For early varieties he recommends Potts' Seedling, Ecklinville Seedling, and Lord Grosvenor.

"Mr. Eccles is a Tomato grower also. This year he is putting in 9000 or 10,000 plants, and he prefers the Early Ruby to the Early Evesham. Last year he grew the French variety, known as the Chemin. This is really an indoor variety, but last year he found it answered well out of doors with the others, and improved the sample. He does not sell his Tomatoes on commission, but sends them direct to the shops, nicely packed in 12 lb. baskets, and all the defective ones carefully picked out, so that in a ton there is hardly a pound of bad ones.

SPRAYING AT TODDINGTON.

"At the Toddington gardens on Thursday afternoon we witnessed an exhibition of spraying machines. We were first shown a washer designed by Mr. Wise and built by Messrs. Weeks & Co. of Maidstone. This machine is drawn by a couple of horses, and consists of a tank for the insecticide, and so geared to the wheels as to throw a strong spray from four nozzles held by as many men. There is an interchangeable action which enables the machine to be worked over Strawberries or between Raspberries, for spraying Plum trees. This should prove very useful for grass orchards, or plantations where there is no bush fruit between the Plum trees, but in the Evesham gardens it would not be much use, as it could not be got between the rows of Plum trees with any facility, and in some cases not at all.

"The principal event was an exhibition with a new steam sprayer made by Messrs. Merryweather & Sons, the well-known fire engine people of Greenwich Road, London. This is a far and away the most efficient washer we have seen. It consists of a portable steam pumping engine of about six horse power in connection with a system of iron piping, which is laid along the top of the plantation as a main. The piping is in convenient lengths, each length being fitted with a piece of flexible anti-caustic hose at each end, and quick-hitching gun-metal couplings. A number of tee pieces are provided, each with flexible hose and couplings, and in work these tee pieces are connected between two lengths of pipes. Each tee piece has a cock attached, and by means of breechings, lines of hose pipe can be led away to supply jets or sprays. This system of pipes can be laid down between the rows by a few men in a very short time, and enables the washing to be done rapidly and thoroughly, there being no small hand pumps to be filled with insecticide. The insecticide is mixed in a tank placed on the ground alongside the engine, and is pumped continuously into the portable pipe system. Each man has a long jet pipe with a spray nozzle, and a cock is fitted to each pipe, so that any of the jets can be shut off independently.

"The engine and boiler is very light, and the pump is of rustless gun-metal, with copper air vessels and gun-metal pipe connections. It is fitted with a patent injector for keeping the boiler supplied with water, as well as with a lever hand pump to fill boiler when starting work. An important feature is that one or the whole of the sprays may be shut off at once without stopping the engine, a special by-pass valve being fitted from the delivery to the suction pipe, and thus the man in charge of the engine can keep one or the whole of the jets supplied at an even pressure. By means of this apparatus a large number of trees can be sprayed in a very short time, and sprayed very effectually too, for each man can spend as long as is necessary at each tree or bush; he has no weight to carry about as in the knapsack pumps, and there is no time lost in filling the tanks. For standard trees the nozzle is held on the end of a cane, and the tops and hearts of the trees can be dealt with. By an arrangement of the valve the strength of the solution can be adjusted to a nicety.

"We doubt whether it would pay a man with a small plantation to buy one of these sprayers, but for large growers it certainly seems the most efficient thing in this line that has yet been put on the market. The engine can also be used for pumping water and watering plantations in times of drought, for driving light machinery, such as chaffcutters, and as a fire engine in case the owner should be so unfortunate as to have a fire. The engine is very small for the horse-power it develops; it is fitted with a tubular boiler so that steam can be got up in a very few minutes, and it seems to be fitted in every way for the work it has to do. Mr. Maryon, Messrs. Merryweather's representative, was present, and very courteously explained all the details to those present. The apparatus has not been on the market long, but where it has been tried it has proved most successful."

EPIDENDRUM ELEGANTULUM LUTEUM.

IN the spring of 1896 Messrs. J. Veitch & Sons, Ltd., staged at one of the meetings of the Royal Horticultural Society *Epidendrum elegantulum*, for which they received a first-class certificate. This was stated to be a hybrid from *E. Endresio-Wallisi* and *E. Wallisi*, and it was greatly admired. Following this up the same firm sent to the Drill Hall on Tuesday, May 2nd, *E. elegantulum luteum*, and received for it an award of merit. The flower as shown in the engraving (fig. 85) is of chaste beauty, and attracted the attention of all visitors. The colour of the sepals and petals is clear yellow, and that of the beautifully fringed lip pure white.

MASDEVALLIA SHUTTRYANA.

THERE is probably not a more handsome *Masdevallia* in cultivation than this beautiful hybrid, and an especially fine form of it was shown recently at the Drill Hall from the celebrated Burford Lodge collection. It was a plant carrying about a dozen flowers, and rarely has a more interesting exhibit in this section been staged. The Orchid Committee gave it a first-class certificate, which everyone agreed was well deserved, for the plant was a magnificent one, to say nothing of the fine variety.

It was labelled Chamberlain's variety, and was raised in the Highbury collection, the parentage being *M. Shuttleworthi* and *M. Harryana*, both handsome species. The flowers are intermediate in shape, and very distinct, the long curving tails being bright yellow at the tips, shading off to a deep magenta tint, this being continued over the broad part of the sepals, the bases of which are spotted with brownish purple. The dorsal sepal is yellow, with markings of purple, the lip white. The splendid habit of these hybrid forms is very noticeable, this one being a really fine grower, though one at least of its parents is not noted for robustness. It may be mentioned that the original type of *M. Shuttryana* was raised at Burford in 1892.

DENDROCHILUM GLUMACEUM.

This, when well grown into a fine specimen and well flowered, is one of the most beautiful Orchids in cultivation, the long arching racemes of yellowish flowers hanging about the plant like "gold filagree work chains." These occur upon the forming growths, and occasionally the plants are checked by being kept in a cool dry house to conserve the flowers. There are few plants that are exposed to moister conditions (in their habitat) than these, for a distinguished French traveller who has seen them growing *in situ* remarks that they grow attached to the tree trunks from 6 feet to 12 feet high, the forests in which they are found being so damp that for nine months in the year leeches live there as if they were terrestrial.

This being so it is obvious that a drying at the time when the growths are barely formed must be a serious check, and anything of this kind is bound to bring insects in its train to the further detriment of the plant. Their epiphytal habit points to the fact of little being needed in the way of compost, and when grown in pans for suspending, these ought to be almost filled with drainage, just the top inch or so being made up of clean sphagnum moss, peat, and charcoal. While growing freely give ample root moisture, but when the plants are at rest only sufficient to keep the pseudo-bulbs plump is needed.—H. R. R.

CATTLEYA CITRINA.

THROUGHOUT the sixteen years during which I have grown this plant, it has always been a kindly grower. Its "personal attractions" are so great, and its habit of growth so curious, that I had said if ever I grew an Orchid it should be *Cattleya citrina*. So it came to me from the first, in spite of assurances that it would be "bad to do." Why it has done well I hardly know, beyond that I fell in love with it at first sight, and watched its ways.

I saw by the marked preference its roots have for getting away from coverings of any kind that an almost naked raft suffices for it, and that any kind of material in decay is an abomination. The plant must be attached in its own peculiar position, which, to the eye, looks like an upside down one. But as the rich heavy flower is pendent, and no water must lodge between the leaves of young growths, the natural position of head downwards is at once the easiest and the best. The young foliage is thus placed thatchwise, protecting its own heart, and "turning water" as perfectly as a *Nasturtium* leaf surface does.

However, in giving water by dipping the plant, it is possible that some may be held back, where young leaves meet; and if only a "bead" or two be retained among them, then one or more ruinous

black spots are likely to appear, which will eventually destroy the whole leaf, unless the affected parts are cleanly and entirely cut out. Syringing might do, if the water could fall like a tropical rain; but the squirting charge is apt to scatter and lodge a few water-pellets in a young heart. Whichever way is adopted, the plant should be well shaken to dislodge any water from between growing leaves, which will often, with misplaced confidence, conceal it.

On the flower stems of *Cattleya citrina*, twin blossoms are generally proposed, but not very often carried out. If a pair get a fair start in life together—i.e., leave their bract simultaneously, each may live to be a flower (if the plant has health and strength); but a bud, with a trifling lead, will increase it so fast that the other one soon gives up in despair. The plant rests awhile after the flowering period, which, with a fair number of plants, is with me a very extended one, though they all grow together in one house the year round.

I never grew *Cattleya citrina* in a cooler than a full *Cattleya* temperature. It is a decided grower through the winter with me

FIG. 85.—EPIDENDRUM ELEGANTULUM LUTEUM.

and I did not think that, at periods of active growth, it would be best pleased with a winter residence in a low degree of warmth.

The plants are kept as close to the glass as possible, and as long as any roots are active I do not entirely withhold moisture. *C. citrina* is very moderate in its requirements in this respect at its quiet times, but I have never allowed the pseudo-bulbs to shrivel. Neither can I say from experience that it will not flourish in a cool house, and it is only in response to a kind invitation from the Journal for correspondents to say what they have done with *Cattleya citrina*, that I make bold to state my way with it.—F. D. HORNER.

BROCCOLI.

IN a season when green vegetables are scarce, the value of good quarters of Broccoli can hardly be over-estimated. Snow's Winter White, for instance, is one of the most useful, filling the breach after the autumn Cauliflowers are past. It is hardy and good, with a medium sized nice white curd on stems about 18 inches high. Only too often the Snows sold, especially by local seedsmen, grow nearer a yard in height, and either they do not show a curd at all, or we get one about 2 inches across late in the season, when better varieties are in. There are plenty of good midseason sorts that will keep up a succession from quite early in the year until the end of April. Two capital ones are Vanguard and Safeguard, the former being earlier than the latter, but not so hardy. Eclipse may be grown where medium size heads are required, and though after the end of April Broccoli is hardly needed, if there is room for growing hand-light and frame Cauliflowers, there are many places where conveniences do not exist for the purpose.

I grow a large number of late Broccoli, and two of the best I have tried are Methven's June and Late Queen. There are few more useful

vegetables than the latter where a large demand has to be met with limited accommodation, for it is dwarf and compact in growth, very hardy, and never turns in until quite the middle of May. Methven's is even later, but not so large or distinct, and therefore not so much to be depended upon.

With regard to transplanting Broccoli much misconception exists. By all means prick out the plants if room can be found for them, but when they have been pricked out they must not be drawn again and planted with a pin or dibber. This does away with many of the best roots, while those that remain are crowded and cramped into a hole not large enough for them. Drills should be drawn, and after well soaking the plants they should be carefully lifted and planted out with trowels. I never dig the ground for Broccoli; it follows whatever crop is on the ground, with no more preparation than a light hoeing and raking. When Strawberries are grown on the three-years principle, no better place than the old beds can be found, simply hoeing off the Strawberries and planting direct.—H. R. RICHARDS.

BLACKBERRY CULTIVATION.

I WAS pleased to see Mr. Luckhurst's note on Blackberry cultivation in your issue of last week (page 355). I fully agree with him that this is a much-neglected fruit. I am also at one with him in the conclusion that one great reason of its having failed to establish itself in the favour of the public is that most people look upon it as a common fruit unworthy of a good situation and fair cultivation, in fact it is usually relegated to the coverings of rough rockeries, banks, or any out of the way corner; but I think a still stronger reason is that many people class the Parsley-leaved Blackberry, *R. laciniatus*, amongst the American Blackberries, so many of which have been tried and found wanting, and thus condemn all alike, without giving our English friend a trial.

It is, of course, known to many that the Parsley-leaved is a British variety, having been found many years ago as a chance seedling in a bed of pot plants at Handsworth Nurseries; but this knowledge cannot be too widely diffused, for, to tell the truth, most of us are a little sick of American berries of all kinds, and to call our friend by this title is with many to condemn him at once.

I do not know why our climate does not suit the American Blackberries, but certainly no one on this side the Atlantic has succeeded in growing fruit to equal the photographic reproductions which induced us to buy these much-belauded berries. I must confess that I have sometimes wondered whether the photographic art over there was in advance of ours. We have now tried a great number of these berries, and one has to confess, when asked by intending planters what are their merits, that they are small from a practical point of view, however interesting they might prove at a hybrid conference.

There is the Japanese Golden Mayberry, which one bought on Mr. Burbank's recommendation, coupled with a most taking illustration of the fruit. I am the more sore about this, because we imported a good many and sold them freely, and if our customers' experience with them is no better than our own, we are doomed to a considerable share of abuse, either outspoken or otherwise. The first year the plants were imported late, and were very small, but last year we expected great things, when lo! the spring frost cut all the young growth, and no fruit appeared; and now, having grown some fine plants, the March frosts this year have killed them back to the ground; this, like the Japanese Plums, is evidently not for us.

Then, again, take the Strawberry-Raspberry; it is certainly a very pretty border plant, and whether in bloom or fruit interesting and attractive. But as a fruit—well, the blackbirds disregard it; and I need say no more. These same judges are not keen about tackling the Blackcap, and I agree with them there. As to the Loganberry, whilst it may prove useful for jam-making—I think it will, but it needs a good deal of space, and I fear many people will grudge the land it requires. Last year we had a hedge of the Parsley-leaved Blackberry growing alongside these other fruits, and one could fill a small basket with the berries without moving one's feet, added to which the flavour was such that all visitors, whether feathered or otherwise, passed by all others in their favour.—A. H. PEARSON, *Chilwell, Notts.*

[We gave prominence to Mr. Luckhurst's notes because of the splendid crops of fruit we have seen of the Bramble under notice, chiefly in gardens around Sheffield, and because Mr. Luckhurst pointed out the cause of many failures, also of the method to pursue to establish robust and fruitful plants of the English Parsley-leaved variety. The late Mr. Woodcock used to grow bushels of splendid fruit for Mrs. Firth near Sheffield, the plants being trained over tall trellises and arches. They produced ten times more fruit than could be obtained from Raspberries, however well grown, while the value of the Blackberries was enhanced by coming into use when all other berry fruits were over. They made fruiting canes from 10 to 15 feet long, which were laden with huge clusters, amounting to bushels of fruit. The Parsley-

leaved ought to have been named the Handsworth Giant Blackberry, as it is distinct from and far superior to *Rubus laciniatus*, which is, we think, of American origin, but of this we are not certain. We have known many failures in establishing fruitful plantations simply because the canes were not cut down for at least two years, or until robust growths issued from the ground. When they do and the soil is rich and deep, the crops are prodigious, but weakly growths from mismanaged plants in poor dry soil are very disappointing.]

HYDRANGEAS.

WHEN we remember that thousands of young plants of *H. hortensis* annually find their way from the premises of the trade growers to the various markets, and thence to the many homes of individual buyers, one is tempted to wonder what the final resting place of such numbers must be. When dwarf Hydrangeas are produced, as our best market men can grow them, the plants are objected to by some persons because the great whorls of inflorescence give the idea of top-heaviness, but notwithstanding this objection I think that such plants will long remain public favourites, as they are distinct from all others, and remain effective over a considerable period.

Hydrangeas are easily propagated from cuttings by selecting stout young shoots in the early part of July, trimming off the lower leaves, and making a smooth clean cut, so that the stem may rest on a firm base when inserted in the soil. We have found it the best plan to insert the cuttings singly in 2½ or 3-inch pots, rather than a greater number in those of larger size. If placed in a close frame in a warm house they emit roots quickly, though they are not slow in doing so in an ordinary Cucumber frame if shaded from the sun. Some growers transfer the small plants to slightly larger pots, and give another remove in early spring if found necessary, but others have found the method of wintering the young plants in small pots, and shifting them into 5 or 6-inch sizes in February, perfectly satisfactory. Thousands are grown in the manner indicated, and a saving of time and space effected.

Some growers insert sturdy cuttings taken from old plants in the spring, and if the growths thus selected have bold buds in their points the plants flower the same season, but the greater number, and, as a rule, better plants are obtained by late summer propagation. After flowering, and the removal of the old decayed trusses, the plants after hardening are stood in the open air during the summer months. If large specimens be required, they can be had by growing them in suitably sized pots in a substantial compost of loam with a small proportion of decayed manure. If the loam is very heavy, an admixture of leaf soil and sand may be advantageous.

Old plants of *H. hortensis* stand the winters in the southern parts of the kingdom, if during very severe weather a covering of litter or bracken be placed over them and the pots are plunged in ashes. In the growing season water is required in abundance, with liquid manure occasionally. The variety Thomas Hogg, which has been deservedly recommended for forcing, should be grown. The flowers are white, freely produced, and may be had early in the season. I have found this form to succeed very well by the method of planting out in summer and lifting again in autumn, in the same manner as is often practised with Callas. The treatment otherwise may be identical with that of *H. hortensis*.

H. paniculata and its companion, *p. grandiflora*, are usually regarded as outside border plants, but with cool treatment in pots they are extremely useful for house and conservatory decoration. *H. p. grandiflora* associated with *Tritomas* in the foreground of shrubberies combine in forming a splendid floral picture, the long pendulous trusses of the Hydrangeas contrasting most happily with the glowing spires of the "Red-hot Pokers," and both are effectively displayed by the background of shrubs. In localities where the soil and climate are favourable, *H. hortensis* assumes the form of large permanent bushes out of doors, and when covered with trusses of varied tints forms the grandest of summer flowering shrubs, which materially add to the beauty of gardens and pleasure grounds.

Much has been written from time to time as to the best method of producing the blue tint of colour in Hydrangeas. In some soils the flowers are blue, more or less intense, the soil then contains iron. Where it is not present a solution obtained by steeping iron filings in water and given to the plants, has in some instances assured the desired result, but there have been disappointments. The Hydrangea does not appear to have many insect foes, green fly on the young growths appearing to be the most troublesome, and this is often caused by too much heat and too close an atmosphere. As frequent and copious supplies of water are necessary when the pots are full of roots, it is wise to stand them in saucers, as otherwise it is obvious that much of the fertility of the soil would be washed away. Let the water that collects in the saucers be imbibed by the roots; then, and not till then, give more to the soil to pass through to be collected again, and Hydrangeas will flourish.—J. SHALFORD.

APPLES AND AMERICAN BLIGHT—FRUIT TREES ON "OWN ROOTS."

HEREWITH I send extracts from a letter received this week from Mr. Palmer, Auckland, New Zealand. Mr. Palmer and myself are quite strangers, except that we both belong to "The Journal" brotherhood, and I think it very kind of him to write me such an interesting letter. I scarcely need say I have written thanking him and accepting his offer of cuttings, and shall get them worked. If we can only get one good all-round variety to resist the "blight," and at the same time be a good stock to work others on, it will be the very "finest Apple on earth" (vide Merryweather). Some parts of Mr. Palmer's letter are omitted, as they are substantially the same as his letter in the Journal of March 30th last.—JOHN ERTLE, *Weston-super-Mare*.

EXTRACTS FROM MR. PALMER'S LETTER.

I was much interested in reading your letter in the *Journal of Horticulture*, December 22nd, 1898, especially that portion on American blight. I have been a resident in the North Island of New Zealand for upwards of forty years, and from my first landing have taken great interest in fruit culture and horticulture generally. When first I came to this country very few of the Apples grown would resist the American blight for any length of time, both root and branch being covered with it. I turned my attention to finding a remedy, but could not succeed. The great difficulty was with the roots. Noticing the Irish Peach Apple was not attacked, I thought if I could get it on its own roots, and still find it clean, it would answer for a stock, and the greatest difficulty overcome by having the roots clean, using something on the branches that would keep the aphids in check for the time being. I found the Irish Peach, as far as the roots were concerned, to answer, but it was not a very suitable stock, especially for strong growing varieties.

About this time a gentleman, Mr. Lippiatt, came out from the Old Country and brought with him a number of Apple and other fruit trees. After they had been planted some time the Apples were attacked with the blight, root and branch. But amongst them one variety remained perfectly clean as far as the branches were concerned, but the stem below the graft and the roots were attacked. The variety was the Northern Spy, and I believe the first of that variety brought to New Zealand.

I procured some grafts from Mr. Lippiatt and grafted them on pieces of roots of the Irish Peach. Most of the grafts grew strongly, and on taking them up at the following planting time we found that all the grafts had thrown out a mass of fibrous roots from themselves, which at once convinced me the Spy would be a suitable stock for other varieties of Apples. This happened about thirty years since. About that time, Mr. Laing, I think, of Ballarat, Australia, discovered that the Winter Majetin Apple was also a resistant variety, and propagated it largely. I obtained some plants from him, but owing to its strong, straggling, fibreless roots, I have discarded it as a stock. Shortly afterwards, someone in Australia discovered the Spy, and found it the better stock, and I believe to-day no other is generally used in that country.

I know how difficult it is to introduce any change into old countries, nor have I any interest in recommending the Spy as a stock, further than trying to benefit others. Some years ago I was accused by one of the correspondents of the Journal with sinister motives in so doing. The writer said that my motive in recommending it was that I was aware of its unsuitability for the English climate, and if its use was adopted it would leave an opening for the Australian grown fruit. Seeing that our seasons are opposite to your own, and at the time our fruit reaches you your markets are generally deficient, I cannot see where his remarks apply.

I also see in one of the Journals a controversy about fruit trees on their own roots. Few people have tried more experiments in that way than I have, and I feel sure it is a subject that wants more ventilating. By grafting or budding we force a plant to grow on a root that may not be congenial to it, whereas on its own roots it adapts itself to circumstances, producing roots according to its nature. I am not making this statement without foundation, as in numerous instances I have found it to be correct.

The two best Pear orchards of which I know, the trees are growing on their own roots, having originally been worked on Quince roots and planted rather deeply, below the junction. Last winter during a gale of wind one of the largest trees blew over. There was no sign of tap or deep penetrating roots, yet the land was a rich alluvial deposit. The original Quince roots were still alive, but did not appear to have made much progress. Last year from this Pear orchard, some three acres in extent, about £300 worth of fruit was sold. I know of numerous fruit trees on their own roots doing and bearing better than the same varieties alongside grafted on foreign roots. I am not setting it down as a hard and fast rule.

There is another thing I would like to mention with respect to Apples and the woolly aphid, and that is the raising and selecting of seedling varieties that are not subject to attack. I think I could

select at least twenty seedling varieties that are perfectly free from attack, most of them of superior quality. If you would like a few cuttings I should be glad to send you some. Leaving here in the month of June they reach England in the budding season, when, by taking off a very thin slice of bark with the bud and inserting it as it is in a free growing stock, very few will fail to grow freely another season. A short time since I received clean cuttings from Messrs. Bunyard & Co. I inserted buds in the way mentioned, and many of them have shot, nor do I see a failure. Should you feel interested in what I have written, I shall be much pleased; also if you will take the trouble, shall be glad to hear from you in the meantime.—W. J. PALMER, *Government Pomologist, North Island, New Zealand*.

[We are very much obliged to Mr. Ertle for his letter and enclosure. Mr. Palmer's interesting letter was written some time before he penned his communication on "Northern Spy Apple for Stocks," which appeared on page 258, March 30th of the present year. We are gratified to know that many friendships have been made through the "brotherhood of the Journal," and not a few of many years' duration and mutual advantage.

Mr. Palmer is evidently a close observer, and quick in turning suggestive hints to account. Finding no American blight on the branches of the "first tree of Northern Spy Apple brought into New Zealand" from England, but "the stem below the graft, also the roots attacked"—i.e., the stock supporting the clean Spy, he commenced experiments, with the eventual result of the Northern Spy becoming the generally used stock in New Zealand, because from some scientifically unexplained, yet very practical, reason the varieties established on it were free from attack by the ruinous woolly aphid. We may perhaps hear more from Mr. Palmer on this subject.

On another point in Mr. Palmer's present letter we should like to dwell for a moment. Though we do not remember a writer in our columns stating that "Mr. Palmer was aware of the unsuitableness of the American Spy" (as a stock presumably) "for the English climate, and if its use was adopted it would leave an opening for Australian grown fruit" in English markets, we have no hesitation in saying that such a sentence, having regard to existing facts, now represents nothing more or less than a case of "antiquated diplomacy."

We do not know an English fruit grower worthy of the name who deplors the importation of Australian Apples when he has no fruit of his own; but we do know of home growers who purchase the Australian produce readily enough, and would be rather sorry than otherwise if it were not obtainable. As a matter of fact, the most skilled of British fruit growers are wisely adapting themselves to circumstances more and more, and troubling themselves less and less about importations from anywhere; and certainly those who trouble the least, and work on the most intelligent lines, appear to be the most successful.

Relative to the resuscitation of the ancient practice of growing Apples and Pears on their own roots, we have nothing to say at present beyond our readiness to publish records of experience from home or colonial cultivators.]

PREVENTION OF THE CARROT MAGGOT.

IN many gardens it is almost impossible to grow good Carrots on account of the grub which so persistently attacks them. Such has been the case for several seasons at Craggside.

Last year an old man who had been successful in growing Carrots advised Mr. H. Hudson to try "Sunlight" soap as a preventive, the plants to be syringed once a week during May and June, at the rate of 8 gallons of water to 1 lb. of soap.

In the first week of August last I saw the Carrots growing in the gardens at Craggside to which the mixture had been applied. A finer and healthier crop it would be impossible to see.

In the month of September, at the Alnwick Horticultural Society, Mr. Hudson exhibited samples of the same Carrots, with which he won the first prize. The specimens shown were remarkably well formed, clean, and beautiful.

As this prevention is easily applied, and not costly, it is to be hoped many readers of "our Journal," in different localities, will test it during this season, and report later on.

Many of them use "Sunlight" in other ways, as it has been advertised in these pages, and it will please them still more if it help them to secure clean crops of Carrots. It should be tried also against the Onion maggot. The great thing is to act in time.—N. N.

FREESIAS OUT OF DOORS.—I am sending you a few Freesias that have been grown outside. The bulbs were planted last September on a south border, and have not been protected in any way from frost. I cut my first blooms on the 5th of December, 1898, and I daresay I shall be able to cut the last about the end of the present month. Of course the earlier ones were grown under glass.—ARTHUR LEWIS, *Cappoquin, co. Waterford*. [The spikes sent by our correspondent were producing numerous flowers of excellent substance and delicious fragrance.]

RECENT WEATHER IN LONDON.—Again we have to record sunny days and cold nights from Saturday until Monday evening. There have been frosts on one or two occasions. On Monday night a little rain fell, and Tuesday was very dull and rather cold until late in the afternoon, when the sun shone for a short time. Wednesday opened under the same conditions as the previous day.

— WEATHER IN THE NORTH.—No great improvement has taken place in the weather during the week ending 8th inst. On several nights sharp frosts have occurred with heavy rime, and this, followed by the bright sunshine of most days, is telling adversely on vegetation. Cold easterly winds have prevailed throughout the week, with intense cold, especially on a few evenings.—B. D., *S. Perthshire*.

— ROYAL HORTICULTURAL SOCIETY.—SCIENTIFIC COMMITTEE.—Present: Dr. M. T. Masters (in the chair); Prof. Church, Mr. Sutton, Rev. W. Wilks, Rev. G. Henslow, Hon. Sec. *Cattleya malformed*.—Dr. Masters exhibited a blossom having only one petal, one sepal, and a straight column. This reduction to a symmetry of "two" is not uncommon in Orchids. *Parasitic fungi*.—Some interesting communications with specimens of *Polyporus ulmarius*, showing how it appears to decay the interior of the tree and fructifies in the hollow, were sent by Dr. Plowright; also descriptions of parasitic fungi on Alders and Willows. They will appear in the "Gardeners' Chronicle." A vote of thanks was given to Dr. Plowright for his communication.

— WOOD ASHES.—In Mr. Cecil H. Hooper's article on manures, on page 334, he observes that wood ashes contain from 5 to 7 per cent. of potash and 2 per cent. of phosphoric acid. I am very pleased to see that phosphoric acid is recognised as one of the manurial items in wood ashes, as I do not remember ever seeing it mentioned before in any works on manures or chemistry. I consider wood ashes a valuable manure for gardens, both outside and for potting purposes inside, more especially for light soils, as it helps to cement the sandy portions together, which prevents too rapid evaporation; and this, of course, is in addition to its value as a manure.—J. L.

— AN ORCHARD HOUSE.—A few days since, when I looked through a long lean-to house in two divisions, and nearly filled with Plum and Cherry trees in pots, on all of which good crops were set, I could but realise the value of such houses during a season like the present, when even such well protected fruits as Peaches, and Apricots on warm walls outside were almost denuded of fruits, and sharp frosts and scathing cold winds were doing so much harm to other blooms. Yet this house was on the north side of a wall, and unheated. Whatever may be our fortune in relation to fruit crops outside, it is evident that, to be certain of securing fruit, there is nothing like having orchard houses in which to grow the trees. In this case all these were in pots, and there were numerous others plunged in leaves outside, intended to furnish well spurred trees for next year.—D.

— BEGONIA GLOIRE DE LORRAINE.—In the short time this plant has been in commerce it has found its way into numberless places, and is increasing in popularity by leaps and bounds. And no wonder, for it is one of the most beautiful winter-flowering plants imaginable, and one that may be cultivated in any greenhouse with proper attention. Those who have not rooted their young plants for next winter must not lose any more time, and those having the cuttings still in the store pots should have them potted singly without delay. Once starve them into flowering and it will be difficult to get healthy growth afterwards. An effective way of growing it is to put half a dozen cuttings into a 4-inch pot, and when rooted well, shift three or four of these potfuls entire into large hanging baskets. These will be well furnished by the autumn, and the effect in winter, when the whole of the growth is covered with the bright rosy blossoms, is very fine. Or, if pots are preferred, they may be given a shift into 6-inch or 7-inch before they get really root-bound, this being a capital way of getting fine plants for grouping. Even the smallest bit flowers freely and looks bright, while the effect of a large number of plants grown and flowered well, and tastefully arranged with Ferns, is unequalled by any other winter-flowering plant.—H. R.

— ROYAL HORTICULTURAL SOCIETY.—The next Fruit and Floral meeting of the Royal Horticultural Society will be held on Tuesday, May 16th, in the Drill Hall, James Street, Westminster, 1 to 5 P.M. A lecture on "Some of the Plants Exhibited," will be given by the Rev. Prof. G. Henslow, M.A., at three o'clock.

— BERBERIS STENOPHYLLA.—The pretty yellow blossoms have a very striking effect against the deep shining green leaves of this shrub, one of the best for planting in any collection of shrubs and flowering trees. The habit is very elegant, and, unlike many of this class of plant, it is not in the least fastidious as to soil. Planted a few years since on soil of the very worst description, and on a piece of ground where even grass would not grow, it is making fine bushes, and these are now wreathed with blossom. But it is worthy of far better things, and should be freely planted towards the front of shrubbery borders, or at the back of herbaceous beds of large size.—B. S. E.

— ONION NE PLUS ULTRA.—This monarch among Onions has on several occasions been referred to in the pages of the *Journal of Horticulture*. In our report of the meeting of the Royal Horticultural Society, held on April 18th, we failed to observe that it was recommended by the Fruit and Vegetable Committee for an award of merit. It was staged by Mr. L. J. Dunbar, seedsman, Hemel Hempstead, and is stated to be a seedling from Ailsa Craig and Carter's Record, the former of which it much resembles. It, however, is larger than that variety, and not quite so globular in form. It will be remembered by many readers that Mr. W. Fyfe, gardener to Lord Wantage, V.C., staged a bulb of Ne Plus Ultra at the Royal Aquarium last autumn, which weighed 3 lbs. 12 ozs. when harvested.

— MELON WILLIAM TILLERY.—I saw this handsome, free-cropping, green flesh Melon doing finely recently in a house at Ruxley Lodge, Esher. It is some thirty years since this fine variety was raised, and it shows how good and true a Melon can be kept for so long a period, that it is so remarkably good now. Mr. Miller, the gardener, raised it when at Worksop Manor with the previous Lord Foley, and named it in honour of his old and greatly esteemed friend William Tillery, who was then at Welbeck. Mr. Tillery much appreciated the compliment, and a good old gardener was thus complimented by becoming sponsor to a splendid Melon. Were this variety now sent out as a seedling with a new name it would no doubt receive a high award. As it is, it is one of the very best green fleshed Melons in cultivation, and Mr. Miller is to be complimented on having the fruit so true.—A. D.

— POLYANTHUS JOHN WILKINSON—CROWN IMPERIALS.—Mr. Joseph Oliver writes:—"I am very pleased to see that John Wilkinson Polyanthus has given such satisfaction to Mr. Arnott. Upon one of our plants I counted the other day twenty-four fine trusses. We have never been without some bloom on it all the winter. What a fine plant the old Crown Imperial Lily is when well grown. We have some that have not been replanted for many years, and no one would take any notice of them; but one plant in front of our window is simply grand; it only wants 3 inches to make it 5 feet high. Seven large flowering stems, crowned with their candelabra-looking heads, command attention. It is the result of one good bulb planted four years ago among good stuff. Bees and flycatchers patronise it amazingly." Mr. Oliver further observes:—"We are having very cold ungenial weather—4°, 5°, 6°, and this morning (8th inst.) 7° of frost, and white with rime everywhere."

— OUTDOOR APRICOTS—SUCCESSFUL FRUITING.—I consulted Mr. Rivers when getting a couple of Apricots for a sunny south wall in my garden some four years ago, and he recommended Early Moor Park. Since then, though the growth has been healthy and the wood well ripened, I had in no year more than half a dozen fruits, or less. I was consoled by being told if I had a crop once in seven years I would be lucky. To-day I did a considerable thinning of fruits, many half an inch in diameter, and think more than one hundred still remain on a single tree, covering 60 or 70 superficial feet. I attribute the success, outside the ordinary treatment, to two causes, which it may interest some of your readers to note. 1, I protected with a 20 foot board in February, 12 inches wide, over which I put ordinary fish netting, two folds of which draped down in front, so as to partially protect both from frost and sleet. More than two folds would exclude sun and light from the foliage. 2, Of more importance perhaps, was a partial lifting of the fibrous roots in front—not the tree itself—relaying of them in fresh loam, and building a heap of manure, which heated slightly, over them, and about a yard from the base of the tree. I should have said the protection is also over a Nectarine, which, although not so fruitful, promises a fair crop.—W. J. MURPHY, *Clonmel*.

METEOROLOGICAL OBSERVATIONS AT CHISWICK.

No rain has fallen since the 29th ult. The weather has been rather dull with cold winds and very sharp frosts on the mornings of the 4th, 5th, and 6th inst.

— **APRIL WEATHER AT HODSOCK PRIORY.**—Mean temperature of the month, 46.6°. Maximum in the screen, 62.8° on the 1st. Minimum in the screen, 27.2° on the 18th. Minimum on the grass, 15.1° on the 18th. Number of frosts in the shade, five; on the grass, fifteen. Sunshine eighty-six hours, or 21 per cent. of the possible duration. Rainfall 2.08 inches; difference from the average, + 0.34. Rainy days, eighteen. Maximum fall, 0.35 on the 9th. Rainfall from January 1st, 6.28 inches; difference from the average, + 0.57. Dull unsettled and showery month, no really warm day.—J. MALLENDER, *Workshop*.

— **APRIL WEATHER AT DOWLAIS.**—Rainfall, 6.26 inches, which fell on twenty-one days; greatest fall, 0.88, on the 6th. Temperature, mean maximum, 51°; highest reading, 61°, on the 18th. Mean minimum, 34.3°; lowest readings, 25°, on the 16th and 17th; below freezing point on thirteen nights. The wind was in the S.W. and W. on twenty-three days. There were fifteen sunless days. A very rough, wet, stormy month, which has thrown the outdoor work much behind. There were heavy falls of snow on the 20th and 21st, and very strong winds were general throughout the month.—WM. MABBOTT.

— **EARLY PLANTED POTATOES.**—I have been wondering what effect has been produced on the very early planted Potatoes in exposed areas by the recent sharp frosts. Naturally we expect to find that where unprotected the tops have been cut to the ground, or even lower; but whether having learnt wisdom from experience, or for other reasons, I do not find that Potato planting generally has been so early this season as it has been in some previous years. Except in very sheltered places, and even then where some form of covering can be furnished at night, there could not be any gain in planting sets so very early. None of my planting, and that refers to a considerable quantity in various places, were put in early enough to get through before the middle of May, and I trust ere then all danger from frost will be over and the plants will grow unharmed.—A. KINGSTON.

— **STOCKS FOR FRUIT TREES.**—I am of the same opinion as Mr. Lambert (page 314) regarding the value of Paradise stocks for Apples growing in the open field where size of tree and quantity of fruit is the first consideration. If trees worked on the Paradise stock become what is known as "stunted" through poverty of the soil, they are most difficult to re-start. My experience teaches me never to plant an Apple tree worked upon a Paradise stock if free growth is required, especially if the soil is heavy, but for a limited space, light soil, and constant attention in supplying stimulative food, this stock might satisfy. Mr. Lambert omits what is, in my opinion, the best of all stocks—viz., the seedling or free stock obtained from the pips or seeds from the cider mills. Some growers object to it on the ground of too vigorous growth, and consequent shyness in bearing, but the latter charge is unfounded, as I have proved by experience gained from several hundred trees. Take Lord Grosvenor for example. This variety is naturally a strong grower, yet it will give a crop of fruit the year after planting, if required, on the free stock. Surely this cannot be termed shy bearing. I agree with Mr. Lambert in his remarks anent the failure of the Myrobalan stock to oust Quicks or White Thorn as a hedge plant. I have been watching a hedge of it for the last five years, and from its progress I should hesitate to recommend it to anyone or to plant it myself.—E. M.

— **ROYAL METEOROLOGICAL SOCIETY.**—At the ordinary meeting, to be held in the rooms of the Society, 7C, Victoria Street, Westminster, S.W., on Wednesday, the 17th inst., at 4.30 P.M., the following papers will be read:—"The Mean Temperature of the Surface Waters of the Sea Round the British Isles, and its Relation to that of the Air," by H. N. Dickson, F.R.S.E., F.R.Met.Soc.; "Some Phenomena Connected with the Vertical Circulation of the Atmosphere," by Major-General H. Schaw, C.B., R.E.

— **PIPTANTHUS NEPALENSIS.**—Better known as the Evergreen Laburnum, this fine spring-flowering shrub should be more generally grown, as the glossy green foliage and golden yellow flowers are striking and handsome. The plant requires a warm situation with shelter from cold winds, or the foliage is apt to be browned at the tips. It may be propagated in autumn by cuttings of the half-ripened shoots, these rooting freely if kept moist under a hand-light or by layers, the latter plan being preferable where only a few plants are needed. It likes a rich sandy soil.—C. H.

— **TRILLIUM GRANDIFLORUM.**—The American Wood Lily is a splendid plant for working in large pans or pots in a greenhouse, yet how seldom it is seen. I recently noted several large pans full, and the rosy white flowers had a very beautiful appearance upon the bright fresh-looking foliage. The plant does best in a very moist soil containing a good percentage of peat, and these individual plants are grown in peat and bog moss, with only a little loam. During the time the growth is active ample root and atmospheric moisture are essential, and to preserve the foliage careful shading is necessary.—T. G.

— **CHOISYA TERNATA.**—Reference is made on page 297 to this evergreen as a useful pot plant. But to see it in its glory is, put out a strong plant at the foot of a south wall in deeply dug and well manured soil, where it will quickly grow into a handsome bush. Train the bulk of the branches to the wall until, say, 5 feet in height has been covered, then allow it to grow at will, thus forming a dense bush. Give plenty of water during the summer while growth is being made, and every year during the month of May the plant will be smothered with its pure white blossoms, backed by dense green leaves.—E.

— **POTATO UP-TO-DATE.**—What a pity this handsome free-cropping Potato is not of better cooking quality. I am aware that from various soils the conditions differ, but speaking of examples tasted from several sources, I am driven to the conclusion that for quality this variety is second-rate. This is the opinion also of men who grow it by the acre, but who also know its selling qualities, and act accordingly. Not only is it almost black when cooked, but it has an offensive smell, as well as a disagreeable taste. In spite of this I am giving it an extended trial beside of my favourite main crop variety, White Beauty of Hebron, of which I have 5 acres.—E. MOLYNEUX.

— **RHUBARBS.**—It has recently been urged that Rhubarb should be more raised from seed, less dependance being placed on divided plants and old stocks. It is probably because we have preferred to rely so much on such propagated stocks, that we have so very few good Rhubarbs in commerce. It is true there is a large collection of these plants at Chiswick, almost the only garden in the kingdom where many of them may be found. But after all, two or three selected as the best suffice for all purposes, for Rhubarb stems differ little in flavour or texture on the average, except, of course, that the younger and smaller ones are of more succulent nature than are old and large ones. But whilst our best two Rhubarbs, Hawkes' Champagne, the popular early market variety, and apparently found under other designation, seems to be the best for colour and earliness, there is no better average main crop form than is the Victoria. But were Hawkes' Champagne rather larger in stem its value would be enhanced, and were Victoria much more richly coloured it would be great gain, for there can be no doubt but that in Rhubarbs colour is a valuable marketable commodity, and enhances flavour. The seedling variety from Victoria, which Mr. G. Wythes placed before the Fruit Committee at the Drill Hall on the 2nd inst., had all the size of the parent, and nearly the rich colour of Hawkes' Champagne. That variety well merits increase, because it is an advance in the right direction. It will be great gain if anyone can give us a finer Champagne, and if possible even an earlier one. Rhubarb in the earlier part of the year is in immense demand, and is very expensive. Even when pulled and bundled from the open air, the bundles are often sold at 6d. each, and they contain one-half rubbish. It is not to the credit of growers that such stuff be foisted on the public. It is only inviting better consignments from other lands. Market men of high repute are careful in their packing.—A. D.

TOMATO WINTER BEAUTY.

MANY persons will be of the opinion that we have a sufficiency of Tomatoes in cultivation at the present time, and for summer cropping there is certainly a great supply of varieties not easy to excel. When, however, it becomes a question of producing heavy crops in the early spring months several of the most popular varieties do not render a particularly good account of themselves. It was as a superb winter fruiter that Winter Beauty, when exhibited at the Drill Hall by Mr. S. Mortimer of Rowledge, was given an award of merit by the Fruit Committee, who would probably have recommended a first-class certificate had two or three fruiting plants accompanied the boxes of specimens. On page 370 "A. D." gave an excellent description of this Tomato at home, and we cannot supplement those remarks better than by reproducing a photograph of a portion of one of the houses, which was taken on April 28th last. The new comer, as possessing earliness, productiveness, colour, quality, and size, may be expected to find its way into many gardens.

IXORAS.

(Concluded from page 356.)

AFTER cutting back the plants should have gentle bottom heat to induce them to start freely into growth, and the top heat ought to range from 65° to 70° by artificial means. They must be very carefully watered and syringed. If given bottom heat they will require next to none of either, for the moisture given off by the fermenting material and that resulting from damping surfaces as they become dry will be sufficient in most cases. When such is not the case very lightly sprinkle, and keep the soil just moist.

After the plants have started into growth, any potting that is needed should be done. The plants are very impatient of disturbance at the roots, hence are potted with the ball entire—that is, with the crocks only, and any loose soil is removed. Large shifts must not be given, a little fresh soil under, around, and over the ball being sufficient. This may range from half an inch to 1 inch, according to the vigour of the plants, always using the compost rough for established plants, and if possible return to bottom heat.

The plants must be carefully watered. They can hardly have too much heat and moisture in summer, and the less they are syringed the better, as the water often spoils the foliage, which is not the least attractive part of the plant. A little weak, clear liquid manure benefits during the growth of the plants and development of the trusses of bloom. The heat should be 65° to 70° at night, 75° by day from fire heat, and 10° to 15° or more from sun heat. Damping in the morning soon after midday, and again in the evening, will supply air moisture. Moderate ventilation is imperative, as the plants enjoy a change of air without sudden fluctuations or depressions of temperature.

The Ixoras are evergreens. They do not admit of the drying off process, but it is astonishing what a long time they will go in winter time without water. In a bed of fermenting materials they, like Pine Apples, need very little water at the dead season. In other cases the soil must just be kept moistened sufficiently to keep the foliage fresh. That is all the resting they require, with a lessened amount of air moisture and cooler atmosphere. This in the autumn and winter may range from 55° to 60° as a minimum, and about 5° more from fire heat in the daytime. The ripening of the wood is essential to the production of flowers, well matured growths being more prolific than soft and immature wood.

The species number over a hundred, and the varieties are numerous. Some of the most desirable, of which the choicest have an asterisk, are—

I. acuminata.—This has white flowers; fragrant, large; corymbs decomposed, crowded, almost sessile; height 3 to 6 feet. India.

I. coccinea superba.—The flowers are deeper coloured and broader and thicker in the petals than those of the species; bright red, disposed in very large heads or corymbs, which are umbellate. It also grows more vigorously than *I. coccinea*, which is, perhaps, the more elegant plant. *I. c. superba* is from Java, and *I. coccinea*, syn. *I. grandiflora*, from the East Indies; height 3 to 4 feet.

I. Colei.—Flowers white, produced in large round corymbs, leaves deep green and roundish; plant strong, free and robust growing. A cross between *I. coccinea* and *I. stricta alba*.

I. Dixiana.—Flowers dark orange, borne in very large corymbs; plant of a hardy constitution and free-flowering habit. A seedling form.

I. floribunda.—Flowers reddish-scarlet, produced in large dense corymbs, plant of robust growth. A garden variety.

I. Fraseri.—Flowers brilliant flamed salmon colour, borne in numerous, terminal, globular corymbs; foliage dark green; plant of free and vigorous growth. A beautiful garden variety.

I. fulgens, syn. *I. salicifolia*.—Flowers orange-scarlet, produced in dense terminal corymbs; height 3 to 4 feet. Java.

I. javanica.—Flowers orange, borne in dense corymbs on long peduncles; height 3 to 4 feet. Java.

I. macrothyrsa, syn. *Duffi*.—Flowers deep red tinged with crimson, produced in immense trusses; leaves deep green. A fine plant. South Sea Islands.

I. odorata.—Flowers pure white, changing to yellow-brown, and very fragrant, produced in large terminal clusters or panicles 1 foot or more in diameter; height 3 feet. Madagascar.

I. Pilgrimi.—Flowers orange scarlet shaded with crimson, borne in round corymbs about 6 or 7 inches in diameter; plant with a good hardy constitution, and, like its parent *I. Williamsi*, not so exacting of heat as *I. coccinea* and most others.

I. Prince of Orange.—Flowers cinnabar-red, borne in compact heads; plant free and vigorous in growth. A fine garden variety.

I. princeps.—Flowers buff white, changing to deep reddish orange, produced in the greatest profusion; a fine species. Java.

I. regina.—Flowers violet salmon, borne in large dense corymbs. A dwarf, compact growing, handsome garden variety.

I. sanguinea.—Flowers crimson, shaded with deep violet, produced in large dense corymbs; foliage deep green. A garden variety.

I. stricta (crocata).—Flowers light orange, borne in many-flowered cymes. Height 2 to 3 feet. Moluccas.

I. s. rutilans.—Flowers rich orange, produced in compact heads; plant freer and more vigorous in growth than the type.

I. Williamsi.—Flowers reddish salmon, in large heads; plant of a free-growing and profuse flowering habit, and requires somewhat less heat than most of the other species and varieties.—G. ABBEY.

THE STUDY OF NATURE.

And this our life, exempt from public haunt,
Finds tongues in trees, books in the running brooks,
Sermons in stones, and good in everything.

WHAT perfect contentment! ah, and what pleasure too is expressed in these words of the exiled Duke in "As You Like It." Though far from the busy haunts of men, amid the solitudes of the Forest of Arden, to him the philosophical aspect of the commonest things was apparent. There must be hundreds, probably thousands, engaged in horticultural pursuits, similarly situated, "far from the madding crowd." Would it not be well if these could find a like solace and consolation in observing with intelligent interest the marvels that the various natural phenomena supply?

The smallest flower

That twinkles through the meadow grass, can serve
For subject of a lesson; aye, as well
As the most gorgeous growth of Indian climes;
For love of Nature dwells not in the heart
Which seeks for things beyond our daily ken
To bid it glow.

What Tennyson has called "the fairy tales of science" are within the reach of all, but, alas! how few there are, even among gardeners and nurserymen, who understand the language of the trees; read the books mysteriously hidden in the recesses of the running brooks; hear the sermons discoursed for ages by the rocks and soil, or realise the beauty and perfectness of all things; the unspeakable delight of studying Nature in her own domain.

Leigh Hunt, in one of his essays, when speaking of the least esteemed of the commonest plants, exclaims, "What a quantity of life, and beauty, and mystery, and use, and enjoyment is to be found in them, composed of all sorts of elements, and shaped as if by the hands of fairies." Coleridge said that poetry had soothed his afflictions, multiplied and refined his enjoyments, endeared solitude, and given him the habit of wishing to discover the good and the beautiful in all that surrounded him. The endeavour to describe these emotions exerted his intellectual activity, and gave him pleasure when perhaps nothing else could.

We are not all possessors of the "divine afflatus," but our better nature will develop in the same degree as the poet's if we strive to hold a closer communion with the animate and inanimate creation which comes within our daily ken. Study of this kind draws us from all that is sordid; we live for the time being in an earthly paradise; our musings and imaginings take us out of ourselves and "lend wings to our dreams." If the external beauty of plants had this charm for us; if the meanest flower that blows could enchant us with its form and colour, we should not be satisfied until we were familiar with its structure and functions.

It is not unusual in a semi-rural neighbourhood to see in early spring the first fresh green leaves of the trees wantonly destroyed—many "sunny spots of greenery" strewn with the mutilated branches, as if their renewed growth was an insult to the passer-by. The owner of the pitiless whip or stick that works such havoc sees no beauty in these banks of green, for a devoted attachment to the works of Nature is an evidence of delicacy and refinement. This destructiveness, which often exists in the young bucolic mind, is due, not to the want of pleasures, but to the inability to select and enjoy those already possessed. Familiarity in this, as in so many cases, breeds contempt,

so that material things without the light of science to reveal and unfold new wonders, become purely utilitarian—the tree is so much firewood, simply this and nothing more.

To quote Leigh Hunt again: "Suppose flowers themselves were new. Suppose they had just come into the world, a sweet reward for some new goodness, and that we had not yet seen them quite developed; that they were in the act of growing; had just issued, with their green

With the rejuvenescence of Nature at the present time—the trees and fields clothed in masses of blossom and greenery, and every hedge-row and meadow starred with spring flowers—let us commence our study of Nature. We shall be in good company, for men of great abilities have spent their lives in the observation of small things. Let us be encouraged with the thought that the flowers will become more beautiful with the knowledge of their structure, the scent more

FIG. 83.—TOMATO WINTER BEAUTY.

stalks, out of the ground, and engaged the attention of the curious. I imagine what we should feel when we saw the first lateral stem bearing off from the main one, or putting forth a leaf. How we should watch the leaf gradually unfolding its little graceful hand; then another, then another; then the main stalk rising and producing more; then one of them giving indications of astonishing novelty—a bud! Then this mysterious bud gradually unfolding like the leaf, amazing us, enchanting us, almost alarming us with delight." On reading such a passage we are inclined to say with Whang the Miller, "Oh! that I could dream like him!"

sweet when we know the method adopted by the plant for its dissemination.

No greater treasures can be offered to human desire than enjoyments such as these, which at once exercise the mind and improve the heart, repel the influence of sordid passions, and encourage the suggestions of humanity, virtue, and religion. By observing the processes constantly going on around us, the physical properties of matter and the mutual relations of organised beings are far more effectually understood than when learned from descriptions in books, without the aid of observation or inquiry.—F. S. H.

PROGRESS IN FRUIT PRODUCTION.

(Continued from page 323.)

IN consequence mainly of the interesting matter on pinching fruit trees occupying, and worthily so, a considerable amount of space in our two last issues, the publication of the following extracts from Mr. W. Bear's comprehensive paper in the "Journal of the Royal Agricultural Society of England" has been postponed.

FRUIT IN THE EVESHAM DISTRICT.

"Forty years ago Potato growing was the great industry at Evesham, and very little fruit was produced there; but during that period, and mainly within the last twenty years, fruit planting has been constantly extending, and now there must be considerably over 1000 acres within a few miles of the prosperous little Worcestershire town. The rent of market garden land close to the town before being planted with fruit is £4 to £5 an acre, while planted land is worth £8 to £10 per annum, but these rents are charged only when the landlord originally planted the trees, or has bought up the tenant's right in them; for an interesting system of tenant-right prevails in the Evesham district, under which a quitting market gardener or fruit grower sells his interest to a successor approved by the landlord, either at the old rent or at an altered one agreed upon by the landlord and the new tenant.

"It is satisfactory to learn that fruit growers in the district are generally prosperous, and vegetable growers likewise; many get a living from 5 acres of fruit trees and the crops grown between and under them, working themselves and employing four or five men also. Twenty acres of fruit are considered as making a large business in Evesham, and no one, so far as I can learn, has over 30 acres of fruit alone. At a few miles distant, however, and in the neighbourhood of Salford Prior, fruit plantations are larger, and one grower has about 100 acres. The labourers earn fair wages for a place in the midst of a great agricultural neighbourhood. In Evesham they get 17s. a week, and in parishes just outside 16s. Women have 1s. 6d. a day, but work mostly by the piece."

"Mr. H. Masters, one of the most extensive fruit growers, stated that the most important fruit crop in the Evesham district is the Egg (or Pershore) Plum, and the next (in Evesham, but not so much in the outlying parishes), the Damascene or Worcester Damson. Apples rank next in importance among tree fruits, and then Cherries, Pears not being grown to a large extent. The great size and flourishing condition of the old Plum trees in the district are remarkable, and the suitability of the soil and climate to this fruit is further shown by the long life of the trees. Mr. Masters has some giants nearly forty years old, and still full of vigour. He has six or seven pots of (72 lbs.), or 430 lbs. to 500 lbs., off a single Damascene tree in a very prolific season. The Victoria is most commonly grown, next to the two varieties mentioned; after which come Rivers's Early Prolific, New Orleans, Czar, Cox's Emperor, and Monarch. The Gooseberry is by far the most important bush fruit in Evesham. Strawberries are not grown upon a large scale, though a great many market gardeners have small pieces. Mr. Masters has 8 acres, and last year 16 tons were gathered from 2 acres, besides a quantity of waste. The crop is a somewhat uncertain one; but, when 8 tons per acre are produced, it must be an extremely profitable one. Probably such a yield is rare. Young fruit trees are pruned in the autumn and winter; but after a few years they require only a little trimming to keep them in shape. The manures used for fruit are chiefly soot, fish guano, blood manure, and phosphates. Basic slag is coming into use as a phosphatic manure.

THE PERSHORE FRUIT DISTRICT.

"The Earl of Coventry, as President of the Royal Agricultural Society, kindly interested himself in my investigation of the fruit industry, and invited me to visit his Croome Court Estate, in the Pershore district of Worcestershire. Under the obliging guidance of the Earl's agent, Mr. Hill, who gave a great deal of information about the district, a visit was first made to the jam factory, close to Pershore Station, established and worked for a few years by Lord Coventry for the benefit of his tenants, but now in the hands of Messrs. Beach & Son. The factory is small, but well appointed, and everything was found perfectly clean and conveniently arranged. Jam making was finished for the day, but fruit was coming in for the following day's work. Mr. Beach, jun., said that in consequence of the abundance of Plums in the district he expected to be able to obtain them for 2s. 9d. or 3s. per pot of 72 lbs., instead of 9s. to 10s. paid in the previous year; but it is doubtful whether they came down to such low prices during the season, and Mr. Cosnett, one of the Earl of Coventry's tenants, made 16s. 6d. per pot as a starting price at Birmingham for Early Rivers. Mr. George Jones has an excellent fruit plantation at Pinvin, close to the jam factory. Seven acres of the plantation are occupied by Gooseberries as bottom fruit, and 530 pots (17 tons) had been picked off that area, while enough remained as ripe fruit to make up an average of 2½ tons per acre.

The principal varieties are Crown Bob for selling early, Whinham's Industry, Lancashire Lad, Keepsake, and a few Warringtons for ripe fruit, for which Lancashire Lads also are held over to some extent. Some of the bushes are twenty-three years old. Others planted only three years before the past season, when they were a year old, had a tremendous crop. They bore fairly in the second year. These were Lancashire Lads. Over 200 pots of Whinham's Industry were picked off 1 acre, and none of them sold at less than 4s. a pot, so that the return on this acre for bottom fruit alone was over £40.

"Mr. Cosnett said his crop of Gooseberries was the biggest he ever saw, and his years are not few. He had picked about 200 pots of Whinham's Industry from an acre. This would be nearly 6½ tons, an enormous quantity. The bulk had been sold at £7 a ton. Mr. Cosnett was afforded an object lesson as to the harm done by putting grease on to the trunks of trees without bands before he had learned the danger of so acting. The trees were badly injured.

"There was much to see at Croome Court and in the grounds besides the fruit plantations, including a beautiful kitchen garden of extraordinary size. The Earl of Coventry was good enough to show me many objects of interest, and to accompany me to the fruit plantations, 40 acres in extent. They consist of Plums and Apples, planted alternately—a very good plan—with Black Currants as the only bottom fruit, as less liable to the depredations of birds than Gooseberries or Red Currants. As the plantations are isolated this is an important consideration. The trees and bushes presented a very prosperous appearance. The fruit is sold by tender as it grows, buyers to do the picking. Mr. Hill in this way once sold for Lord Coventry three-quarter acre of Plums and Apples for £70, and he knew of a case in which 1½ acres sold for £90. Both sales took place some years ago. Lord Coventry is fortunate in not being troubled with the Black Currant mite, his immunity being due to the isolation of his orchards. There are between 200 and 300 acres of fruit on the estate.

FRUIT GROWING AND PRESERVING IN ESSEX.

"Although Essex is not a great fruit county orchards have increased by nearly 1000 acres since 1878, and the small fruit by about 1300 acres since 1888. In that county, moreover, one of the most striking instances of a farmer becoming a successful fruit grower is to be found. In 1862, Mr. A. C. Wilkin of Tiptree Heath, near Kelvedon, occupying the next farm to the late Mr. J. J. Mechi, came to the conclusion that Wheat growing was not likely to pay, and therefore turned his attention to fruit growing. He began on a very small scale, planting only 2 acres of Strawberries. The plants cost no less than £25, and were difficult to obtain even at that high price, as existing growers did not care to supply a new competitor. However, Mr. Wilkin increased his fruit area every year, and in 1885 he built his jam factory. In 1887 the business was transferred to a limited company, called the Britannia Fruit Preserving Company, with a share capital of £13,500, Mr. Wilkin owning more than half the shares, and being made managing director. At present two of his sons are the only other directors, and a third son is secretary. Since that date the acreage of fruit has been increased to 260 acres. There are 165 acres of Strawberries, 43 acres of Raspberries, 30 acres of Black Currants, and small areas of Red Currants, Gooseberries, Plums, Damsons, Greengages, Apples, Quinces, Blackberries and Cherries, some of the bush fruit being on the same ground as trees. The soil is a stiff loam over what Mr. Mechi used to call a "bird-lime" subsoil, and Strawberries flourish upon it magnificently. The Small Scarlet Strawberry, descended from the wild alpine, is a speciality at Tiptree Heath, no less than 55 acres being devoted to it, as it makes the best of jam. The crop of this variety seen on July 5th was the finest inspected anywhere during my wanderings through some of the principal fruit districts. There were two rows only on an eight-furrow stretch, this Strawberry being of a spreading habit, and the plants stood up high above the ground covered with the small and brightly coloured berries. Fair crops of Paxton and Royal Sovereign were also seen, the few Nobles grown having been gathered. Picking was in full swing, over 400 persons being employed, with a dozen gangers to superintend. The prices usually paid for picking are 1d. per 3 lbs., or 4 lbs. for the large varieties, and 1d. per lb. for Small Scarlets. Men earn 4s. to 7s. a day at picking, and Mr. Wilkin has known a man to earn 10s. in a day. Women and girls are also largely employed. Women do not pick as much fruit in a day as men, but do the work more carefully. Mr. Wilkin sells fruit when it is dear, and he made 10s. a peck of his earliest Royal Sovereigns. Strawberries yield well when two years old, and stand for six or seven years on this farm.

"No pulp is made in the factory except when there is a glut of fruit, and then only for the 'household jam,' which is distinguished from the 'whole fruit conserves,' and sold at lower prices. Moreover, rapidly perishable fruit, such as Strawberries and Raspberries, is never held over for a day when intended for whole-fruit preserves. The picking of Strawberries starts at 4 A.M., and the first lot is made into jam by 6 A.M. About 200 tons of jam are made in a year, including about half the fruit grown by the company, and some fruit purchased,

amongst it Apricots from California, Italy, France, and Spain. There are eleven steam-jacketed vats to hold 70 lbs. each, and two to hold half a ton of syrup each, which were in use at the time of my visit. The 70 lbs. vats are not half filled in jam-making, only about 28 lbs. being put into each, as the jam is better when made in somewhat small quantity. The syrup, simply sugar and water, after being boiled, is first placed in the vats, and the fruit is added afterwards. The heat is regulated by thermometers, and can be raised if desired to 225° F. Strawberries require to be boiled for only seven minutes, and very ripe fruit for only four, while Gooseberries and some other kinds of fruit need more time. The scum is thrown away, and the scrapings of the vats are not allowed to go with the whole-fruit conserve.

"In 1889 Sir Walter Gilbey commenced to grow fruit on a small scale on his estate, Elsenham Hall, Essex, by way of example to his tenants, cottagers as well as farmers, and in 1893 he started a jam factory. To encourage the cottagers he has granted pieces of land close to their dwellings rent-free, and provided Strawberry plants for those who required them, on condition that they send their fruit to the factory at market prices, and it is not surprising that a good many avail themselves of this advantage. Jam is made quite in the home method, except that steam and thermometers are used. That is to say, fruit, excepting some of the Strawberries, is simply boiled with the best leaf sugar. The only fruit boiled in syrup previously prepared is the Strawberry for whole-fruit jam. Raspberries are boiled only six to seven minutes, but Strawberries longer. In bottling Gooseberries, the fruit is put into the bottles, which are then wired down, and placed in cold water, to be gradually heated by steam and kept at a temperature of 180 F. for about two hours.

(To be concluded.)

WRINKLES.

"WRINKLES, indeed! As if there were not enough already upon the brow of care." It is admitted; in fact it "darna be disputed" when one thinks of spring frosts pouncing down on the early Potato, and blackening tender blossom in the silent watches of the night. Oh! the perversity of Nature! Even the great poet must have had an inkling of such matters malignant when he said, "Rough winds do shake the darling buds of May;" but there is a little incentive admonition in the information that "Our remedies oft in ourselves do lie which we ascribe to Heaven." This "darna be disputed" either. There are, of course, wrinkles and wrinkles, and some of the little ones proffered, or asked for here, may smooth away a few of the big kind.

Preparation is half the battle; timely application giveth the victory. I served under one old gardener who rigidly insisted upon the usual nightly covering up, independent of weather, till the end of the "merrie month." To us of the bothy it was sheer vanity and vexation to our young spirits. To some extent we were right, for discrimination will three times out of four discern the shadow of coming events, and for the doubtful fourth always make ready. But there must be no margin for errors of judgment, or hasty conclusions at night may bring sorrowful reflections in the morning.

Twenty-five years since, in a large garden where Potatoes were a good gardener's pride, came a cry in the "wee sma' hours," "Up lads and man the fire engine, or the Potatoes will be all burned." The cry of frost was as thrilling to us as the cry of fire, so we "up" and at 'em—trundled out the cumbersome antiquity kept in a coach-house near at hand, coupled on the hose, and worked with a will while the "gaffer" sprayed a long border, and a large plot as well, ere Sol's rays could work mischief. They were the only Potatoes unscathed in that locality, but I must admit it was the only fire engine too. However, it is surprising what can be done with a garden engine, syringe, or even a waterpot and rose to quench the "burning." It is an old-fashioned remedy, and perhaps worth remarking that years farther back than then I helped to drench the plants in a greenhouse which had, through a breakdown, been frozen stiff in the pots. In this case the house was darkened by mats, blinds—anything to hand; and for several sharp nights following the frost was kept out by a few candles kept burning. Results exceeded expectation, and I was impressed by the value of the remedy.

I do not know of any phase of work in which the old aphorism "necessity is the mother of invention" is more relevant than to that of gardening, or of any men better able to emphasise it than gardeners. I think young fellows are the better for having served under men who can show them how prompt action springs from dire necessity. Who shall tell what a night may bring forth? None, truly; but there are not wanting those who think it expedient to inquire of Nature herself what little surprises she may have in store. Bright skies with a high midday temperature are not uncommon at the end of May; but a passing cloud from afar patters down the merry little hailstones, telling of a cold strata ready to descend at midnight. Or, it may be, on the distant horizon a dark cloud with ominous streaks descending

gives portentous signs. It is hail. There is no mistaking it by the watchful eye, and when hail is about frost is at hand. "Oh! I'll chance it!" is a very common expression on a doubtful night from men to whom knowledge comes but wisdom lingers. "Short of mats." "Litter is untidy." "Didn't think it would freeze." Any amount of pegs in the garden handy for excuses, but necessity can provide some queer coverings, even to blankets off a curator's bed, but "that's another tale," as Mr. Kipling would say.

"The best gardeners are the biggest grumblers" has been said. The farther one goes in gardening, and the more one knows of gardeners, is any doubt of its relevancy removed. Anticipating what a season may bring forth, a spell of drought is met. "Just when I didn't want it; ground baked, can't get out the green stuff." Here is a wrinkle for it. Blend up fresh cow manure with water to the consistency of cream, and as the plants are drawn from the seed beds, dip in root and stem ere dibbling them into position. I have seen acres of Broccoli and Brussels Sprouts thus treated holding their own till the change came which sent them ahead. That charming feature of English gardening, the lawn, is often marred in rather important positions by bald spots under trees. Where this trouble is apparent now is a good time for sufferers to test what others have proved to be a remedy, even in bad cases. Sow grass seeds on the bare places, on a little fresh soil if the labour is not grudged, and sow liberally with the seeds some malt-combs, which can generally be obtained at any brewery. When the blades are fairly strong, dust more of the malt-combs through them and note the effect of this restorer on bald patches.

Now is a good time to think of the treatment of that popular plant, the Calla, for next winter's display. One who grows 2000 for market purposes gave me a wrinkle. He has found his method the easiest, the cheapest, and the best for producing fine spathes from autumn till mid-May. At the latter period his method is to plant them out rather thickly in a sheltered part of the garden, and in a fairly cool position, all double crowns being divided. From thence till September nothing more is done for them, when they are lifted and potted singly into 7 or 8-inch pots, according to size, and removed under cover. With a night temperature of 50° fine spathes are produced freely through the winter. Potted, as they are, in rather poor soil, an occasional sprinkle of chemical manure in the spring is beneficial, but stimulating liquids are vigorously excluded. One year only was the drainings from a "midden" given to the plants in February, resulting in a crop of gigantic leaves, with fewer and smaller blooms.

Chemical manures, such as are in general use for garden purposes, appear to be infinitely preferable for flowering plants; whereas the home-brewed liquid manures, or drainings of the "midden," seem better adapted for promoting leaf development and growth. This in relation to pot plants. Perhaps the often overfed Chrysanthemum may be included in the category, for troubles are not unknown in connection with the subject. *Apropos* of the common Calla, or *Richardia æthiopica*, is it generally known that there are two forms of it? My friend, "The Busy Man," who has done so well with it for years, first called my attention to the matter. The one he grows and swears by has a reddish tinge at the base of the leafstalks; the other he once grew, and swore about, I fear, is quite green without a suspicion of red. It is shy and generally unsatisfactory, or, as he puts it, "doesn't pay."

A wrinkle would be acceptable about Ivies. Some twenty years ago I planted a number of Ivies on a newly restored church in a country village, "far from the madding crowd." They consisted of three or four varieties, all green, the names of which I cannot give, but they were all more or less finely cut and particularly distinct in character. After an absence of some years I recently visited the spot, and found that they had not only grown apace, by reaching to the top of the edifice, but had also grown out of all knowledge, having lost all trace of birth or breeding, being just common Ivies, and no more. Can anyone elucidate the mystery? It may be added that I propagated them from cuttings, and that they were well rooted plants when planted; also that I saw them taking a good grip of the building ere the interregnum came.

How many times has the "varmint" raised a wrinkle anent newly sown Peas, in spite of drastic so-called remedies—Sweet Peas, culinary Peas, all sorts and conditions of Peas. Would one credit that mice could or would enjoy Peas soaked in petroleum, and liberally dusted with red lead? But it is another fact, stubborn though it be. Row upon row thus treated have been destroyed just as the seeds were bursting, and the "varmint" could shell them easily. There was nothing for it but to "trap 'em," and it was a good investment when two dozen "Delusion" traps (an American conceit) were bought and placed along the rows, with a few oats as bait. This trap, a self-setting one (I do not know if it is procurable now), would "catch 'em alive," six at a time occasionally, and often two brace of fat fellows were shaken out of one trap into a bucket of water to expiate their crimes. No trap we ever used was better proof that their schemes

"gang aft aglee." For rats a little sulphur paste on bread generally proves a quietus, as well as being a fairly safe remedy.

Peacocks have not much to do with gardening—for those who are not the happy (?) possessors of them. We have a couple, fed on a pound of good beef per diem, besides other addenda to their menu, and it seems just sufficient to brace up their appetites for a good square meal off the better class of hardy plants. These they go for "tooth and nail" till not a shred remains but the label. There is no wrinkle applicable here, I fear, save to those who contemplate keeping peafowl, then it takes the emphatic form of "Don't." There is an old superstition that these birds are unlucky. It is now part of the creed of—WRINKLER.

FRAGRANT GREENHOUSE RHODODENDRONS.

AMONG the many Rhododendrons suitable for greenhouse culture, those that go to make up the scented group are best known and most popular, for, while anything like a representative collection of species is rarely found, there are few gardens of any pretensions that do not boast some of those now under notice. The group consists of the following species, and a large number of hybrids which have originated from them:—*R. formosum*, *ciliatum*, *Edgeworthi*, and *Veitchianum*.

R. formosum is a very variable species; it is distributed widely in the Himalaya, and differs greatly in size and shape of foliage and flowers. The form usually met with has leaves 3 inches long by half an inch wide, and is of fairly compact habit. The flowers are 2 inches or more across, white inside, and suffused with rose on the outside of the corolla. Another well known form is that which is often called *R. Gibsoni*. The habit of this is looser, the leaves larger and more hairy, and the flowers of greater size. Others have still larger leaves, are very loose in habit, have the throat of the flower tinged with yellow, and are, if anything, more fragrant.

R. ciliatum is the hardiest of the group, and can be grown in the open air as far north as London if sheltered from cold winds. The leaves and young stems are very hairy. The flowers vary in colour on different plants, some being near those of the narrow-leaved *formosum*, others more creamy; the calyx in this, however, is well developed, which is not the case with the form of *formosum* it most resembles.

R. Edgeworthi has possibly been used more than any other by the Hybridist. In appearance it is very distinct. The leaves are from 3 to 4 inches long and more or less ovate, with recurved edges. The upper surface is very deeply veined, giving the leaf a wrinkled appearance, while the under side, as well as all the young wood, is thickly covered with a light brown felty pubescence. The flowers are very sweetly scented. They are borne in loose trusses of from two to four flowers each, and are from $3\frac{1}{2}$ to $4\frac{1}{2}$ inches across. The colour is white, with occasional faint marks of rose on the outside and pale yellow on the inside of the corolla. A figure of this may be seen in the "Bot. Mag.," t. 4936.

R. Veitchianum was introduced by Messrs. Veitch of Exeter from Moulmein, and was first exhibited by them in May, 1857. The leaves of this are almost glabrous, but covered—especially on the under surface—with small brown scales. The flowers are white, 3 to 4 inches across, and the edges of the petals are very finely crisped. This species comes near *formosum*, and is considered by some botanists to be only a form of that species.

Many hybrids have been raised from these species; and several of them show slight difference one from the other. The prevailing features are large open flowers in small trusses, white, with sometimes green, yellow, or rose markings in or outside the tube, and all very fragrant. Possibly the best of all is *R. Fosterianum*. This is a hybrid between *Edgeworthi* and *Veitchianum*, and is a worthy offspring of two such beautiful parents. The foliage is intermediate between the two. The flowers take more after those of *Edgeworthi*, but are produced with greater freedom, and show themselves off better. They are borne in loose trusses of from three to five, are very fragrant, white, with light yellow marks on one side of the throat, and often 5 inches across. When fully expanded, the flowers from a distance remind one strongly of a large Lily. Other good varieties are Lady Skelmersdale, Lady Alice Fitzwilliam, La Belle, Countess of Sefton, Countess of Derby, and a host of others.

Before closing mention should be made of *R. Countess of Haddington*. This is a hybrid between *R. Dalhousiae* and *R. formosum*. It has the long tubular flowers of the first named species, but instead of being yellow they are bright rose, and, like the other parent, sweetly scented. It is a good grower, flowers with great freedom, and is without doubt one of the most useful of the group. As these plants can be grown with ease, and only require sufficient protection to keep away frost, they might with advantage be used on a large scale, either as pot or border flowers, the beauty of their fragrant flowers fitting them well for decorative purposes.—W. D.

SOME SWISS FLORA.

To the botanist the mountains around the lake of Lemana or Geneva and up the Rhone Valley offer a fine field for research, and one rarely excelled in variety. From February to June there is a ceaseless supply of wild flowers in their season if one seeks for them in their proper habitat. The Crocus, mauve, white, and particoloured, is very early in its appearance. Indeed, directly the snow melts off the lower plateaux this charming little flower is seen on all the hill slopes for several thousand feet. They last well on till the end of April, and in the autumn spread forth a second supply. The Cowslip, Primrose, and Oxlip come next, and are in full swing by the middle of March, when also the Anemones begin. At this time the Violets, lavender, white and deep blue, the latter very richly scented, are broadcast in many parts, chiefly where there is some wooded growth about.

In March, too, the lovely little delicately scented Grape Hyacinth abounds in the bare ground of the vineyards and on grass slopes not too far up the mountains, and towards the end of the month the perfect blue Gentian, rather high up. Both the small and the large kind are found in their special haunts. Late in March or early in April the stately Daffodils, in the few places they favour, glorify their quarters with their wondrous wealth of gold. By the end of April and May the climax is reached when in parts whole patches of Lilies of the Valley, Orchids, Ranunculus, and Narcissus raise their elegant and perfumed heads. The last named around Les Avants are literally mown down by the peasants, in such quantity do they grow. I make no mention of the immortal Edelweiss and other flowers, rare or difficult of access, all the foregoing being of general growth and within easy reach of anybody of ordinary walking powers. There is a peculiar charm in these alpine flowers.

In the first days of April I went up to Noville, an Alpine village a few thousand feet up a narrow valley, the furthest side of the lake, and found many beautiful specimens already named; and up a gorge off the Rhone Valley on the outskirts of the Dent du Midi, on the Chamonix route, a small party of us revelled in the delights of carpets of Hepatica, blue, and also the rarer white, perfect masses of the sweet-scented Violet, the yellow Marsh-mallow, clusters of small pink Primulas, Crocuses, the close growing golden Rock Rose, Pansies, and another very beautiful flower, the name of which I know not, some white, and others mauve or striped. I have rarely spent such a delightful half dozen hours as in this alpine climb among the flowers, protected from the sun of a cloudless sky by the sweet Pine-clad slopes, and with an appreciative and intelligent English lady, whose love for flowers was also very great. For my part I presented my share of the Hepaticas and sweet-scented Violets to *vis-à-vis* at table d'hôte.

An excursion up another "shoot" of the Rhone Valley towards Châtaign D'Oex revealed some kinds we had not found before, and included Periwinkle, pink Hepatica, yellow Anemone (found in but few places, I believe), Snowflakes, masses of Gentian, shrubs of purple Daphne, and a flower something like the Star of Bethlehem, but yellow, several blossoms growing on same stalk. The latter we found in a marshy spot about 3000 feet, growing among the Snowflakes, which were almost over.

In closing, a word on the fruit trees round about this part may not be out of place. Both in the small garden plots in Montreux and in the orchards in the rich alluvial soil of the Rhone Valley, I was much struck with the profusion of blossom. It was quite an exception to see a tree of any kind, whether Cherry, Pear, Apple, Plum, or Apricot, without masses of blossom on every part. Whether the promised crop sets and comes to maturity or not I cannot say, but the signs of fruitfulness are most remarkable. I noticed both in the valley and pretty high up the extensive cultivation of the Walnut, and last, though not a fruit tree, an occasional Magnolia; now and then a really massive tree made a beautiful appearance to the eye.—J. A. CARNEGIE-CHEALES.

— THE REIGN OF THE CARNATION.—Dame Fashion is a fickle mistress, and under her sway the popularity of flowers rises and falls. Just now the Carnation occupies a lofty pedestal both in this country and across the Atlantic. A few years ago the devotion of whole houses to Carnations was a thing unknown, and the variety among these flowers extended no further than to the few grown in the beds. A new order of things has sprung into existence, and apart from the popular Malmaison section, the perpetual flowering varieties are much in demand. In many large establishments now Carnations are a speciality, houses are devoted to them, and blooms are obtained practically all the year round, while in smaller and less pretentious places you find that something else has been done away with to make room for more Carnations. All this has had the effect of bringing forth the best efforts of raisers, and a really up-to-date collection of Carnations in pots is a most interesting sight. Though the Carnation is accommodating, the plant is exacting. Given the treatment it requires nothing can be more satisfactory; withhold it, and the result is disappointing. Allowing all this the flower has a firm hold on public taste, and as far as one can see it is a hold that will last.—G.

BRODIAEAS.

THESE are, indeed, very showy plants, especially the Vegetable Fire-cracker, which, I believe, is the Yankee name for coccinea. This species is so distinct from all other flowers that when once known it is not easily forgotten. Brodiaeas, although closely resembling various species of Allium and Tritelia, nevertheless have a distinctness which renders them very desirable. They are easily cultivated either in pots or in the border. A few of them increase abundantly in their favourite spots, and they are extremely pretty in masses. Coccinea is perhaps the tenderest of all, but it will stand outside all the year if the position it occupies is well drained and facing south or west. The precaution, of course, can be taken of lifting the bulbs and potting them, so that they can be put in a place of security for the winter. It richly deserves such a small amount of attention.

Most of the other species to be mentioned require little attention if planted in moderately rich light soil; in fact, every lover of hardy flowers should have a special border prepared for the reception of choice hardy bulbs. In preparing such a border it is necessary to insure drainage and a good depth of soil, which of course can be qualified to suit the several and variable requirements of any particular set of plants. The Brodiaeas are all natives of North America, confined for the most part to the Western States. *B. coccinea*, represented by fig. 87, is a handsome species. The flowers are fourteen to sixteen in number, tubular, the tube from 1 to 1½ inch long, about half an inch through, of a deep reddish crimson colour. The scape is from 1 to 3 feet high. It is a most distinct and handsome species, flowering very freely and well adapted for pot culture or for a small border. It is not quite so hardy as most of the other species, but if the bulbs are planted deeply and the surface of the soil slightly covered during the winter it will be safe. *Grandiflora* has very narrow leaves, nearly round. The flower scape is from 5 to 12 inches high. The tube is of a purplish-blue colour. It is a very handsome, free-growing, and hardy species, flowering in July and August. I should add that coccinea blooms in the open from June to August.—T. R.

VENTILATION.

To know how and when to ventilate can only be mastered by carefully observing its effects upon different plants, together with a thorough knowledge of the constitutions and requirements of the plants being treated. The quantity of air we can give a house of plants will also very much depend upon how we begin with them, and the time of year they are started into growth. A number of Melons, for instance, planted in January must of necessity make their growth with very little ventilation, and that helps to render their leaves thin and fragile, consequently they must be more carefully ventilated than those planted two months later, because, to begin with, the latter would have more light and air, which would result in a robust constitution, and hence be capable of enduring sudden changes of temperature with impunity.

There are very few operations more difficult to teach young men than that of ventilating, simply because they fail to realise its importance further than to prevent the rise or reduce the already too high temperature. Very much more than that, however, is included in "giving air," for the manner in which it is done often determines the difference between a healthy and a sickly house of plants, while it is certain we should hear of and see less mildew, red spider, aphides, and other insect pests if the ventilators were always rationally worked.

Like many other gardening operations, it is impossible to give detailed instructions for ventilating that can be strictly applied under all circumstances, hence only a few general principles can be pointed out, and some practical observations made upon them, while these will be useful in proportion as they are intelligently applied. Medical advisers tell us that it is not when becoming hot, but when cooling, that the system is the most susceptible to chills, so that after getting hot we should try to reach the normal temperature gradually and uniformly, hence we ought to avoid draughts. Now, experience proves that these remarks are to a large extent as applicable to plants as animals, so that we do not think of taking plants directly from hothouses to the open air, but we prepare them for the change by "hardening them."

The fact that many plants can be grown so well without ever opening the ventilators proves that high temperature does not injure them, and the grower should bear this in mind when he has neglected to open the ventilators, and the temperature has run up to 20° or 30° too high; he should remember that the evils which follow will very much depend upon how he manages the ventilators, and nothing should induce him to let in a large volume of cold air. Far more care is needed in ventilating when the temperature has been allowed to rise too high than when ventilated at the proper time, because the air that would be comparatively warm, or just cold enough to be invigorating in the latter case, would be chilly, and often productive of baneful results in the former.

The aim should be, under such circumstances, to reach the normal temperature as imperceptibly as possible by opening the ventilators

gradually. Not more than a quarter of an inch must be allowed at first, and this should only be at the top of the house, unless the bottom ventilators allow the air to circulate round the hot-water pipes before coming in contact with the plants. Even then the top and bottom ventilators should not be open at the same time until after the proper temperature be reached, for that would create a draught, which is always injurious, more especially to over-heated plants; indeed, according to my experience the bottom ventilators are better kept closed, except in houses where plants have finished their growth, or on very warm still days. They are certainly better closed in the early part of the year if we wish to be free of red spider.

But the rational use of ventilators is not to reduce but to prevent the rise of temperature beyond a certain point, so that on favourable days a little air should be admitted as soon as the temperature begins rising, and it ought to be gradually increased as required. Sudden checks must be avoided in fruit and plant culture, for nothing is more productive of insect pest and disease. We want, if possible, to supply our houses with fresh air without creating a draught, and without unduly lowering the

FIG. 87.—BRODIAEA COCCINEA.

temperature, but this can only be effected with the ordinary arrangements by the exercise of care and forethought. It may seem superfluous to say that more air will pass through an inch space when the wind is rough than would pass through a foot when it was still. The direction of the wind should always be noted, especially when it is rough, and if possible ventilate from the opposite side.

There are days, however, when it is better to allow the temperature to rise considerably than to open the ventilators. There is nothing more trying for forcing than hot sunshine with a high scathing wind, or alternate hot sunshine with sudden cold storms, and that especially after a period of dull weather. On such days I prefer keeping the fires low and the ventilators nearly closed, with plenty of moisture, and for tender plants shade. This I find much better than opening the ventilators during such trying weather, which require very great care and constant attention, or, to say the least, an attack of red spider would be the result. Low span-roof houses are best ventilated through iron grates fixed into the wall a little above the ground line, and just under the hot-water pipes, and if more air be wanted open the doors at one or both ends as required. Plants very much object to a stream of air flowing directly on them; it often has the effect of drying and stunting them, and this cannot be avoided if top ventilators be used in low houses, hence the advantage of grates and opening the doors. Top ventilators, however, should always be provided, as they are useful during hot still weather.—PRACTICE.

RATES FOR GARDEN PRODUCE.—We observe that the South-Eastern and Chatham and Dover Railway Companies have decided to adopt the system of conveying farm and market produce at low rates between various stations, the conditions to be enforced being—that the produce shall be packed in the boxes on sale at the different stations, or similar ones; that the boxes shall be secured by nails, and not by rope or cord; that the produce shall be conveyed at owner's risk, and the carriage prepaid, the prepayment being made by parcels stamps on sale at the stations; and that no box shall be of greater weight than 60 lbs. If these conditions are fulfilled, the produce will be conveyed at 4 l. for every 20 lbs. and 1 d. additional for every 5 lbs., or part thereof, up to 60 lbs. (including delivery within the usual limits), from all stations (except those within twenty miles of Charing Cross) to Birchington, Broadstairs, Deal and Walmer, Dover, Folkestone, Hastings and St. Leonards, Herne Bay, Hythe, Littlestone, Margate, Ramsgate, Sandgate, Westgate-on-Sea, and Whitstable, and also from all South-Eastern and Chatham and Dover stations to London and stations in the companies' suburban district. The boxes are to be sold at the stations at prices ranging from 1½ d. to 5 d.

SOME LITTLE KNOWN COMESTIBLE PLANTS.

Le Potager d'un curieux Histoire, Culture et Usages de 250 Plantes comestibles, peu connues ou inconnues Par MM. A. PALLIEUX ET D. BOIS.

THE third edition of this work, describing little known edible plants of foreign countries, entirely re-written, with eighty-two figures, has just appeared; so it has been thought that a selection from the plants described might not be uninteresting to the readers of this Journal; for the authors, by means of an enormous correspondence with official and other persons in all parts of the world, have collected a vast array of interesting facts. The plants are, unfortunately, arranged alphabetically, so that if one wish to take all those mentioned of any particular natural order together, it involves the picking out the different genera separately from the index. Following the order in which they stand in the book, we come to:

Aponogeton.—*A. distachyum* (Thunb.), a native of the Cape, is quite hardy in this country. It has a remarkable rhizome, covered with globular tubercles. Mueller describes it as being naturalised in Australia, the tubercles being edible there, while the flower-stalks supply a substitute for Spinach. The authors think the tubers, though fine and white, are too compact, and carry a disagreeable taste of the mud in which they lie. They might be used for the starch which they contain. *A. monostachyum* (L.), and other species afford a food much enjoyed by the natives of India.

Bambusa.—The young shoots of several species of Bamboo are eaten in Japan, including *B. Metake*. They are cooked like Asparagus or pickled. The Chinese dry them and export them largely to Manchuria and Mongolia. Then, after being soaked in hot water, they regain their former size.

Lappa.—The "Bardane du Japon" is a variety of our own Burdock, *Arcetium Lappa* (L.). This is said to be eaten in Scotland, both leaves and young shoots. It is called Gobô in Japan, and is generally cultivated. The figure given shows long Radish-like, simple and branched roots.

Tropaeolum.—*T. tuberosum* has pyriform tubercles resembling a moderately sized Pear. They are used for food in S. America, but Europeans fail to appreciate them in consequence of their being acrid and having an unpleasant odour. It is said that they should be frozen and then cooked, when they become palatable.

Claytonia.—*C. perfoliata* (Willd.), a native of N.W. America, is spreading and becoming naturalised in many places of England. It is an annual, with connate funnel-shaped leaves. It is described as a useful plant in lieu of Spinach, or as a refreshing salad.

Cucumis.—*C. sativus* var. *sikkimensis* (Hook, fil.). The Sikkim Cucumber is cultivated in all India, but especially in Sikkim. The fruit is ovoid like a Melon or Vegetable Marrow, and has five placentas instead of the usual number, three. It is yellowish-white and red in colour, and might prove to be a valuable addition.*

Stachys.—*S. affinis* (Bunge). The so-called "Chinese Artichoke" has a long account. It is cultivated in several provinces of China, but is rarely so in Japan. It is now much grown in France. It cannot, however, approach the Potato, the reason probably being that instead of starch, this is to a large extent represented by galactane, of a character intermediate between starch and sugar. This, however, renders it more assimilable than starch. It is suggested that our own species *S. palustris*, of which *S. affinis* may be only a variety, might be cultivated, but it has longer rhizomes, which would require some amelioration, as they are bitter.

Raphanus.—*R. sativus* (L.) var. "Daikon" of Japan. Of this Radish there are several forms, of which three are figured, one being Pear-shaped, and another like a Cucumber. The figure is $1\frac{1}{2}$ inch in length and 1 in breadth, while the latter is $3\frac{1}{2}$ inches in length. These, however, are one quarter the natural size.

Foeniculum.—*F. dulce* (C. Bauh). The Sweet Fennel of Italy is believed to have been introduced there from the Azores. Earthed up, the broad bases of the leaves become white and tender. One disadvantage is that the seed degenerates, and must be secured fresh from Italy every year.

Petasites.—*P. japonicus* (F. Schmidt), is a representative of our Butter-bur. It is much eaten by the Ainos of Japan. They use the petioles, roasted or boiled, also pickled and as conserves. The flower spikes, which come up before the leaves, like those of our species, and of its ally the Coltsfoot, are also eaten, but the taste is rather bitter, though the odour is pleasant. The authors, however, do not appear to be able to recommend them.

Mesembryanthemum.—*M. crystallinum* (L.). The Ice Plant is an old-fashioned garnishing plant, ornamental in consequence of its minute globular water-glands, which give it a cool glistening appearance. The tender shoots and leaves may be treated like Spinach, and have an agreeable flavour of their own.

Phaseolus.—This genus affords many useful species, besides our Kidney Beans, Scarlet Runner, &c. Thus *P. Tunkinensis* (Loureiro) is cultivated for its seeds in Cochin-China, but requires a higher temperature than France or England can supply. *P. Ricciardianus* (Tenore) is a yellow-flowered species of China, remarkable for its extreme fecundity, but is rather tasteless. *P. Mungo* (L.) has many varieties. It is of Asiatic origin, and generally cultivated in India, Japan and China, where it is made into a fine vermicelli. It has been grown in France since 1878, and ripens its fruit yearly.

Dioscorea.—Numerous species of this genus are cultivated, one of which is the well-known Yam. The genus is indigenous in China, where three species are cultivated, including the Yam, *D. Batatas*. *D. glabra* (Roxb.), is cultivated in India and much esteemed. Of course they all require a hotter climate than England.

Amorphophallus.—*A. Rivieri* (Durien). This Aroid has a tuberous root and a stem carrying three much-divided leaves. It is nearly 3 feet in height. It probably originated in the south province of Japan. The spadix is surrounded by a red spathe. Stolons arise from the eyes in the tubers, which swell at their extremities, just as Potatoes. It will bear fifteen tubers.

Erythronium.—*E. dens-canis*, the Dog-toothed Violet, is known to all lovers of spring flowers; the variety of which, *grandiflorum*, is, according to the authors, a native of the south of Western Siberia, where it is widely collected and the bulbs are eaten, as well as sent to the Court of St. Petersburg.

Lilium.—Several species afford edible bulbs in Siberia and Kamtschatka—e.g., *L. tenuifolium* (L.), *L. Kamtschaticum*, *L. spectabile* (Fisch). *L. auratum* (Lindl.), wild in Isles of Nippon and about Yokohama, affords useful edible bulbs. So also does *L. speciosum* (Thunb.). Other edible Lilies are *L. Thunbergianum* (Ræmer et Schultz), *L. tigrinum* (Gawler), &c.

Tulipa.—Numerous Tulips cover the Russian steppes. One species common by the Don, allied to *T. suaveolens*, is eagerly sought after as edible by the inhabitants, but they never eat the others. Aitchison says that the bulbs of *T. montana*, which covers the arid plains of Afghanistan, are also eaten, adding that, deprived of their outer skins, the bulbs are sold in Bombay as "Salep." This name, of course, really belongs to the tuberous roots of terrestrial Orchids.

Plectanthrus and *Coleus*, genera best known to us for their variegated foliage, have also edible species. Thus, *P. ternatus* (Sims) ("Bot. Mag.," t. 2460) is called "Matambala" in Madagascar, and furnishes edible tubercles, which yield ten to twenty for each one sown. *Coleus tuberosus* (Benth.), is cultivated in the Malay Archipelago and Ceylon. Other species of both these Labiates are elsewhere cultivated.

Lycopus.—*L. lucidus* (Turcz), allied to our own Gipsywort (*L. europæus*) has tuberous rhizomes, which are used by the Japanese.

Sinapis.—*S. juncea* (L.), var. *napiformis*, has short conical and swollen roots. These form an important article of food in China.

Nelumbium.—*N. speciosum* (Willd.), the Lotus of the ancients, is a native of S. Asia, introduced ages ago into Egypt, where it has since become extinct. Both the rhizome and the grains are eaten in Japan; the former is said to resemble in taste the Radish, Cardoon, and Celery combined, while the fruits taste like Nuts and Almonds.

Euryale.—The only species, *ferox*, of this genus, represents the Victoria Regia in India. Both rhizome and grains are used for starch.

Nuphar.—*N. advenum*, the N. American representative of our yellow Water-Lily, affords a rhizome which is collected by Indian women of Dakota, and eaten with wild birds, and also stored up for winter use.

Nymphaea.—The ancient Egyptians made bread of the seeds of *N. Lotus* of the Nile, the rhizome being still eaten as Potatoes.

Oxalis.—*O. crenata* (Jacq), affords the tubers of an orange colour called Oca. It was first imported into England from Lima, South America, in 1829. The leaves can replace Sorrel.

Brassica.—*B. chinensis* (L), the Chinese Cabbage, is much cultivated and highly esteemed; it grows like a Kale, refusing to form a head. It is of great use in dry seasons in Bourbon, since it resists drought more than any other similar culinary plant.

Lactuca, *L. sativa*, vars.—Lettuces from the Pamir. These would seem to be likely to prove useful additions to our stock. The principal stem grows slowly, in consequence of the numerous side shoots which surround it. These are taken off, and furnish an abundance of excellent salad.

Crocus.—*C. cancellatus* (Herb.). This is eaten in Persia, the corms of which are said to taste like Chestnuts.

Sagittaria.—Varieties of our Arrowhead, *S. sagittæfolia* (L.), are grown in China for the globular tubercles. They are odorous and aromatic, though possessing a bitter milky juice. This is dissipated when boiled.

Besides the preceding the authors describe numerous species of *Solanum* and *Physalis*, and a large number of genera of *Cucurbitaceæ*; but the plants mentioned are of those genera with which our readers would most likely be familiar.—GEORGE HENSLow.

* It is figured in "Bot. Mag.," January 1876, pl. 7206.

LIVERPOOL NOTES.

AMARYLLIS AT AIGBURTH.

It was my good fortune a short time ago to visit Messrs. R. P. Ker and Sons, Aigburth Nursery, Liverpool, and to inspect the collection of *Amaryllis*, for which the firm is famous.

Having watched their progress for several years, and the improvement in form, habit, and floriferousness, one would have thought it almost impossible to advance much further, but progress seemed to be written over all. If only one had to be mentioned to support my statement that would be quite sufficient, as the long sought for pure white is at last found—a very small bulb, throwing a spike which was without marking of any kind. Nor is this all, for numerous new shades are appearing, but they are at present unnamed. In striking contrast to the present day varieties was one of the old types in bloom from Bermuda, insignificant but sufficient, to show the care and attention paid to the crossing of the new varieties. Most of those in flower were bearing two spikes, with from two to eight flowers on each.

I noted a few varieties particularly choice in every way as regards habit, colour, and form of flower:—*Cassandra*, reddish scarlet, white star and bands; *Bacchus* and *Imperial*, rich deep crimson; *Monarch*, fiery scarlet with rose bands; *Magnificent*, deep crimson with salmon suffusion; *Scarlet King*; *Virgin Queen*, white striped deep crimson; *The Queen*, beautiful rounded form, almost pure white; *Pink Queen*, glowing deep pink, very handsome colour; *Melpomene*, light ground, heavily veined red; and *Saturn*, lighter ground with red veins on upper petals.

It is to the credit of Messrs. Ker & Sons that they should take in hand a flower that has such a hold in the Liverpool gardens, *aulicum*, *equestre*, *psittacinum*, *Reginæ*, and others having been brought over by the Liverpool merchants, and flowered in their gardens. Again, at Prescott, eight miles from Liverpool, the useful and the first recorded hybrid, *A. Johnsoni*, was raised by a clockmaker named Johnson; whilst at Hurst House, near Prescott, the late Miss Willis, a celebrated horticulturist, had a choice collection, as had also the late Rev. Thos. Staniforth of Storrs Hall.

In growing *Amaryllis* too many persons think that almost any culture will suit, but to bring about success the routine, although simple, must not be neglected. As the plants go out of flower the warmest part of a greenhouse should be chosen, and copious supplies of water given until August, when it may be withheld, and the bulbs allowed a period of rest. Early in October the pots should be laid on their sides under the stage. If wanted to bloom in December or January place in a temperature of 60° or 65°. For later flowering start about the middle of January, giving a temperature of 50° to 55°, watering carefully at first. If the bulbs require potting see to it just previous to starting them, using two-thirds of good loam with one-third of leaf mould and silver sand.

HONOUR TO A LIVERPOOL HORTICULTURIST.

It will be gratifying to the many friends of Mr. R. Wilson Ker to learn that he has been chosen to adjudicate at the exhibition now being held at St. Petersburg. In addition to the above honour, we Liverpool people appreciate his election on the Floral Committee of the Royal Horticultural Society. Nor is the journey to Russia to be one of pleasure entirely, for although there is something like 2000 miles to be traversed, the above gentleman and his brother, Mr. A. W. Ker, have taken with them seven specially constructed cases containing selections of the *Hippeastrums* referred to in the above notes.

NATIONAL AMATEUR GARDENERS' ASSOCIATION.

Last Thursday evening the Liverpool branch of the above Society held its monthly meeting, when some very good exhibits were brought by members, but more especially the Orchids by Mr. Drake, whose blooms of *Cattleya citrina* were awarded a special prize. Mrs. Drake won the prize for a gentleman's buttonhole, and Miss Hunter for *Auriculas*. Other prizewinners were Mrs. McGregor, and Messrs. Redfern and Gillanders. As usual the lecture for the evening commanded the attention of all present. The lecturer was Mr. J. Cliffe of Waterloo, who chose the subject "Budding and Grafting Roses." In a most business-like manner Mr. Cliffe described the processes of "budding and grafting," and strongly advocated the merits of the budded over the grafted Rose, which latter he advised should never be bought. He gave some very interesting information regarding Stocks. For a dry soil, and where it is necessary for the roots to go deeply in search of moisture, he recommended the seedling Briar, but for all purposes and all things considered, if one must choose, then he would take Roses budded on the Briar cutting. A vote of thanks concluded a pleasant meeting.

DOUBLE WALLFLOWERS.

Whatever objection may be urged against double Wallflowers, we cannot afford to ignore their claims at this season of the year. Two beds filled with dwarf bushy plants, carrying spikes some 12 to 15 inches in length, of all shades of brown, claret, purple, and hosts of intermediate shades, are now delighting us with their handsome appearance; the foliage, too, which is much more striking than in the single varieties, greatly enhances their appearance. For bedding purposes they are invaluable, and as the season for sowing is almost at hand I should recommend a packet to be purchased. When planting out give more space than for the single varieties. To get the best results from them they should be transplanted, and sufficient space given to allow of perfect development, and when planting-out time comes round, each plant can be lifted with fine roots, and receive no check. By adopting

this system there will scarcely be a feeble plant. Another detail is, when the winter is past the plants will have become somewhat loose about the stem. Fill in the spaces, making the ground firm, give a slight top-dressing of artificial manure, or water with liquid, when spikes of flower almost double the size will be the result of this small attention.

THE WEATHER AND THE FRUIT CROP.

Frosts of various degrees, but of sufficient intensity to blacken, and from reports from the Cheshire district, to destroy acres of early Potatoes and blacken *Rhododendrons* in flower, have been the order for the past few days, and it causes serious misgivings as regards the Pear, Cherry, and Plums, which have been in full flower for the past fortnight. It will be a great disappointment if we have a short crop again this season, as in many instances last year it was almost nil. Apples are not in full blossom, and so we hope that this, our most useful of fruit, will be spared the rude blasts of the cutting winds of early May. Currants, Gooseberries, Raspberries, and Strawberries are grand in appearance.—R. P. R.

PINCHING FRUIT TREES.

I THINK pinching to a certain extent assists in fruit bud formation, provided, as Mr. Luckhurst says, the work be done rightly and at the proper time. I venture to say that trees from which barrowfuls of shoots have been cut each season for years, and still produce few or no fruit buds could—in the course of, say, two years—be made very fruitful by pinching, in conjunction with other processes for preventing an excess of sap forcing its way into a thicket of gross shoots. By checking this excess of sap through having the roots under proper control, I can then pinch, and prevent an excess of barren shoots, in faith of helping to form fruit buds.—H. MITCHELL, *Druidstone*.

As far as I can glean from the various opinions already expressed, there are not many gardeners in favour of summer pinching. I trust pinching will not be confounded with summer pruning, or perhaps the discussion may prove a hindrance instead of a help to those who are hoping to profit by it.

I have been experimenting for some few years, and at one time I thought I could bring young trees into fruiting earlier by continuous pinching. The idea was to prevent strong roots by preventing strong growths, and thus get fruit buds on the current year's growth. I succeeded with some varieties, but not others, and not sufficient with any to pay for the extra labour. I took the points of the shoots out when they had made five full sized leaves, and the sixth was half developed. All other shoots were stopped to one leaf as soon as that leaf was formed. Shoots would grow out from three, and sometimes four of the leaves, and a fruit bud would sometimes form at the next leaf below the lowest shoot. These remarks apply more particularly to Apples.

Summer pruning I consider essential to all fruit trees which are winter pruned. In Apples and Pears I consider the best time is when the points of the shoots show signs of growth ceasing. Pears about the end of June, Apples about the end of July. But they differ according to season, soil, and variety. Summer pruning causes fruit buds to form on the previous year's growth, that is, the dormant buds below the shoot or shoots which have been pruned back, also on the old spurs which would have been smothered and too weak if summer pruning had not been done.—J. L.

[We are inclined to think that enough has been said at present on the general question of pinching, which has been confounded in some instances with summer pruning, and would now ask our able practitioners and others to consider a few definite questions, and under the heading of "BLOSSOM BUD FORMATION" explain in separate paragraphs—

1. What is a blossom bud?
2. How it is formed?
3. What helps, and what hinders, its production?
4. If, and in what way, a blossom bud can be changed into a growth bud?

Some of our friends occasionally say they would like to contribute more frequently but feel at a loss for a subject. They have one now; and with those questions correctly answered, we suspect the philosophy of pruning will be better understood. In the meantime we thank all our correspondents (some of whom have still more to say) for the many useful hints they have given in the several communications.]

BLACKTHORN WINTER.—It does seem as if this touch of wintry weather, which comes in with the blooming of the Blackthorn, or thereabouts, never can be evaded. Certainly southwards the touch of cold keen easterly winds, with sharp white if dry frosts at night, came this year a little later than usual, and Plum bloom was largely over, but it caught the Cherry and Pear bloom in its greatest profusion. If the fertile organs of this have escaped harm all the same, certainly it will be wonderful. There is not only a great bloom, but there is far too much. If frost has killed one-half of it there will be plenty left, but then it is the bloom which might have set best and produced the finest fruits, that possibly may have been killed. We shall soon be hearing from many directions, as to the effects on the fruit bloom of the latest touch of Blackthorn winter.—OBSERVER.

THE YOUNG GARDENERS' DOMAIN.

THE SHRUBBERY BORDER.

NEARLY every establishment has one or more borders devoted to ornamental trees and flowering shrubs, but how often are these left year after year to take care of themselves, with the inevitable result that they rob each other of their natural beauty. Few borders are more charming when well kept, and if the ground were well trenched and manured, and burnt garden refuse incorporated, before the trees were planted, none would look more beautiful. Newly formed borders, where the trees have vacant spaces between, may be planted with annuals; but these should not be sown or planted thickly. Poppies form a main feature in some gardens, but even a Poppy thrives better with "elbow room;" and therefore should not be crowded, so that one plant produces only one bloom, as is often the case. There are many annuals which can be suitably employed, and give a grand effect if judiciously planted, not forgetting the fragrant *Nicotiana affinis* for an evening display.

Provided the spaces at command are large enough, Dahlias, Delphiniums, Hollyhocks, Foxgloves, Campanula pyramidalis, and Helianthus in variety will add to the general effect. Then, again, bulbs in many varieties, to give an early and late spring display, cannot be omitted, for what gladdens the heart more than these useful and pretty flowers, which tell that spring has come again? For many years after planting, the borders can be kept quite gay from February to November. The annuals, if sown in autumn, will provide a much earlier summer display than when they are sown in early April. But in no case should a mass of self-sown plants be tolerated, or the shrubs will suffer. It will be much the better plan to lightly fork over the vacant spaces between shrubs, and sow the seed in ringlets 1 foot in diameter, both in the autumn and spring months.—FOREMAN X.

DAHLIAS.

WHERE Dahlias are largely grown there are few plants that make a better display, and they are always useful for cut flowers and decorative purposes, especially the singles and Cactus varieties. The object with Dahlias is to obtain large, strong, hardy plants by the time it is safe for planting outside, but of course no hard and fast rule can be made for this operation.

The old tubers that were lifted and stored in the autumn should be carefully examined and placed in a temperature of 60° to 65° at night, 65° to 70° by day, about the middle of January, covering them with cocoanut fibre refuse and giving an occasional damping until they have made a start. When the tubers have made growths about an inch in length some of them may be taken with a little of the tuber attached, and be potted in thumbs if an increase of stock is desired. Do not let the growths get too far advanced before dividing the old tubers; two shoots on each division will be sufficient. Pot them in small or large 48's, according to their size, using a compost of two parts of loam, one of leaf soil and sweet horse droppings, with sufficient sand to keep it porous, affording a temperature of 65° at night. It will be found necessary to lightly damp occasionally and shade the plants when the weather is bright until they have made a good start.

After the plants have produced a fair amount of root they should be removed to a cooler house, 55° at night will be suitable, and a neat stake must be placed to each. It is necessary at this stage to look over them twice daily when the weather is bright, as there must be no lack of moisture, and a little weak liquid manure given occasionally will be advantageous. As time goes on and the sun gains power the plants must go to cooler quarters, but they should be covered at night for some time. Give air on all favourable occasions, and as soon as they can stand being fully exposed remove the lights, but keep them in readiness in case of rough weather.

When the time has arrived for the final planting the large varieties should be placed at a distance of 5 feet, and dwarfier sorts about 4 feet apart, thus giving ample room between them for the necessary work during the summer. Dahlias are gross feeding plants, so in planting it is a good plan to take out a large hole and place a supply of manure in the bottom, covering this with soil before the plants are put in. Make the soil fairly firm by treading around them, and place a stout stake to each. If the weather is hot and dry at the time of planting, or at any time during the summer, they should be supplied with water, and occasionally with liquid manure after they have made a good start. Attend to the tying as it is required: do not let the plants become thick in the centre, for they always thrive better if the air can pass freely between the growths.

When the autumn arrives and the plants are cut with the frost the tops should be removed to within 9 inches from the ground, and the tubers remain for a few weeks with a little coal ashes thrown over them to be thoroughly ripened. The lifting and storing of the tubers must be carefully done, so that none of them gets injured in any way, for if bruised they will be of little use for another season.—P. R.

NEW RÔLE OF THE GERMAN EMPEROR.—The Kaiser is a man of many parts, and according to a weekly contemporary, his latest hobby is landscape gardening. Under his instructions a transformation of the famous Thiergarten in Berlin is taking place. Trees in some parts are being cleared away, making open stretches, and in other places timber trees are being planted in groups in accordance with the idea of the versatile Emperor. It is a compliment to the landscape gardeners of this country, for, as the authority states, he intends to give the place more of the pleasant character of an English park.

FRUIT FORCING.

Cherry House.—The Cherries are ripening rapidly, and they must be kept dry, but moderate air moisture should be maintained by damping the floor with the syringe, air being admitted constantly, or condensation will seriously affect the fruit. The border must also be examined, not being deceived by the surface, supplying water to keep the soil moist down to the drainage. Tie in the shoots as they advance, and stop those required to form spurs at about the fifth leaf. Black aphides must be kept under by dipping the shoots affected in tobacco water, gently rubbing them with the fingers, or their shining bodies will throw off the decoction. Ventilate freely on all favourable occasions, and when the external conditions are unfavourable recourse must be had to the heating apparatus to insure a circulation of air. Netting will be necessary over the ventilators to prevent birds attacking the Cherries. Trees in pots should be well supplied with water.

Cucumbers.—Plants that have been in bearing some time, and show signs of exhaustion, had better be removed and their places taken with healthy young plants. Assist any plants that show signs of weakness by removing the staminate blossoms and the first fruits, stopping at every third or fourth joint, removing all superfluous growths. Shading will be necessary for an hour or two in the middle of the day when the sun is hot, especially for houses facing south, but shade only to prevent flagging. Houses with the roof-lights facing east and west will not require shading, or only in the afternoon. Little or no fire heat will be required by day, shutting the valves about 8 A.M., and opening them again about 4 P.M. or later, keeping a good moisture by damping the floors.

In Pits and Frames.—Sow seeds to secure plants for placing in pits and frames, a fair amount of bottom heat being necessary, which is insured by using the less decomposed material from exhausted hotbeds, with about a fourth of fresh material; ventilate moderately if the weather is cold, and close as early in the afternoon as safe, running up to 90° or more, and employ night coverings. Attend to the linings with a view to maintain a good bottom heat, but avoid rank steam.

Peaches and Nectarines.—*Houses Started at the New Year.*—The varieties Alexander, Waterloo, and Early Louise Peaches, with Cardinal and Advance Nectarines, are now ripening, and must not be syringed; but Hale's Early, A Bee, Dr. Hogg, Dymond or Grosse Mignonne, Stirling Castle, Royal George, and Crimson Galande Peaches, with Early Rivers, Lord Napier, Humboldt, and Stanwick Elruge Nectarines are only about completed stoning, and must not be subjected to a higher temperature than 60° or 65° by artificial means, commencing to ventilate at 65°, and not allowing 75° to be exceeded without full ventilation. If the fruits are too thick, remove the smallest, apportioning the crop to the vigour of the trees. Draw the leaves aside, or even them, so as to expose the fruit to light, raising such as require it on thin laths placed across the trellis wires with their apexes to the sun. Maintain a good moisture in the house, but never a stagnant atmosphere. Water the inside border copiously, and mulch the surface with about an inch thickness of short, rather lumpy manure. If the fruit is required ripe as soon as possible, maintain a night temperature of 65°, 70°, to 75° by day, with 80° to 85° or 90° from sun heat, but it is better for the trees to continue 60° to 65° as the night temperature, 65° artificially by day in dull weather, 70° to 75° with sun heat, closing at the latter.

Houses Started in February.—The fruit being in the early stages of stoning, should be reduced to two on strong shoots and one on the weaker, not leaving too many, for there is danger of their not stoning in that case, while they will be small if they should stone. Retain in all cases the fruit best situated for receiving air and light. Thin the shoots where crowded, pinching laterals to one leaf, and secure the growths to the trellis as they advance. Syringe the trees twice a day in bright weather, but only once in dull, and not then if the foliage does not become dry before nightfall, or it will be found dripping with moisture in the morning. The temperature by artificial means may be kept at 55° to 60° at night, and 60° to 65° by day, ventilating from 65°, and fully between 70° and 75°. Supply water to the roots as required, affording weakly trees, and those carrying heavy crops, top-dressings of fertilisers occasionally—say every fortnight or three weeks—washing them in moderately, or afford liquid manure alternated with the waterings.

Trees Started in March.—Thin the fruit now that it is swelling freely, and choice can be made of the most promising for the crop. Reserve those on the upper side or front of the trellis; two or three on strong shoots will be ample to leave, and proportionately fewer on weakly growths. Remove all superfluous shoots gradually, retaining those only for attracting the sap to the fruit, which stop at two or three joints, and those from the base of the present bearing wood for furnishing fruit another season, with such extensions as are necessary. Train the growths as they advance, securing them loosely to the trellis. Afford liquid manure to such as require more vigour, but avoid stimulating vigorous trees too much, as that will encourage wood at the expense of the fruit stoning. Keep red spider under by syringing, and if aphides or other pests appear promptly apply an insecticide.

Late Houses.—The fruits have set well, and should be thinned as soon as the best can be decided upon by their taking the lead in swelling. Remove the smallest and worst-placed first, leaving a few more only than will be required for the crops, but regard must be had to the vigour of the trees, and their liability to cast some of the fruit or otherwise in stoning. Disbudding and laying-in the shoots should be carefully attended to, doing the first gradually, and the latter with due regard to the swelling of the shoots. A temperature of 50° at night and 55° by day artificially will be sufficient to keep the trees in steady progress; ventilate freely above that, unless it is desirable to hasten the crop, when a temperature of 55° at night and 60° to 66° by day may be secured, with 70° to 75° from sun heat, ventilating from 65°. Syringe the trees in the morning and on fine afternoons.

Unheated Houses.—Despite the frosts the trees have set quite four times more fruit than they can possibly bring to maturity. Commence thinning them when the size of Horse Beans. Over-burdening the trees in the early stages of the fruit swelling prevents their making wood for another season's crop, while excessive disbudding may cause the fruit to fall or a strong growth to be made. A moderate syringing on fine mornings will be a great assistance in ridding the trees of the remains of the blossoms, but afternoon syringings are not advisable. Ventilate at 50°, not allowing an advance above 65° without full ventilation, and close at 50°, or before if there is a prospect of frost at night.

Pines.—Plants with fruit in an advanced condition require a moderately high and moist atmosphere, but ventilation must be carefully attended to. Admit air at the top of the house at 80°, and maintain the temperature during the day at 80° to 90°, closing at 85°, but unless desired to enlarge the crowns do not quite close the house. Maintain 70° at night and 75° by day, and a steady bottom heat of 80° to 85°. Supply water as often as required, on every occasion employing some stimulant of an all-round nature, such as guano, 1 lb. to 20 gallons of water. Syringe the house and plants two or three times a week, according to the weather, and otherwise maintain a genial condition of the atmosphere for the proper development of the fruit.

HARDY FRUIT GARDEN.

Apricots, Peaches, and Nectarines.—The reduction of wood growths must continue until all unsuitable shoots are dispensed with. Foreright growths cannot readily be fastened in, so should either be cut out entirely or shortened to form spurs. Artificial spurs may be freely encouraged in the case of Apricots, but less so, if at all, with Peaches and Nectarines. Suitable young wood may usually be found to furnish the requisite amount of bearing shoots for the succeeding season, and the chief matter rests in the proper selection of the best placed, retaining only an adequate number for furnishing the space after the present season's bearing shoots are cut out in autumn.

Watering Fruit Trees.—In light, dry porous soils, trees, especially those growing on walls, will require water at the roots to sustain growth, support fruit, and prevent attacks of insects. Old fruit trees are benefited by copious supplies of liquid manure, which will add nutriment to the soil upon which the roots can draw to assist in the development of the crop. Weakly growth in various trees is often the result of poverty of food and moisture. Much good follows from an application of water, but better results are attained when stimulants are applied of a sustaining and nutritive character. Newly planted trees and bushes must have the soil maintained moist about the roots, so that the fibres may extend unchecked in a healthy medium.

Syringing Fruit Trees.—The syringe or garden engine is a valuable instrument in the work of maintaining trees healthy and clean. On walls the attacks of insect pests may be largely neutralised by vigorous cleanings of water well directed against the branches and foliage. The force of the application dislodges the pests, which are prevented gaining a foothold by repeating the operation. Trees and bushes newly planted often break more evenly into growth when the buds are moistened, especially if the weather should be dry and warm.

Mulching Fruit Trees.—The best season for affording a liberal mulch to the majority of fruit trees and bushes is during the present month. After a copious watering, it is not desirable that the moisture should evaporate quickly. This may be prevented if a mulching of manure is applied. For young newly planted trees or bushes against walls, or in the open, the material ought to be of a light, littery character, and not thoroughly decomposed. In the case of well-established trees, short manure is better, as it lies closer, thus retaining moisture more readily. Raspberries, Currants, and Gooseberries soon appropriate the virtues of a generous mulch, and are largely kept in vigour and fruitfulness by frequent renewals. To be effective, mulching must cover the whole area of ground occupied by the roots; this in the case of bush and standard trees extending as far as the branches.

Strawberries.—A liberal layer of equal parts of long and short manure ought to be placed between the rows of established fruit-bearing plants without further delay. The short manure is useful for feeding the roots and conserving moisture in the soil, while the longer material washed by the rain and bleached by the sun forms an admirable resting base for the ripe fruit when that is plentiful.

Moisture must not be withheld from Strawberries where the land is of a porous character. The value of a good mulch is very apparent in such soils. The manure assists in retaining the moisture, and acts as a medium for distributing the water applied evenly and regularly. There is no better way of applying water than over the mulching, and a copious supply of liquid manure may also with advantage be given to plants when the fruit is set.

Training Young Fruit Trees.—The habit of the future tree depends largely on the attention given to training when young. The shape of the tree having been decided upon, it is important that the growths be regulated and trained in the desired direction. Superfluous shoots must be entirely removed. Disbudding may be practised when the growths are not too long, but if extended too far, the best plan is to remove them with a sharp knife. Young trees of Apricots, Peaches, and Nectarines may be allowed to grow freely, merely thinning-out and regulating growths, so as to produce as far as possible an even development. Where there is any difficulty in effecting this, the strong shoots growing very vigorously, they ought to be depressed, and those weaker raised to a more upright position. Weak growths may be thinned from the base of Raspberry stools, suckers removed from Currants, and gross-growing wood taken from any fruit tree producing such.

Destroying Insects.—Aphides are likely to attack wall trees, especially Cherries and Plums. The points of shoots are a favourite place of infestation. The best way of cleansing them is to dip in some insecticide, and afterwards vigorously syringe the affected parts. Where the insects are less numerous dustings of tobacco powder will destroy them, and much benefit will be derived by the trees if syringed with quassia extract, and frequently with clear water. These applications also help to keep down red spider.

THE BEE-KEEPER.

SPREADING BROOD.

NOTHING must be left to chance if bee-keepers are to derive full benefit from their bees when the honey flow comes. All will depend on the treatment they receive during the next two months whether the various colonies in the apiary will be in a satisfactory condition when that time arrives. There are many devices practised by bee-keepers to assist the bees to increase at a rapid rate. Amongst them is spreading the brood. This operation requires some skill in manipulating the combs and brood, otherwise it will have the contrary effect. The plan usually adopted is to place an empty comb, or a full sheet of foundation, in the centre of the brood nest as soon as the comb is filled with brood. Another empty comb is placed in the same position. This being repeated as often as necessary.

If the weather is warm a strong colony will increase at a rapid rate if the spreading of the brood is not overdone; but should a sudden change in the temperature take place, the bees will be unable to cover all the frames in sufficient numbers to keep the brood warm—that in the outer combs will thus become chilled, and the stock will then be in a more backward condition than if the bees had been left alone. For this reason we do not recommend the spreading of brood, as usually understood, but prefer the safer plan of providing fully drawn out clean combs as often as necessary. Instead of placing them in the centre of the brood nest they are put on the outside, next to the comb that is filled with eggs and brood. The stock is examined about every fourth day, and if the comb next to the outer one is filled with sealed stores it should be uncapped. The bees will thus have plenty of natural stores close to the brood, and will increase at a rapid rate if properly covered. In a few days the opposite side of the brood nest may be operated on in like manner, and the result will be a strong colony of bees when the honey flow comes.

By working on the above lines there will be no danger of chilled brood, as the queen will not lay more eggs than the bees can properly attend to. If the stock is short of sealed stores close the division board and feed with warm syrup, as advised in previous notes.

RENEWING COMBS.

It is necessary to constantly bear in mind the advantage of having a supply of clean combs on hand; and as spring and early summer is the season when the bees will draw out worker cells, preparations should be made so that a stock of comb foundation is on hand when required. Combs will not last for an indefinite period, as they become clogged with pollen and other refuse, and when in that condition should be removed and melted down or destroyed. It is a good plan to examine the stock of comb, whether in the hive or stored away, at least once a year, the spring for preference. The comb remaining will then be always in good condition.

If an undesirable comb is filled with brood it should be marked and removed at the end of the season. We once saw some combs that were filled with healthy brood removed from a frame hive in May and placed in the open air for the bees that were on the wing to clean out the stores. On examination the brood was found to be all dead, as they had been exposed a day or two, and thus a few thousands of valuable bees were destroyed. We need hardly say this was a case of mismanagement. Bees are too valuable to be destroyed in this manner during the spring.—AN ENGLISH BEE-KEEPER.

•• All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," 8, Rose Hill Road, Wandsworth, S.W., and NOT to 12, Mitre Court Chambers, Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *nom de plumes* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Lavender on Grass (Avis).—The Lavender would succeed on grass like any other low-growing shrub, only give them some good soil to grow in. The cuttings should not be inserted until September or October. Use young wood, place in free sandy soil under hand-lights, and plant out during the following spring. It is desirable to keep the ground round the stem free from grass, at least until the plants become well established.

Muscat Vine Breaking Unevenly (M. K.).—It is difficult to assign a reason for the buds breaking unevenly, but it generally arises from overcropping and consequent indifferent perfecting of the basal or pruning buds. We have found the best recuperative to be in encouraging more growth and not pruning so closely, growing the Vine on the semi-extension system. The Lady Downe's Vine should have the flowers carefully fertilised, taking pollen from the Hamburgs or other free-setting varieties. It would probably colour better by dressing the border with basic slag phosphate, or use a mixture of double sulphate of potash and magnesia, one part to three parts of bone superphosphate, using 4 ozs. of the mixture per square yard, and pointing in very lightly.

Destroying Black Fly in Peach House (Jardinère).—The most effective, but not always the safest, method of curing the Peach fly, *Aphis persicæ*, in a Peach house is fumigation with tobacco paper, or vaporisation with nicotine essence. The danger from the use of either is giving an overdose, when the foliage suffers serious injury, or may even fall. With judicious application and repeating on two or three consecutive evenings the pests are annihilated for the time being. We find it a better plan to go over the trees, and with the fingers dipped in tobacco water wet the affected parts thoroughly by gentle rubbing, and then fumigate the house, taking care to have the foliage dry and not give an overdose. Another good cure is to boil 4 ozs. of quassia chips in a gallon of soft water ten minutes, and dissolve in it, as it cools, 4 ozs. of softsoap. It should be stirred, and the trees syringed with it twice or thrice. The day following they should be syringed with pure water.

Freesias Outdoors (Idem).—We have no personal experience of these as outdoor plants, and hardly think they would succeed in a warm situation, as they flower during the winter, and are therefore likely to be cut off by frosts. We find they require a structure from which frost is excluded for their successful flowering. Freesias are largely and very successfully grown in Guernsey. See note on Freesias out of doors on page 383.

Chrysanthemum Leaves Blackened (F. W.).—The leaves are not, so far as we can discover, affected by rust fungus. The plants, however, are attacked by a worse enemy—namely, the so-called stem eelworm, *Tylenchus devastatrix*, which causes the leaves to become brown, black, clammy, and dead; even the plants sometimes succumb, turning black and dying off at the collar or root. We have used with advantage soluble phenyle, 1 fluid ounce to 6½ gallons of rain water, and dusted the plants with tobacco powder. The pests took their departure, as the tobacco unquestionably dissolved out on the injured and moist leaves, and sunk into the tissue. Another method is to use methylated spirit, spraying on and covering every part of the plant with the finest possible film. Pick off the worst infested leaves and burn them, then dust with either tobacco powder or black sulphur (*sulphur vivum*), and use air-slaked lime with a little kainit in the soil, or water with lime water made in the usual way, and alternate with kainit 1 oz. to a gallon of water, and follow with nitrate of soda quarter ounce to a gallon of water.

Silver Bicolor Pelargonium (C. T.).—The truss of the double flowers is good, and the leaves clear. The variety is worthy of preservation and increase for home decoration, but we should not like to say that either it or any new variety possesses material value without seeing plants. If you raised it from seed you are justified in giving it any name you desire that is not already given to a prior variety of the same type.

Cutting Back One-year-old Seedling Seakale Plants (Somerset).—The plants we presume are running to "seed" or showing flower heads. These should be cut away to the embryo buds, or the flowering stems be removed just below the leaves. The buds will then develop leaves, and by thinning to two or three on a plant, removing the weakest, good crowns will be secured. Of course, on weak plants only one, on moderately vigorous two, and on very strong plants three crowns or buds should be allowed to develop. The earlier the thinning is attended to the stronger the crowns will be. By cutting below the embryo buds some time must elapse for the root stem to form buds, and this throws the ripening back, hence the plants are not so good for early forcing, though they answer well for later use. The buds in this case also must be thinned.

Apple Tree Buds (A. Z.).—The microscope fails to show any insects in the buds, and we repeat, the birds take them as food, not for the insects or animal, but for the vegetable substance. Beyond the advice given last week, page 375, we cannot suggest anything to deter the depredations. We had an orchard and fruit plantation almost surrounded by woods and plantations, and for three years the bullfinches had all the fruit in the bud, but when we used the gun, in spite of gamekeepers and lovers of Nature, plenty of fruit followed. Birds are very delightful, and those who prefer them to fruit will protect them, but if fruit is of the first importance birds must often be either baffled or shot. Even if in your case the birds were destroying the buds for the sake of supposed insects in them, that would not make the case any better from a fruit point of view; but there were no insects in the buds.

A Sluggish Madresfield Court Vine (R. L.).—The growths are, as you say, "stunted," but very prolific, having a fairly promising bunch at the third, and another cluster for fruit at the fifth joint. Both the wood, leaves, and bunches are quite clean and healthy, but appear deficient in vigour. The comparison with Black Hamburgh is hardly doing justice to the Madresfield Court, as the first is one of the freest growing varieties, and the latter not by any means so free in starting into growth, though we have seen it quite vigorous under the same conditions. The root is not what it ought to be, for though the larger parts are healthy, the fibrils are dead, and hence the Vine is not supplied with sufficient sap to sustain the growth. Possibly the border has been kept too wet, or the roots may have come in contact with something unsuitable. The temperature should be 60° to 65° at night when the Vines are in leaf (not "just above 50°"), and 70° to 75° in the daytime (not "60°"), rising to 80° or 90° with sun (not "70° to 80°"). Those are the proper temperatures for free progress, though at night the temperature may fall 5°, and the same on dull days from the figures given. In addition to raising the temperature we should apply a dressing of bone superphosphate, dry and crumbling, three parts; nitrate of potash, crushed fine, two parts, and gypsum, ground, one part; mixed, using 4oz. per square yard, and pointing in lightly without disturbing the roots, or if these are near the surface, cover with a little decayed manure or turfy loam. Active fibres may then be produced by the sound parts. The dressing can be repeated after the Grapes are thinned and about a quarter swelled.

Diseased Cucumber Plants (J. W. T.).—The sturdy stemmed plant has fallen a prey to the smother fungus, *Sclerotinia sclerotiorum*, syn. *S. libertiana*, syn. *Peziza postuma*, which lives or grows on the cuticular cells and immediately underlying tissues. A yellowish discolouration first appears, and afterwards a felt like coat, quite white, and in this the sclerotia are produced in the form of small black bodies, and these carry over the disease from year to year, but the mycelium also may remain dormant, and grow again, similar to Mushroom spawn. To save plants after the attack has become pronounced is very difficult, but you may dress the plants well with freshly burned best chalk lime, ground, not slaked, to a powder, rubbing it on the stem above the soil where the yellowish and white marks appear; also sprinkle freely about the stem at the collar but not more than to make white, as the lime may burn the stem and roots. If the fungus has not "eaten" round the stem the plants will recover to some extent, but usually the lime does not reach the deep seated mycelial hyphæ, and it progresses in the living tissue, ultimately smothering and girdling the whole stem. It is, perhaps, the worst of all diseases that affect the Cucumber and some other plants. In your case it has come from the soil—a very sandy vegetable or peaty mould of a loose nature, and full of the roots of various natural vegetation, chiefly grasses. The fungus was found on one, and in another an eelworm, *Tylenchus devastatrix*. No eelworms were found, however, on the Cucumber plant roots or root-stem. We advise as a preventive the use of lime freely with the soil, and let it be best chalk lime, not magnesian, 2½ parts to 100 parts of the freshly cut turfy soil, and along with it use 1 part of kainit to 100 parts of the soil, which will give 103½ parts—pecks, bushels, barrowloads, or cartloads—and let the mixture be even in the stacking of the turfy soil. It should lie in the heap three months before use, then chop down from top to bottom perpendicularly and mix or turn over at least once, so as to get the top and bottom evenly incorporated. This is the best preventive of root affections with which we are acquainted, and one of the very best for the health of the plants. If the turf must be used relatively fresh, place it a foot deep and sprinkle on half a pound of freshly burned and slaked chalk lime, and 4 ozs. of kainit per square yard. Chop up, turn over well, let lie a few days, turn again, and then use in the course of a few days.

Red Spider on Violets in Frames (Worcester).—The best remedy is plenty of water at the roots and a moist genial atmosphere. Drought is the element in which the pest thrives. Syringe the plants with clear soot water made by placing a half peck in a bag and this in a tub with 30 gallons of water, stirring well once or twice daily for a week, then use the clear liquid only for syringing the plants. The Violet plants should be grown outdoors in the summer, and with proper attention in mulching and watering, they will not be affected with red spider when lifted and placed in the frames.

Tulips Diseased (Tulip).—The bulb partially decayed is affected by the Tulip mould fungus (*Penicillium glaucum*), which, though generally a saprophyte, sometimes develops a parasitic mode of life. It most commonly affects the Tulips that have been grown in the same place for a number of years. We have found that careful removal of all the old bulbs, on which it develops most rapidly, and whence it spreads to newly planted, even imported bulbs, very important. Of course a change of soil is desirable, but not often feasible, hence dress with quicklime, $\frac{1}{2}$ cwt. per rod, and apply during a dry time some few weeks in advance of planting, pointing-in lightly. It helps to destroy dead bulb scales and to kill the fungus. But give the land also a dressing of fertiliser, such as three parts of bone superphosphate and two parts of double sulphate of potash and magnesia mixed, using 4 ozs. per square yard. The other bulbs are "touched" with *Botrytis galanthina* and the *Penicillium*, and will develop more or less when they are placed in moist soil. Dress the bulbs with quicklime, or even Bordeaux mixture, before planting; but the thing is to disinfect the land and remove all diseased bulbs.

Pear Growths Diseased (J. S.).—Yes, the young growths are infested by two, and even three diseases. One is the Pear-leaf mite, *Phytoptus pyri*, which produces the disease known as the Pear-leaf blister, the spots being reddish, sometimes quite crimson, and in other parts of the leaf whitish green. In bad cases the leaves turn black, and then brown, dying; and sometimes the wood is affected. The damage is caused by the mites biting the tender tissues and depositing eggs in them, which soon hatch into minute whitish creatures that give rise to the blisters. The second parasite is the Pear-leaf blight fungus, *Entomosporium maculatum*, which gives rise to dull reddish spots on the upper surface of the leaf, and later on the under side, and finally the leaf, or part, becomes brown and dead. Very young leaves curl, and the young shoots die at the points in consequence of the attack. The third disease is the Pear blight, or "fire blight," which attacks the young shoots, leaves, and even blossoms. It is a *Schizomycetes*, or bacterial body, named *Micrococcus amylovorus*. Spraying with petroleum emulsion—the soluble petroleum insecticide advertised—acts effectively if applied in time. It may be used as a check in summer, directing the spray against the under side of the leaves, and thoroughly in the winter. In pruning remove the affected parts, cutting to sound wood below, and burn them. After this is done, and the petroleum emulsion is used early and occasionally, the insidious foes make little or no headway.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (R. L.).—1, *Anemone appennina*; 2, despite excellent packing the flowers had fallen on arrival, perhaps you could send some more in the early bud stage; 3, *Pteris cretica* var.; 4, *Begonia Meyselliana*; 5, *Calathea (Maranta) zebrina*; 6, *Cyperus alternifolius*. (Z. D. R.).—1, *Dendrobium densiflorum*; 2, *D. thyrsiflorum*; 3, *Oncidium flexuosum*. (J. McC.).—1, *Anthericum variegatum*; 2, *Agapanthus umbellatus variegatus*; 3, probably a *Hymenocallis*, but flowers are necessary for positive identification; 4, *Kerria japonica* fl.-pl. (A. E. D., *Cannell*).—*Cryptomeria japonica*. (A. L. S.).—A varietal form of *Clivia (Imantophyllum) miniata*. (P. J. P.).—The *Cypripedium* is a small flower of *barbatum*. The Zonal *Pelargonium* is very fine, but we cannot give its varietal name. Send it to Pearsons of Chilwell or Cannells of Swanley, with a stamped envelope for a reply, and they will assist you. (H. O. E.).—1, a form of *Selaginella Martensi*; 2, *Davallia immersa*; 3, undeveloped frond, possibly *Lastrea patens*; 4, *Cyrtomium falcatum*; 5, *Pellaea hastata*; 6, *Selaginella uncinata*. (A. W. J.).—*Lycaste (Maxillaria) Harrisonæ*.

TWO FEATHERED FRIENDS.

IGNORANCE is always to be deplored. The ignorant are shut off from so much pleasure and culture (rather we should put culture first). Of course the caviller will argue that what a man does not know of he never craves for. True; but there are at times, in the most ignorant soul, vague longings and yearnings after better things. It is curious we should be so blind to the many workings of Nature on every side. If we knew a little more of her methods, we could help rather than hinder her useful and valuable processes.

It is astonishing, for instance, how few of us, whose lives have been passed in the country, have taken up or studied, in its varied aspects, bird life. Our bird life is so abundant and varied. This temperate clime is so favourable to incubation—our varieties of soil afford every kind of food—the face of the country is so varied, that there are suitable haunts for all manner of birds. We are rich in the home product, so to speak; we are rich in the migratory species, and once in a century arises a man like Gilbert White or Charles Warterton. We do not expect every countryman to be a born naturalist, but we might reasonably have expected to find a little more general knowledge relating to the habits of our feathered friends. We take focus for

friends; we underrate the foe, we undervalue the friend. We are like gamekeepers—hostile to everything save our own particular charge. Even the pugnacious thieving sparrow has its adherents, and the maurading crow; both have done good work, both are capable of great mischief. Both have been allowed to overstep reasonable limits. They were accorded a little grace, they have now become our masters.

Of the two birds of which we would speak, one is most graceful in form, most elegant in motion, and possessing rich glossy plumage. *Hirundo rustica*, or swallow, comes to us about the middle of April, and takes its leave the latter end of September or early in October. In fact the duration of its stay depends upon the duration of insect life. Sometimes, poor birds, for the first few weeks their meals must be scanty. It is not the swallow that makes the summer, and if cold winds prevail and frosty nights follow insect life is checked, and insectivorous birds have but a sad time of it. We remember one very cold spring finding many dead swallows. We do not think it was the cold that had killed them, but, from their attenuation, lack of food.

They wage war on flies of every kind, many gnats, small moths, and beetles on the wing. They may be seen, too, picking up such insects as are found on the ground. As their food is entirely insect life, it would be a nice calculation to arrive at the number of deaths they are guilty of during a long summer's day.

When large gnats, such as "daddy longlegs" and crane flies merge from the pupal state, towards the end of summer, and in their heavy flight pass over fields and lawns, the swallow is there awaiting them. Perhaps, however, it is the Hop planter who owes them the greatest debt of gratitude. His is a precarious calling; the poor Hop plants are liable to attacks from so many enemies, and from one of these enemies the swallow does much to free the Hop bine.

It is a curious fact, and one worthy of note, that since the swallow has been on the decrease during the last fifteen years, the Hop flies or aphides of *Phorodon Humuli* have terribly increased. This blight, the result of the fly attack, is now almost annual instead of occurring as it used to do once in every three or four years. When the aphides leave the Hop gardens for their winter quarters on Plum and Damson trees, the swallow is in wait for them, and does make havoc in their ranks; but where are the swallows? Whose fault is it that they are not here?

The swallow is not a bird that our boys torment, they, or the most of them, treat this foreign visitor with fair courtesy, but it is the wretched little quarrelsome sparrow, *Passer domesticus*, which has driven away the swallow. He is always with us, winter and summer, and being on the spot, seizes and holds by main force the best nesting places, and keeps them against all comers. This is one of the outcomes of the sentimental cry, "Oh! spare the sparrow; he is the farmer's friend." He is all very well in the proper place, but he now has got beyond all bounds, not only doing vast harm himself, but driving away those birds which are of the greatest value.

Then, again, the swallow's wing is of beautiful shape, the colour fine, and Fashion says, "Trim with wings; all sorts, every kind;" and the death warrant of the swallow is sealed. What can we say? Shame covers us as with a garment, and we blush for our sisters, who are sinning so ignorantly.

The second bird which is such a friend to the husbandman is also a summer visitor, the spotted fly-catcher, *Muscicapa grisola*. It is hardly here as soon as the swallow, and does not come in such large numbers, and possibly is not so well known.

For years several pairs have nested in our garden, and we notice their arrival directly, not so much from their colour, as for their quick, sharp flights; hawking flights, one might say; nothing but insects—moths, flies, beetles and aphides. A pair were watched one day, and they brought food to the nest 537 times, and as they would bring as many as four and five flies at a time, they prove pretty clearly they have a mission which they fulfil. Proof is wanting that this bird is injurious to fruit; no remains have ever been found in the

stomach. True, they are among the fruit, for it is there they have their happy hunting grounds.

They, too, are of immense value to the Hop-grower, and do their share in destroying the dreaded flies. The saw-fly, the pest of Gooseberry growers, is also a favourite diet with them; their quick eye and quicker bill will do work that no human hand would undertake.

Why this valuable bird, with the swallow, should not be strictly preserved, we fail to see. We do not know our friends, or, if we do, we but tardily acknowledge their services. We find that abroad, in a certain measure, the swallow has a "close time." We might do worse than follow the foreigner's good example.

WORK ON THE HOME FARM.

The district reports in the agricultural papers have been lately amusing, as well as interesting. There is always a great diversity of opinion amongst them, which is natural, when the very widely differing conditions of soil and climate are considered; but we do not often see such flat contradictions as we have just now. One man thinks the weather and everything else perfect; another, only twenty miles away, has got little or no work done for a month, and writes in very low spirits. There must be difference of temperament here, as well as of soil and climate.

Much more rain has fallen, and some farmers have no doubt found much difficulty in finishing their spring corn sowing, and this only shows again the wisdom of getting on whilst the sun shines and the land is in good condition. Some farmers make rules not to drill before a certain date, but it is better to take advantage of favourable opportunities, even if they occur before the conventional time.

The same thing may be said as regards the Turnip crop, but the conditions must be good. Warmth is the important factor in growing young Turnips, and if May be cold and wet wait until June. We like to see a little reek of dust behind the drill, and if the sun be shining hotly, and the ground feel warm to the hand, keep the drill hard at work until all is finished.

Cabbages may still be planted, as the weather is more favourable than it generally is in May for young plants making a start. Mangold has not been easy to get in well, but with such abundance of moisture there should be an excellent plant, and all that is wanted is warmth and sunshine.

Spring tares sown now will be very useful in harvest. If not wanted for the horses, they will come in for the cows or lambs. The latter have generally been a good crop, and there has been less than the usual mortality amongst the ewes. Lambs are doing well, though pastures still are not great. Ewes must soon be clipped, and may be washed any time, the clipping taking place as soon afterwards as the weather is warm enough. We think the risk of losing ewes from too early clipping less than that of finding them dead after being overturned a few hours. They require very close and frequent shepherding just before clip-day.

Cattle are doing well out. There is not much grass, but apparently sufficient. Sunshine and a warmer wind are wanted.

REMARKS.

30th.—Frequent heavy cloud, but much bright sun.

1st.—Overcast all day.

2nd.—Alternate cloud and sunshine during day; overcast evening.

3rd.—Overcast and spots of rain early; alternate sun and cloud from 10.45; bright afternoon.

4th.—Brilliant and cool early; cloudy at intervals during day.

5th.—Brilliant early, and bright day, with cool N.E. wind, but hazy or cloudy occasionally.

6th.—Brilliant day, with cool N.E. breeze.

A fine week, average temperature, and a few slight frosts on grass.—
—G. J. SYMONS.

BARR'S PURE GRASS SEEDS

For Lawns, Tennis Courts & Cricket Grounds.

The following mixtures are composed of PURE GRASS SEEDS only, which have been thoroughly cleaned and carefully mixed. They cannot fail to give the most satisfactory results.

We sell the seed by weight, which is the only correct method of estimating quantity needed for a given space.

BARR'S "THAMES EMBANKMENT" GRASS SEEDS for Parks.—A special mixture which has been found very successful in many public and private parks and squares around London and throughout the country. Per lb., 1/3; per 10lb., 10/6; per 20lb., 20/-.

BARR'S "STANDARD" GRASS SEEDS for Garden Lawns, Golf Links, Cricket Grounds, &c.—In this mixture there is a larger quantity of dwarf, fine-leaved Grasses than in Barr's "Thames Embankment." Per lb., 1/6; per 10lb., 12/6; per 20lb., 22/6.

BARR'S NEW MIXTURE OF DWARF GRASSES for producing an Extra Fine Smooth Lawn.—A special mixture of the finest-leaved and dwarfest-growing Grasses, producing an EXTRA FINE VELVET TURF, and saving labour in not requiring frequent mowing. Per lb., 2/-; per 10lb., 18/-; per 20lb., 34/-.

Fuller particulars, with Hints on the Management of a Lawn, sent on application.

BARR'S NEW LAWN MANURE, "PHYTOBROMA," **WATSON'S LAWN SAND**, the best Weed Killer for use on Lawns. Full particulars on application.

BARR'S SEED GUIDE (free) contains a full Descriptive List of the best Vegetables and most beautiful Flowers, with many practical Hints on Culture, valuable to Gardeners, Amateurs, and Exhibitors.

BARR and SONS,
12 & 13 King Street, Covent Garden, London.
NURSERIES: LONG DITTON, SURREY.

CUTBUSH'S MILLTRACK MUSHROOM SPAWN

Everyone can readily grow Mushrooms, and by using this Spawn will ensure success. All growers speak in the highest possible praise of the quality. Numerous Testimonials. None genuine unless in sealed packages, and printed cultural Directions enclosed with our signature attached. Price 6/- per Bushel; or 1/- per Cake, free per parcels post.

CARNATIONS.

PERPETUAL OR WINTER BLOOMING.

BEST VARIETIES ONLY. CATALOGUE POST FREE.

W. J. GODFREY, EXMOUTH, DEVON

NEW ROSES.

PURITY.—The first English-raised garden Rose which has been awarded the National Rose Society's Gold Medal. Pure white, centre faintly flushed, of medium size and perfect shape, quite distinct. A grand new pillar and semi-climbing Rose, which should be represented in every collection. Each 5/-; 6 for 25/-.

R. B. CATER.—An important addition to exhibition Roses. Colour bright magenta-carmine, most beautifully shaded, of large size and perfect shape. Each 3/6; 6 for 18/-.

RUGOSA DELICATA.—A charming new Rugosa. Colour delicate soft rose. Flowers double, of good size, produced in clusters and always in bloom. Each 2/-; 6 for 10/6.

One sturdy plant of each variety for 10/-, including packing. New Catalogue of Roses in pots, including all the best of recently introduced varieties, post free.

FEEDING VINES.

NOW that the practice of cropping Vines much heavier than formerly has become general, the vital question of feeding demands special attention. It is quite possible to preserve Vines which are heavily cropped annually in perfect health and vigour for years, but to do so no half-measures in regard to feeding will bring about the desired results. The matter should be considered from a manufacturer's point of view, the nourishment in the soil being the raw material, which the Vine, by the aid of heat, air, and sunshine, converts into Grapes.

Fortunately we get the air and sunshine, and a certain amount of heat for nothing, but the solid substances necessary must be obtained from the soil; and although they form only a small proportion of the food required, it is, nevertheless, an undoubted fact that a large bulk of material in the shape of natural or chemical manures must be constantly applied to maintain the fertility of the soil. What a productive land Britain would be if all the cultivated soil produced as bountiful a crop as a well managed Vine border of ordinary dimensions does! I am inclined to think that a Vine growing in a cubic yard of soil will produce a heavier weight of fruit than any other tree. With good culture fine crops may be secured annually with as much certainty as a crop of Cabbages. Other fruits will sometimes play us false when given the best of attention, but the Vine is the gardener's steadfast friend.

Let us now deal with the practical part of the subject as to the best course to follow in feeding Vines. There can be no doubt that many cultivators have been in the habit of relying solely on manures, which, although good in their way, contain too large a proportion of nitrogen to form a perfect Vine food; but thanks to much valuable information on the chemistry of manures, which has recently received much attention, Grape growers are recognising the importance of applying additional phosphates in cases where animal manures are largely used.

The practice I find successful in keeping Vines in a vigorous condition, notwithstanding the heavy crops they carry, is the following. At the winter dressing we remove a little of the surface soil—and it is often only a very little, because of the network of roots; a surfacing of bone meal or Thomson's phosphate powder is then applied at the rate of 2 ozs. to the square yard. Over this is placed an inch layer of fresh loam, this in turn being covered with a layer of blood and slaughter-house refuse. A thorough watering is then given, and the surface is just covered with fresh loam. These materials form a substantial and varied fare, and perhaps some cultivators will think that so many layers would bury the roots too deeply. In reality, however, the depth of the combined layers is not more than 3 or 4 inches, and during the summer I find roots come to the surface and work freely through the mass.

During the early stages of the Vine's growth, plants such as Spiræas and Ferns are grown under the Vines. These are cleared out by the time the Grapes require thinning; the border then receives a "dusting" of lime, is slightly stirred upon the surface, and soon becomes sweet and permeated with active roots. When the thinning is completed a layer of well decayed town manure is given, and the border copiously watered. By closing the houses early with plenty of moisture at this stage the berries seem to swell as if under the influence of a magician's hand, but the only magic about the matter is the work of the glorious heat of the sun, and the plentiful supply of plant food brought within the reach of healthy Vine roots.

It seems to me that one of the greatest problems to be solved during the twentieth century is the gigantic one of how we can best turn to account the vast amount of sewage and refuse of our towns, which at the present time is wasted instead of being used to "replenish the earth." Let me, however, hasten to add that I am fully aware that nothing in the world is really wasted, it simply changes its form, and much of the sewage which now pollutes our rivers in time finds its way to the sea bottom, where, after future upheavals of the earth's crust, it may form rich alluvial soil upon which crops will flourish in the ages yet to come. Such refuse, then, is only "wasted" as far as the present age is concerned.

But I have wandered from the comparatively prosaic details of gardening of to-day into visions of the future; let us return to the Vines. After feeding to the extent already indicated some persons would be inclined to rest satisfied, but when there are heavy crops I feed with liquid manure up to the time the Grapes are fully coloured, then clear water only is given till the bunches are cut. With early and midseason houses I often apply liquid manure after the fruit is cut, unless the wood appears to be unduly strong, but such is seldom the case, it is more generally noted for its hard wiry appearance. It is only when natural manures alone are used that we get strong soft wood—or, perhaps I should write, "only when manures which contain too much nitrogen are exclusively used." In the case of Vines grown for the production of late Grapes, I discontinue feeding after the berries begin to show colour, unless at that time the weather happen to be exceptionally bright, as it is always an important matter to get the wood thoroughly ripe, or the Vines will fail to be satisfactory the following year.—H. DUNKIN.

BRITISH VINEYARDS.

MR. G. ABBEY'S letter in the *Journal of Horticulture*, 20th April (page 324), is in my opinion highly interesting. The list of English vineyards there given could easily be extended; Walham Green, Rotherhithe, Abingdon, and Lawrence Cottage, Isle of Wight, occur to me. The latter, along with Pain's Hill, Surrey, were still making wine in the present century.

The Swanbridge vineyard belongs to the Marquis of Bute, and so also the St. Quintin (I think that was the name), but this third one was abandoned on account of its exposure to rough winds from the Bristol Channel. I do not like to say anything unkind of the principality, but let those who know it best say if I am right or wrong in pointing out that it has more cloud, rain, and damp air from

the Gulf stream than Gloucestershire, the south Midlands, and the south and south-eastern counties.

Notwithstanding this, I do not see why cuttings from the Castle Coch vineyards should not furnish a hundred or two little plantations, on suitable soils on hillsides facing south to east. The idea of south in the compound south-west is misleading, this aspect getting the worst of the weather, and east is better than south-west unless this last has unusual and efficient shelter without shadow. I imagine the Gamay Noir Grape of Castle Coch is the most suitable, being the poor man's Grape of Burgundy, and would yield an encouraging quantity of wine to small Welsh growers.

Referring to Mr. G. Abbey's second letter in your issue of 27th April, page 336, I must repeat what I have said elsewhere, that the Duke of Norfolk's wine was fairly described as "excellent Burgundy," but that Lord Bute's wine at Castle Coch and elsewhere is by no means a model of what this country could produce, because, as aforesaid, the climate of Glamorganshire is too humid, and because red wine there has been the exception from the Gamay Noir Grape, in consequence of the want of a proper wine house in which to make the wine at a proper temperature.

We now want model experimental vineyards in the southern and south-eastern counties, in situations that are chosen for their position as regards drainage and exposure to the sun, without being swept by rough wind, rather than rich or valuable land. I suggest that landed proprietors should offer such sites, or express themselves as willing to further the matter. It must be remembered that if anything is done in this way, it has to compete with a very different state of matters across the channel. What we know as peasant proprietorship accounts for a great deal of the wine growing in France. Fortunately for the argument, Vine land is naturally cheap land, and whoever is willing to help the resuscitation of British vineyards should consider this.

The three red Grapes mentioned by your correspondent—namely, the Black Cluster, Miller's Burgundy, and Gamay Noir, are three of the best for making wines similar to claret and Burgundy. Sir Joseph Banks found the Miller's Burgundy Vine growing wild in an ancient vineyard in Gloucestershire. It is a reliable red wine Grape. The Royal Muscadine made pleasant light white wine in the Isle of Wight in the early part of the century. The Vines were planted too near each other, but whether this was a cause of the produce failing, and so helping the abandonment of the venture, I do not know.

Open air Vines should not fruit before their fifth year. They ought to be so treated as to justify Clement Hoare's assertion that their crop can always increase, and the Vine be the only fruit tree which in South Britain never loses its crop by frost. Lately I had to estimate for some friends what the return would be commencing the fifth year, and remembering that the fifth year might possibly be such as 1879 was, I replied only half a pound per Vine, though convinced, as I explained to them, that it would be 1½ lb. The crop permitted on Vines should always have respect to what the Vine should do the following year. It would take an old, well kept English vineyard to produce 6 lbs. per Vine. It is not impossible, but the approach to such a crop must be very gradual. I have seen vintages in Champagne and other districts where the weight per Vine was not over 2 lbs.; while in years like 1875 and 1893 the Vines ran from 6 to 10 lbs., and often more. The best years in France are our best years. I have occasionally had 6 lbs. on standard Vines.—H. M. TOD, 239, Goldhawk Road, W.

DOUBLE DAISIES FROM SEED.

IN answer to an inquiry for the method of raising these attractive flowers in the Royal Gardens, Windsor, referred to last week, we have been favoured with the following notes.

The Daisy seed is sown about the end of April, usually in shallow boxes out of doors in a shady position, and when large enough to handle, the seedlings are pricked into ordinary garden soil in our reserve garden in beds 5 feet wide (this width being a convenient one for hoeing and cleaning) in row 10 inches asunder, and the plants inserted 5 inches apart in the rows. Under this treatment by the end of the summer they make good strong plants, fit to plant out in the flower garden at the end of September or any time in October.

The Welsh name for this bright and cheerful "wee" gem of a plant is more appropriate and expressive, I think, than the English one, although at some time or other, I should imagine, the latter has been taken from the former, but, unlike the Welsh name, still retained. The English term has slightly lost its force in the name Daisy. In Welsh, the Daisy is called "Llygaid y dydd," which interpreted, means the "Eye of Day," or Day's Eye, now corrupted into Daisy. Why not revert again to the old name? It is much prettier, and expresses more truthfully one of the most charming attributes of these most cheerful plants, inasmuch, that the sun scarcely ever rises but is welcomed by the eye of one of its pretty open blooms.—O. THOMAS.

[In the notes on Windsor, on page 378, last week, the Mount Atlas Cedar was inadvertently printed "Cupressus" instead of *Cedrus atlantica glauca*.]

CYPRIPEDIUM POLLETTIANUM.

HYBRID Cypripediums, in their numbers, are fast approaching the time when one will have to use considerable discretion before recommending any particular variety; but *C. Pollettianum* (fig. 88) I can recommend to every lover of these beautiful plants. It is a compound hybrid raised from *C. calophyllum*, fertilised with the pollen of *C. oenanthum superbum*, and ranks in beauty with *C. triumphans*, *C. Euryades*, *C. Milo*, and *C. Adrastus*. It does not seem to be so well known as it ought to be, and many visitors express the greatest admiration on seeing it for the first time. A large plant with us is seldom without a flower. It is a good grower, in an ordinary warm Cypripedium house, potted in the mixture that has often been recommended for Cypripediums. The leaves show slight reticulations, and reach the length of 12 to 15 inches. The dorsal sepal is of a yellowish green colour, broadly margined with white, veined on the sides and middle with brownish crimson, and densely spotted with chocolate. The sepals and petals are greenish brown at the base, deepening at the extremities to a light purple brown, marbled with darker spots. It is a flower of good size, and altogether a most beautiful Cypripedium.

RENANTHERA IMSCHOOTIANA.

This is a remarkable plant, which produces flowers of an uncommon colour—namely, a deep reddish vermilion; and a plant which flowered freely last season is again vigorously pushing up its spikes. It is of small growth, and produces a spike some 18 inches long, well clothed with flowers. I find it thrives well in a small basket suspended quite close to the glass in a warm *Cattleya* house, and it should be grown in nothing but clean live sphagnum moss, well watered when in active growth, and only enough given it in the winter months to prevent shrivelling. It is a native of Cochin China, and on account of its colour deserves more attention.

MASDEVALLIA EPHIPIUM.

There appears to be a considerable amount of doubt as to when this interesting Orchid was introduced, and it seems to have had several names given it by the various collectors who were fortunate enough to find it. It is frequently called the Humming Bird Orchid, but not being an ornithologist I cannot see much resemblance to a bird. Be that as it may, it is a plant worth a place where the less showy and more curious Orchids find a home. This species is one of the largest of the genus, as the leaves sometimes reach the height of 8 or 9 inches, and its scape 12 or more high. The flowers are often 4 inches long, of a yellowish-brown tinged with red, with three reflexed yellow tails. *M. ephippium* succeeds well with the other *Masdevallias* of the *Harryana* type, but the old spikes should never be cut off, as they produce flowers again like *M. tovarensis*.

CATTLEYA MOSSIÆ REINECKIANA.

Though not, strictly speaking, an albino, this plant is much sought after by *Cattleya* lovers, and many growers consider it more beautiful than a true albino, on account of its highly coloured lip, which, with the deep yellow throat, forms a contrast with the snowy whiteness of the sepals and petals that is superb. There is much variation in the plants grown under this name, many of them having creamy white sepals and petals; but these are not to be compared with the white ones for beauty. *C. M. Reineckiana* thrives under the same conditions as the typical *Mossiæ*, but its flowers should not be allowed to stop on the plants too long, as this favours the weakening of succeeding growth, and I have seen plants nearly ruined from this alone. The plants are now pushing their flower spikes, and soon will unveil their beautiful flowers.

MASDEVALLIA MUSCOSA.

After looking at a large bank of the showier Orchids in flower, one turns with greater interest to those botanical curiosities, of which the above is perhaps one of the most interesting. It has been aptly called the Sensitive Orchid, as the least touch on the labellum causes it to close instantly. The plant is readily cultivated in small pans suspended quite close to the glass, potted in equal portions of prepared peat and moss, and placed in the cool house. The flowers, about three-quarters of an inch in diameter, are borne on slender scapes 5 or

6 inches high, and the leaves are 2 inches long. As in *M. tovarensis*, the flowers are produced from the old spike.

LÆLIA LATONA.

This most beautiful hybrid is again in flower, and it is astonishing what influence *L. einnabarina* has brought to bear upon its other parent *L. purpurata*, as it is almost exactly intermediate between the two. It is astonishing how the yellow from these small *Lælias* infuses into their offspring such lovely colours, of which we have several examples, such as *hippolyta*, *Maroni*, and others. *L. latona* was raised by Messrs. J. Veitch & Sons, and received a first-class certificate when exhibited on May 3rd, 1892. It will succeed under similar treatment to its parents, and is a most pleasing and delightful Orchid.

ONCIDIUM MACRANTHUM AND ALLIES.

These form a magnificent section of this large family of plants which will succeed in the cool house the whole year round. They produce their flowers on long twining, often branching spikes, the individual flowers on most of them being of large size. They should be grown in pots in a mixture of equal parts of rough peat and sphagnum moss, and the drainage must be perfect, as they require

FIG. 88.—CYPRIPEDIUM POLLETTIANUM.

large quantities of water when in active growth, but when at rest much less will suffice, though they must never be allowed to get dust dry. I will commence with *O. macranthum*, which is, in my opinion, the finest *Oncidium* yet introduced. It produces flowers from 3 to 4 inches across, with golden brown sepals and clear bright yellow petals; in fact it is too well known to call for any description. Many growers consider it short lived, but this is entirely due, I believe, to allowing their spikes to stay on the plants too long, as this greatly weakens them. It must be borne in mind that a spike several feet long needs much support, and when all the flowers are open I consider the spike should be removed. *O. chrysodipterum* is very rare, distinct, and handsome. The upper sepal is of a beautiful bright chestnut brown, with a narrow band of yellow. The two lateral sepals are wholly brown, while the much smaller petals are a bright gamboge yellow spotted with brown, and the lip nearly the same colour.

O. falcipetalum is not so showy as some of the others. It often produces a spike 20 feet long with flowers 3 inches across, the sepals of which are brown with a yellow border, the petals yellow, spotted with brown on the lower halves. It is a distinct plant that is seldom seen. A peculiar form is *O. lamelligerum*, and, like the others, bears flowers of different shades of brown and yellow, and when in bloom

the plant is very striking. *O. loxense*, perhaps the rarest of the whole section, has flowers quite 3 inches across, the sepals of which are a pretty greenish yellow, occasionally barred or blotched with brown. The petals are deep chocolate brown with a narrow yellow margin, and the large lip is rich orange with a few red spots at the base. It is a most beautiful plant when in bloom. *O. monachicum* resembles *O. lamelligerum*, and produces its flowers in the early spring months. They are a peculiar cinnamon colour, blotched and edged with pale yellow. As the name implies the flowers of *O. serratum* are crisped. In colour they are a beautiful brown, margined more or less with yellow; it is in flower at the present time.

The flowers of *O. superbiens* are not quite so large as some of the others, but it should be grown where room can be afforded. Like those previously named it produces flowers of various shades of chocolate brown tipped with yellow, some having white on different parts. *O. undulatum* is often confused with *O. superbiens*. I believe, however, that the true *undulatum* should be barred with purplish mauve on the petals, which gives the flowers an altogether unique and peculiar appearance.—J. BARKER, *Hessle*.

MILTONIA FLAVESCENS.

A couple of flowers of this species come from a correspondent for a name. It is a very interesting Orchid botanically, as it forms a kind of connecting link between the well known genera *Miltonia* and *Brassia*. The elongated linear segments are like those of most *Brassias*; they are a pale straw yellow in colour, the lip varying in different forms from yellow to white, with a few lines of reddish purple at the base. Though not altogether a showy plant its distinctness and pretty delicate colouring should insure it a place in collections. It is a native of Minas Geraes, where it was found early in the present century, but it was not introduced to British gardens until some years later.

PINE APPLES.

THE Pine Apple is a tropical plant, and its fruit, *Ananas sativus* or *Bromelia Ananas*, is so called from its resemblance to the cone of the Pine tree. It is one of the noblest and richest of fruits. The essential points to be kept in view in growing Pines are the potting, feeding, and atmosphere. If grown in pots or planted in pits the aim of the cultivator must be to obtain a mass of fibrous roots, without which well developed fruits cannot be expected, and to obtain such roots I have found no compost to surpass good turfy loam, with a liberal addition of fresh horse manure mixed three months prior to potting.

In preparing the suckers remove a few of the lower leaves, and with a sharp knife cut off about 1 inch from the base, inserting these in clean 5-inch pots containing loam and a fair quantity of silver sand, which should be made slightly warm by placing it on the boiler before use. Make the soil moderately firm, and, as I should have said before, crock thoroughly, as carelessness in this detail will probably spell failure. The pots must be plunged in a bed of prepared leaves and manure or tan, keeping the pots level, and about a foot apart each way, and give no water at the roots for about three weeks. Maintain the bottom heat at 80°, with an atmospheric temperature of from 70° to 90° according to the season of the year. Syringe amongst the plants every afternoon, but be most careful to keep water from their hearts, shading from bright sun, and keeping a brisk moist atmosphere.

The plants in six months will be ready for 8-inch pots, which they will occupy for a similar period under the same treatment. They are then placed into the fruiting pots, these being 12 inches in diameter, except for Providence, which requires a 14-inch pot. The compost for fruiting plants must be loam as already advised, with sharp sand, a sprinkling of crushed bones, and a 5-inch potful of soot to each barrowful.

In potting plants at this stage it is of the greatest importance to warm the soil before using it, and to use abundance of drainage, with turfy pieces above it. Pot very firmly, and see that the ball rests well down in the pot, to allow of the fresh compost being well rammed round the neck or collar of the plant to steady it. Replunge the pots at a distance of 2 feet each way, keeping the heat, both at the roots and in the atmosphere, at about 70° in the winter and 90° in the summer. Syringe every afternoon, but allow no water to reach the centres of the plants, as this results in deformed fruits, as does syringing when the plants are in flower. Immediately the fruits can be seen, feeding must commence, and it may be increased with the swelling of the fruit. During the flowering period care must be taken to prevent the slightest check, as this will result in malformation of the fruit. As soon as colouring commences withhold water from the roots, as the atmospheric moisture will suffice. The best varieties for summer use are The Queen, Ripley Queen, and C. Rothschild; for winter, Black Prince, Providence, Smooth Cayenne, and Black Jamaica. The Queen takes the palm for flavour.

For some reason that I fail to see Pines have of late years fallen

into disrepute in many establishments. Surely it cannot be on the score of expense. They require practically the same equipments as stove plants, and I am perfectly satisfied that the flavour of our English grown fruit will never be equalled by those that are imported.—H. MITCHELL, *Druidstone*.

INCURVED *versus* JAPANESE REFLEXED CHRYSANTHEMUMS.

I NOTE the Kingston Chrysanthemum Society has arranged classes in the schedule for incurved Japanese and reflexed Japanese varieties. I have seen in many parts of the country similar classes, but never a single competition that could be termed meritorious. Years ago the N.C.S. had similar classes, but they were dropped after an extended trial, as they produced little effect but plenty of wrangling. The difficulty is to define what varieties are eligible for inclusion. For example, Phœbus and Edwin Molyneux may at certain stages be classed in both sections. Generally speaking, Phœbus is regarded as a typical reflexed Japanese, but under some conditions of culture, and at various stages of development, it partakes of the incurved section. To see this and E. Molyneux staged in both classes would appear somewhat strange to an average on-looker.—E. MOLYNEUX.

SHEFFIELD CHRYSANTHEMUM SOCIETY.

THE usual monthly meeting of the members was held on the 10th inst, at the Westminster Hotel, when Mr. F. W. Littlewood read an interesting and instructive essay on "The Growth and Commercial Value of Different Trees." After adverting to the manner of the growth and the way in which trees take up nourishment, he referred at length to the difference of the grain of many varieties of timber as we see it when prepared for commercial purposes. He exhibited specimens of a great variety of woods to illustrate the many and varied ways in which trees build up their cellular tissue. The essay was thoroughly enjoyed by all present, and a lengthy and interesting discussion followed.

The exhibits were plants in bloom for the professionals, when the awards were—First, Mr. W. Topham; second, Mr. R. Agar; and third, Mr. T. Brewer. The amateurs exhibited cut flowers, and some excellent Roses and Orchids were staged with the other blooms. Dr. Banham secured first, Mr. W. Willgoose second, and Mr. W. Green third prizes. The plant exhibited by Mr. Topham was a specimen of *Anthurium Schertzerianum* carrying a large number of very fine spathes, for which the Society's certificate of merit was awarded. Dr. Banham exhibited some fine Roses in addition to his competitive exhibits.

The meeting was depressed by the news that Mrs. Matthewman, wife of the proprietor of the hotel, who was one of a party of the members of the Society and their friends who met with an accident to their conveyance on the previous Saturday after visiting Topley to see the show of Daffodils, was in a very dangerous state and not likely to recover, and who died on the following day (Thursday).

The usual routine business and the admission of a number of new members closed the meeting, prior to which a vote of thanks to the essayist, Mr. Littlewood, and to the Chairman, Mr. John G. Newsham, was passed.—J. H. S.

KIDDERMINSTER AND DISTRICT HORTICULTURAL SOCIETY.—The usual monthly meeting of this newly formed Society was held on Wednesday evening, May 10th, when a most instructive paper on the cultivation of the Tomato was given by Mr. A. Combes, of Hagley, for many years gardener at Himley Hall, Dudley. J. H. Watson, Esq., occupied the chair. Mr. Combes commenced with the history and introduction of the Tomato, giving practical details for its successful cultivation, with a reference to the diseases which have caused so much havoc amongst Tomato plants. As Mr. Combes is well known as a successful cultivator of most plants in the garden, his remarks were highly appreciated, a vote of thanks being accorded him at the conclusion of his able address. Though the Society has been formed since the commencement of the present year only, it has a membership of more than 150 under the presidency of Sir A. F. Godson, M.P., F.R.H.S., and an influential list of vice-presidents, and having met with so much public sympathy, the Committee proposes to hold a floral fête in August. Kidderminster being easy of access from most of the west Midland manufacturing towns, as well as being central for a thickly populated district, it is hoped the venture may prove a success. The Hon. Secs. are Mr. Thos. Rogers, Brookfield, Blakebrook; and Mr. F. Whicker, Summer Hill Gardens, both near Kidderminster.—W. H. W.

ROSE SHOW FIXTURES IN 1899.

- JUNE 13th (Tuesday).—Cambridge.
 „ 14th (Wednesday).—York†.
 „ 21st (Wednesday).—Isle of Wight (Shanklin).
 „ 24th (Saturday).—Windsor.
 „ 27th (Tuesday).—Westminster (R.H.S.).
 „ 28th (Wednesday).—Bath, Croydon, Maidstone, Reading, Richmond, and Ryde.
 „ 29th (Thursday).—Canterbury, Eltham, Norwich, and Sutton.
 JULY 1st (Saturday).—Crystal Palace (N.R.S.).
 „ 4th (Tuesday).—Gloucester and Harrow.
 „ 5th (Wednesday).—Brockham, Ealing, Hanley*, and Tunbridge Wells.
 „ 6th (Thursday).—Colchester (N.R.S.) and Farningham.
 „ 7th (Friday).—Hereford.
 „ 8th (Saturday).—Manchester.
 „ 11th (Tuesday).—Wolverhampton.†
 „ 13th (Thursday).—Bedale, Brentwood, Helensburgh, and Woodbridge.
 „ 14th (Friday).—Ulverston.
 „ 20th (Thursday).—Salterhebble and Sidcup.
 „ 22nd (Saturday).—Newton Mearns.
 „ 25th (Tuesday).—Tibshelf.

* Show lasting two days. † Shows lasting three days.

The above are all the dates definitely decided upon that have as yet reached me. I shall be glad to receive the fixtures of any Rose shows not named above, or those of any horticultural exhibitions where Roses are made a leading feature, for insertion in future lists.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

NATIONAL ROSE SOCIETY.

EVERY year, particularly during the spring months, speculations are rife as to what the rapidly approaching Rose season will bring forth, and each year the popularity of the queen of flowers seems to increase. The exhibitions to be held in June and July in various parts of the country are, according to the notifications that have already come to hand, as numerous as ever, and it is to be hoped that the season will bring success to all, whether they be exhibitors or not. That the National Rose Society has done much by its magnificent shows and its various useful publications to broaden and intensify the interest in Rose culture cannot be doubted, and it is more than probable that its influence will become greater as the years roll on.

This year of 1899 brings a departure from the custom that has prevailed of late in respect of the number of shows. There have, as all our readers are aware, usually been three, one each in London, the southern, and the northern provinces, and as a rule the metropolitan and the northern provincial have brought forth the finest Roses and the keenest competition. This year, however, there will be actually two shows, as the National Society, in place of the southern provincial, will join forces with the Royal Horticultural Society at the Drill Hall, on June 27th, when an admirable display may, weather permitting, be confidently anticipated. Of the two shows arranged, we have received schedules, and they will be held at the Crystal Palace and at Colchester respectively. Of the chief features we may give a few remarks, and at the same time inform our readers that full particulars and schedules may be obtained from Mr. Edward Mawley, *Rosebank, Berkhamsted, Herts.*

CRYSTAL PALACE.

On the first day of July this resort will be a palace of Roses as well as a palace of crystal, and it is hoped that thousands of visitors will testify their admiration of the national flower, and their appreciation of the efforts of the members of the great Society by attending. As usual, the day chosen is a Saturday, than which none other could be more favourable for visitors, though we have heard exhibitors from the provinces lamenting the fact that some other day was not chosen. This, however, we believe rests mainly with the powers that be of the Crystal Palace Company.

Five and a half dozen classes are enumerated, and of these the greatest interest always settles on those that are known as trophy classes. The principal one is for seventy-two single distinct trusses, to be shown by nurserymen. This always evokes the enthusiastic attention of everyone, as the premier exhibitor holds for the year the champion trophy, in addition to a small money prize and a trophy replica. There are also second and third prizes. Chief in the amateurs' section comes the class for forty-eight distinct single trusses, the first prize in which carries honours similar in character to the nurserymen's

section. Besides this, the amateurs have a Tea and Noisette trophy class for eighteen distinct single trusses, and the excellence of these three classes alone warrants a visit to the Crystal Palace by every rosarian. It must be observed by exhibitors that Regulation xviii. refers to the trophy classes, and runs as follows:—"In classes 1, 26, and 48 the blooms must be staged in boxes of the following dimensions—viz., twenty-four blooms in boxes 3 feet 6 inches long by 1 foot 6 inches wide, and eighteen blooms in boxes 2 feet 9 inches long by 1 foot 6 inches wide, all outside measurements." This is a new regulation, over which there was considerable discussion at the Society's annual meeting, and neglect of observance will inevitably bring disqualification.

Nurserymen and amateurs have several cups for which they can compete, as well as pieces of plate. These are placed at the disposal of the Society by amateurs and professionals interested in Rose culture, and include the Dickson cup for twelve distinct varieties sent out by Messrs. Dickson & Sons, Newtownards; a challenge cup for twelve distinct single trusses from Mr. Chas. J. Grahame; the Ramsay cup for a similar number of blooms given by Captain Ramsay; the Langton memorial cup for six distinct varieties of Roses grown within eight miles of Charing Cross; and a silver cup for twelve distinct varieties of garden Roses, the donor in this instance being Miss E. Willmott, V.M.H. The special prizes, too, are numerous, and prove that the interest of many members can be expressed in a very tangible manner when the occasion arises. The entries for the Metropolitan Show close on June 27th.

COLCHESTER.

On Thursday, July 6th, or only six days after the metropolitan fixture, rosarians will wend their several ways to the grounds of East Hill House, Colchester, where, in conjunction with the local horticultural society, the second show will be held. As the Colchester Shows are managed admirably by Mr. O. G. Orpen and the Committee the meeting should prove to be eminently satisfactory, especially if the weather prove favourable. Though this show is not really so important as the London one, the schedule comprises forty classes, so arranged as to meet the requirements of all sections—indeed, this careful attention to the differences that exist in the size of collections of various growers is one of the strong features of the N.R.S. There are trophies, cups, and pieces of plate, as well as medals offered, and as East Anglia has within its area some of the finest Rose growers in the world the show should be splendid in all respects—that is, if the date be favourable to all. Classes 1 and 17 are subject to Regulation xviii., which is quoted above.

The many readers of the Journal who are exhibitors of Roses will do well to note the addition to each of the schedules relative to the size of new boxes for Roses. It says, "The Committee recommend that any exhibitor requiring new Rose boxes should have them made of the following dimensions—all outside measurements:—

For 24 blooms	3 feet 6 inches	×	1 foot 6 inches.
„ 18 „	2 „ 9 „	×	1 „ 6 „
„ 12 „	2 „ 0 „	×	1 „ 6 „
„ 9 „	1 „ 6 „	×	1 „ 6 „
„ 6 „	1 „ 0 „	×	1 „ 6 „

The object of this is, of course, to eventually secure absolute uniformity of size in the boxes, which is not the case at present. It will take time to do this, as many exhibitors will not feel inclined to destroy their boxes wholesale, but will probably weed them as they become damaged or dirty.

NORTH LONSDALE ROSE SOCIETY.

WHEN the North Lonsdale Rose Show was first started in 1884, very few could have imagined that the development would have been so great or the success so continuous; but the people of Ulverston are workers, and it is pleasing to be able to record another successful year's working, judging from the report of the Committee which sat on Wednesday in last week, the Chairman being Mr. James Hodgson, J.P., C.C.

The report states that they had last season the largest gate money but one, that being when the National Rose Society visited Ulverston. The archery competition in connection realised the handsome sum of nearly £30. Regret was expressed at the death of Mr. Caird, a prominent supporter of the Society, and of the removal from the district of Mr. J. T. Marsden, the well known grower. The financial statement showed a balance in hand of £38 8s. 9d.

Mr. V. C. W. Cavendish, M.P., was re-elected President, Messrs. J. and W. Smith and Young on the Committee, Mr. F. J. Harrison Hon. Treasurer, and Messrs. F. W. Poole and G. H. Mackereth joint Hon. Secretaries. The business over, a pleasing recognition was made of the services of Mr. G. H. Mackereth, than whom no man has worked harder to bring the Society into the position it now holds. It will be remembered that the popular "George," as he is familiarly known to his friends, was married last autumn to Miss Dickson, a daughter of Mr. George Dickson, head of the celebrated firm of Rose growers, Alex. Dickson & Sons, Newtownards, Co. Down; and as the minutes

of the last annual meeting stated that some notice should be taken of the services of the Hon. Secretaries, the Committee felt the present time a fitting opportunity, at least in Mr. Mackereth's case. Mr. Hodgson in making the presentation referred to it as a pleasing duty. He had the greatest possible pleasure in presenting to Mr. and Mrs. Mackereth the pretty set of flower vases, and he hoped that they might be long spared to have Roses and flowers to fill them. Mr. Mackereth expressed his deep gratitude for the gift, saying that what he had done was because he loved the flowers, and that he was always willing to work for the good of the community.

The presentation consisted of a solid silver Rose bowl, standing upon an ebony plinth, with cover for fixing and displaying flowers; and two solid silver "specimen" vases, all very beautifully embossed, and of excellent design and workmanship.

The Committee is considering the advisability of holding a Chrysanthemum Show in the district, Mr. Keiller, of Conishead Priory, promising to stage 150 or 200 blooms. The usual votes closed the proceedings.—R. P. R.

NOTES ON FORCED FIGS.

EARLIEST TREES IN POTS.

AFTER the fruit forming the first crop is cleared from the trees, recourse must be had to syringing twice a day, also watering copiously at the roots with guano or other form of all-round liquid manure. That from manure heaps and stable tanks will be improved by a little superphosphate, about an ounce to a gallon of liquor. This will enable the trees to make more vigorous growth, and it is essential that the second crop be well nourished, and the wood not over-burdened with fruit. If the second crop fruits show very abundantly, they must be thinned, leaving those at the base of the current year's growth for the crop, and not too many even there, as the vigour must not all be expended on this, or the first crop next year will be prejudiced.

Trees ripening their fruits should have lessened supplies of water at the roots, but still afford sufficient to keep the foliage in good health, and discontinue syringing the trees. A circulation of warm air is necessary for the colouring process, leaving the top ventilators open a little at night, the highest coloured fruit being the best flavoured.

PLANTED-OUT TREES.

The first crop of Figs on the earliest started trees are now ripening, and until it is perfected, a little ventilation should be allowed constantly at the top of the house, and whenever the weather is favourable a free circulation of warm, rather dry air must be afforded. Cease syringing the trees directly the fruit commences to ripen, and avoid a superabundance of moisture about the house, but a moderate amount is necessary for the health of the foliage. If a good watering is given at that time, and the surface of the border is mulched, it will lessen the need of water during the ripening process; but trees with only limited space for the roots will need occasional supplies, and none must be neglected if necessity arise for the application.

SUCCESSION HOUSES.

Attention will be needed in stopping the young shoots at the fifth or sixth leaf, to induce a sturdy habit and shoots at the right place and proper length for furnishing the trees with bearing wood evenly in every part. Crowding, however, should be avoided by removing growths that cannot have ample room for development and exposure of the foliage to light and air, rubbing off such growths early. When the shoots are sturdy and short-jointed the terminals or extension growths should not be stopped, and only a judicious number of the side shoots be pinched to form spurs.

Strong-growing and long-jointed sappy wood is best removed, but if the trees produce much of that they ought to be marked for lifting and root-pruning, or they may have the growth checked by taking out a trench down to the drainage, cutting off the roots at about one-third the distance from the stem the branches cover of trellis. This will give a sudden check, and the trees responding by concentrating their forces on reproduction, fruitfulness ensues, and the fruit is aided in developing by the fibrous root action induced. Do not give so severe a check as to cause the leaves to fall, but when done judiciously summer root-pruning is better than winter, as a year is gained. Attend to syringing the trees twice daily, and water abundantly at the roots as often as required, employing weak liquid manure, especially where the borders are small.

UNHEATED HOUSES.

The trees are showing good crops, and will with favourable weather afford an acceptable supply of fruit in August and September. The roots being confined to narrow and well drained borders inside the house, they will require copious supplies of water, and the trees will need syringing twice a day in fine weather. In cloudy weather the afternoon syringing may be dispensed with, and in bright it may be performed early, with all the solar heat that can be shut in to secure the proper drying of the foliage before nightfall. The young growths should be trained a good distance apart, so as to admit light and air freely to the wood for insuring its ripening. Avoid close stopping without due attention to disbudding, as the results are the production of a number of late growths, which do not get properly matured before the leaves fall. The best course is to secure firm, sturdy, short-jointed wood. Allow the points of the shoots to grow up to the glass, and they will then form abundance of embryo Figs ready for swelling in the spring.—GROWER.

AN AMATEUR'S GREENHOUSE.

I AM not a little proud of the achievements of my small greenhouse, and I think that I have a right to be so, for throughout the year I have always plants in flower; at times it is quite gay, while there is always in it something to admire, and in the hope of encouraging others to work on the same lines, and to obtain a like amount of pleasure as myself, I think it may be useful to say what it has lately contained, what has preceded these, and what I hope will follow after; and first, let me give a description of the house itself.

It is 20 feet long, a span roof of 12 feet wide; there is a path running down the centre formed of battens, under which pots may be stowed, and bulbs that have done flowering may be placed until they are thoroughly ripened. On each side there is a stage 4 feet wide and about 4 feet from the ground; over the pathway, during winter, shelves are laid, on which many things are placed. The house is heated by an old-fashioned flue—of course, I am aware, not as pleasant as hot water, but in a place like this, where water is so charged with chalk that we have great difficulty in keeping our kitchen range clear, the same reason which induced me not to heat the church with hot water has led me to adopt the flue plan of heating.

Adjoining the greenhouse is a lean-to of about 12 feet long, which is not heated, and is really a sort of lumber room for plants when out of bloom and for others which may be coming on. In addition to these I have a few frames which one way or another give me some help in furnishing the house. I have just had the lumber house filled with a plentiful supply of spring flowering bulbs—Hyacinths, Freesias, Narcissi, Lachenalias, and Tulips. These have all now done their duty for this year, and the very early ones, such as the Paper White Narcissus, Roman Hyacinths, and early Jonquils, are regarded as annuals, and are thrown away when their time for blooming is over. The exhibition Hyacinths, of which I grow about three dozen, are either turned out into the border or given to friends to ornament their gardens.

TROPEOLUM TRICOLORUM.

I now come to what may be called the second act of this drama, and will try to give an idea of what the house is at present. Azaleas, Fuchsias, Cyclamens, Polygala Dalmatiana, Doronicums, Cinerarias, Sparaxis, Ixias, Salvias, Acacias, Tropæolums, Arums, Schizanthus, Agatheas, Primula obconica, Primula verticillata, Babianas, Eriostemon, Iris Morea, Aphelexis, Disa grandiflora, and Disa Veitchii. I have three plants of the Tropæolum tricolorum, which are now profusely covered with bloom. It is very odd that this plant is so seldom seen, for it is of very easy culture, and forms a beautiful and striking object when in flower. My tubers, after they have done flowering, I place under the stage, and there they remain until the autumn, and as soon as their slender white shoots show themselves, they are potted in a light mixture of peat, leaf mould, a little loam, and some sand. They make additional tubers every year, and these I am glad to give away, as I have not room for more than the three plants.

AZALEAS.

I have a few nice plants of Azaleas, and as I think it is always as well to have good things which do not take up more room than indifferent ones, I select some of the best Belgian varieties; in fact, the old English raised sorts seem to have been superseded by these newer varieties. The great mountains of bloom which we used to see at our metropolitan shows are completely gone, and the Belgian varieties, which are so free blooming and so delicate and brilliant in their colouring, have taken their place. My plants are about 18 inches high, and the same across, and I am obliged occasionally to get rid of them and get smaller plants. How do I grow them? After they have done flowering I sometimes repot them, but not always, and then place them in the annexe to which I have alluded. After they have made their fresh growth I put them out of doors, protecting them from heavy rains and not in a very sunny position, and there they remain during the summer, and when the autumn rains commence they are moved under cover. I do not think it is well to repot these hardwooded plants annually, at least for such purposes as I require them; in fact I have left them for two or three years and still my plants are covered with bloom. I at one time grew some Azalea mollis, but I have been obliged, owing to want of space, to give them up.

DORONICUMS AND SALVIAS.

I find Doronicum austriacum a very useful dwarf, hardy, yellow flowering plant for brightening up the house at this early season. It is perfectly hardy, and when the plants have flowered I remove them from the house, divide them, and plant them in some shady place in the open border, from whence they are lifted in the late autumn, potted, and put into a cold frame until a place is ready for them in the greenhouse. I have two or three plants of Salvia splendens, which are most useful during the winter, and which, although they are still in flower, have pretty well fulfilled their mission. The same exigency, want of space, compels me to grow only small plants, and then turn them out into the border, and prepare fresh plants from cuttings. Callas I referred to on page 370.

CINERARIAS.

With regard to Cinerarias, there are only two or three left now in the house, as they also formed part of the early spring arrangement. What a difference there is now in the cultivation of these flowers to that which I can remember. We know nothing now of named varieties or of propagating from cuttings, nor are we troubled now with the lanky plants which used to be grown. The raisers of seedlings have vied with one another in endeavouring to produce dwarf, sturdy plants, with brilliant heads of bloom. We continually see large collections of these at the Drill Hall, and very showy and beautiful they are. Of course, being seedling plants there is no necessity for trying to keep them on, and they are thrown aside when their bloom is over.

FUCHSIA SPLENDENS.

There is one species of Fuchsia which I have grown for many years that I rarely meet with—viz., *Fuchsia splendens* (fig. 89). It is an evergreen species from Mexico, with brilliant showy scarlet and green flowers, and has the valuable property of blooming throughout the winter. It requires no particular treatment, and is valuable for cutting, and altogether is one of the best of this beautiful tribe. I have mentioned Cyclamens, but they really formed part of my first houseful, and the few that I have now are the later blooming plants. They are of Messrs. Sutton's strains; and Vulcan, a very dark crimson variety, the darkest that I know, and Butterfly, a pure white of somewhat more expanded petals than the ordinary white varieties, are, I think, their two best, though the whole strain is good. After the plants have done flowering I stand them out along with the Azaleas. It suits me better not to keep the tubers beyond three years, though I have known them kept much longer, but then they occupy more room.

FIG. 89.—FUCHSIA SPLENDENS.

CAPE BULBS.

I always grow, at this season of the year, a few pots of those charming Cape bulbs *Ixias*, *Sparaxis* and *Babianas*. The first of these I find very difficult to keep from year to year, and there is one kind, *I. viridiflora*, with its peculiar striking green flowers, which I find impossible to retain; it may be most likely from some want of skill in my management of them, but for years I have tried to keep them, but have utterly failed to do so. With the other two I have no difficulty, and yet they are very closely allied, and come from the same part of the world. There is another bulb which I find particularly useful at this season—viz., *Allium neapolitanum* var. *Hermetici elegans*; it is an improvement on the type in the manner in which it throws up its trusses of blooms. I find it increases very rapidly, and that it is perfectly hardy, and comes up in all sorts of places in my garden.

SCHIZANTHUS.

As I have already said, I enlist hardy herbaceous plants like the *Doronicum* for the adornment of the house, so also the annuals help me, for I find no more effective or useful plant than the varieties of *Schizanthus*. I sow the seed of these somewhere about August, and when fit, pot them off three or four in a pot, and their bright colours and elegant foliage not only make them pleasant objects in the house, but they are very light and graceful for cutting and placing in vases. They vary very much in colour. I think the most striking one is *S. retusus*, but it seems also to be a difficult one, because the seeds do not germinate so well as the other varieties. Another plant which I find very useful is *Agatheae coelestis*, which I owe to the kindness of a friend. Some people call it a blue *Marguerite*, the colour is bright, and the plant is of very easy culture; I make fresh cuttings of it every year, so as to have small plants.

TWO PRIMULAS.

There are two *Primulas* which help to make up my mass of bloom, one is *Primula obconica*, about which we have heard a good deal as

to its irritating powers on the skin; it, too, is of easy cultivation, very free flowering, and easily propagated by the division of the roots; the other is *P. verticillata*, or Dusty Miller as some people call it; its whorls of yellow flowers make a pleasant variety amongst the other plants I have named. There are other things of which I have only single plants, and, as these die off from year to year, I do not think it is worth while to mention them. Of course all the plants mentioned in this notice will in a very short time be put out of the house, and I may then, perhaps, be able to show how I have filled up their places, and still keep my house gay with bloom, but I think that what I have already said justifies my remark, that I have very great reason to be satisfied with my small greenhouse.

Of course I could not have carried out all these arrangements had it not been for the care and energy displayed by my excellent gardener, who takes as much pride in our little greenhouse as its owner.—D., Deal.

PEACH BUDS DROPPING.

PEACHES grown in the open air may receive rough treatment by being frozen at night whilst in bloom, and within twenty-four hours saturated with winter rain, also undergo several weeks of drought in the summer, and yet will not drop their buds. That to my mind proves it is the artificial treatment under glass which causes disaster. I have at various times grown nearly all the varieties supplied by nurserymen in this country, and at the present time I have upwards of a dozen sorts planted under glass. These are without exception started gently into growth in December, so as to obtain ripe fruit as early as possible; and I have no hesitation in saying that it is impossible to grow some varieties of Peaches on the above lines without many of the buds dropping.

Watering and ventilation may be carefully attended to, still the fact remains that certain varieties will always cast their buds. I have heard gardeners affirm that if small-flowered varieties are grown there will be no trouble with buds dropping or the fruit not setting; but *Sea Eagle*, a large flowering late Peach, does not give trouble in this respect, and is a very free setter when forced, while the same may be said of *Dymond*. Among the small-flowering varieties that may be depended on are *Belle-garde*, *Crimson Galande*, *Belle de Doué*, *Royal George*, and *Barrington*.

Some of the worst varieties to cast the buds include *A Bee*, the different forms of *Grosse Mignonne*, and *Alexander*. The latter, when grown under glass does not cast its buds like the other varieties mentioned, but they appear to remain in a dormant state, so that there is often a difficulty in furnishing the tree with young growth. It is, however, not surprising that this should be the case when one takes into consideration the long season of rest it has after being forced; our fruit was all gathered in April this year. Some trees of *Alexander* that had been grown under glass for several years were lifted two years ago and planted against an open wall, and in this position they thrive remarkably well; every bud will form a shoot if necessary, clearly demonstrating that it is more at home in that position than when grown under glass.—S., Yorks.

ON SPRAYING FRUIT TREES.

IN my last note on this subject, of April 27th, page 335, I begged leave to give the results of a second dressing of caustic soda and pearlash, for the extermination of American blight. The solution consisted of 1 lb. caustic soda and 1 lb. of pearlash to 5 gallons water, instead of 10 gallons, as heretofore.

Mr. Hooper's remarks on spraying in Nova Scotia induced me to try this strength. Instead of using it in April, say from 20th to 25th, before the leaves expanded, I was delayed until 1st May, which I think rather too late. Its effects were unmistakeable. It was present death to blight, to the fresh growths of leaves, grass, and everything in a young and tender state. A trail of ants passing up and down the tree stems was killed instantly the spray touched them. The American blight turned black, and when examined next day had quite dried up. Whatever good the solution at this strength may be in winter, I have no hesitation in declaring it too strong for spring use. On re-perusing Mr. Hooper's article I note he uses caustic potash, whilst I used caustic soda. These substances are not identical, although both are of a burning nature; I point this out lest they should be taken for one and the same mineral, just as pinching and summer pruning are taken by some to be synonymous, but are not so.

My trees are freer from the grub of the codlin moth than in former years. This I attribute to the overhead spray. Should, however, this pest re-appear the Vermorel would at once be brought into action, charged with the following solution of Bordeaux mixture and Paris green—viz., Combine 6 lbs. copper sulphate and 4 lbs. quicklime with water enough to make 50 gallons. The copper sulphate is dissolved in water (hot, if prompt action be wanted), and diluted to about 25 gallons. The fresh lime is slaked in water, diluted to 25 gallons, and strained into the copper solution; after which the whole is thoroughly stirred with a stick. Both the copper and lime mixture may be kept in strong solution, as stock mixtures; but when combined should be promptly used, as the Bordeaux mixture deteriorates by standing.

It is one of the very best combined insecticides and fungicides when 4 ozs. of Paris green has been well stirred into it—viz., 4 ozs. per 50 gallons. As Paris green is a heavy powder, it must always be stirred before the knapsack sprayer is filled with it.—JNO. MILES, Southampton.

RECENT WEATHER IN LONDON.—The amount of rain that has fallen in the metropolis since Saturday last has been very considerable, though showers with intermittent sunshine have been the order of the day. On Tuesday a heavy thunderstorm visited the northern suburbs, and elsewhere rain fell heavily. Wednesday opened squally, but bright and fine.

— WEATHER IN THE NORTH.—Winter seems reluctant to relax his grasp. While there has been no frost during the past week, the north-easterly winds generally prevalent have been very chilling. The days have had little sunshine, and much rain has fallen, especially during the night. On Sunday a short sharp thunderstorm passed in the south; sleety showers occurred, but the afternoon and evening were rather milder. Monday morning was cloudy but not cold, with every promise of more rain.—B. D., *S. Perthshire*.

— MYOSOTIS AND WALLFLOWERS.—One of the simplest, but one of the prettiest, spring beds we have is composed of Wallflower Prince of Orange and Golden Bedder in round panels, the groundwork being all blue Forget-me-not. Both are now in full beauty, and the effect of the golden yellow against the sheet of blue is very fine. The bed is about 20 feet in diameter, so it is large enough to show at a distance. The position is so exposed that nothing very tall can be used even in summer, but these dwarf and strictly hardy plants fill the breach admirably in every way.—H. R.

— FRUIT GROWING IN WASHINGTON.—The State of Washington has been surely forging ahead during the recent years as a fruit-growing State. J. E. Baker, State horticulturist, has gathered some valuable figures showing the present orchard conditions. During the two years he has been in office 600,000 fruit trees have been planted, or nearly one-quarter of the total number of fruit trees in the State. The report shows that there are 2,414,626 fruit trees in the State, and of that number 1,410,194 are in the counties east of the Cascade range, and 1,004,432 in the counties west of the Cascades. Mr. Baker's estimate, says an American contemporary, of the value of the fruit crop of the State is between 750,000 and 1,000,000 dols. annually.

— THE ROYAL HORTICULTURAL SOCIETY OF IRELAND.—A Council meeting of the members of the Royal Horticultural Society was held at the offices, 61, Dawson Street, Dublin, on 9th May. Sir Percy Grace, Bart., occupied the chair, and the following members were present:—F. W. Burbidge, Esq., M.A., Major Domville, J.P., Rev. J. C. Hayes, M.A., D. Ramsay, Esq., H. Crawford, Esq., H. Smallman, Esq., and Greenwood Pim, Esq. The Secretary (Mr. W. H. Hillyard) having read the minutes of the last meeting, these were then passed and signed. R. Dunlop, Esq., and F. W. Sharpe, Esq., were proposed for membership, and were duly elected. Arrangements were made relative to the summer Rose show, to be held in Merrion Square on Thursday, June 29th. The proceedings were then brought to a close.

— EARLY POTATOES AND THE FROST.—It is surprising to note the effect in different gardens, quite irrespective of shelter or situation, that frost has upon early crops of Potatoes. It is usually thought that proximity to water has much to do with this question, and that gardens so situated are more likely to have the early crops injured than others. This may be so when the situation is very low, but the mere fact of the presence of water does not affect them. Here, in spite of careful covering, the points of the growth of Hammersmith Kidney, Ninetyfold, Myatt's, and other early varieties are crippled, though the situation is high and dry. At Kentwell Hall, Long Melford, on the other hand, there are beautiful rows with not a single blemished leaf, yet there is a full moat all round the garden, and no covering has been practised. Those having a fairly dry and light soil have, of course, a considerable advantage over others whose soil is close and heavy; but much may be done in the latter case by the addition of plenty of burnt earth and garden refuse—one of the most useful aids to culture of vegetables and fruit, inside and out. A little of it placed along the drills at planting time is of great assistance, encouraging the roots, and being very distasteful to slugs and snails.—H. RICHARDS, *Coldham Hall*.

— CROWN ANEMONES.—These are beautiful and varied plants, and no garden is complete without a few of them. The colours are wonderfully rich and varied, and in many old places, where the soil is light, they reproduce themselves from seed freely, countless variations occurring. The shape, too, varies considerably, and among the double forms are some exquisitely quilled and fluted flowers in almost every shade of colour. The tubers are very cheap, and in gardens where they do not flourish a succession may be kept up by lifting annually, enriching the soil with leaf mould, and making good any losses that occur by purchasing new stock.—T. G. S.

— GRAPE MADRESFIELD COURT.—This is one of the choicest and best of Grapes, and does well in small houses and borders. There are many small gardens where perhaps only one vinery exists, and this in many cases is filled with Black Hamburgh, to the exclusion of all other and better flavoured Grapes. This popular variety is, of course, one of the most useful, but there is always room for a change, and anyone looking for a good black Grape may do worse than plant Madresfield Court. It colours best under a good canopy of foliage, and a little lateral freedom should be allowed when the berries are colouring.—H. R.

— PLANTING OLD v. FRESHLY-CUT POTATO SETS.—There is much difference of opinion as to whether it is better to plant Potato sets the day they are cut, or to allow them to remain for several days, or even longer, before they are put in. To test the relative merits of both systems an experiment has been conducted at the Ontario Agricultural College, and the results go to show, says the "Irish Farmers' Gazette," that the best yields have been invariably obtained where the Potatoes were planted the same day as they were cut. The experiment has now been in progress for four years, and the average yield during that time was over eleven bushels per acre in favour of the Potatoes planted on the same day as they were cut, as against those not planted until four days after being cut.

— ISLE OF WIGHT.—The monthly meeting of the I.W. Horticultural Improvement Association was held at Sandown on Monday, May 8th, Dr. J. Groves, B.A., J.P., presiding over a good attendance of members. The Honorary Secretary (Mr. S. Heaton) gave an interesting lecture on "Horticultural Subjects," which was profusely illustrated with lantern slides, kindly lent by Messrs. Sutton & Sons of Reading. Mr. W. W. Sheath of Ventnor received the Association certificate for cultural merit for a magnificent collection of seedling Amaryllis. Ten new members were elected, which brings the total number to 350. A vote of thanks to the lecturer brought an enjoyable and profitable evening to a close. Arrangements for the Brook and London (Temple Show) excursions were made previous to the lecture.

— WATERING FRUIT BORDERS.—There is great risk now of vinery and other fruit borders getting too little water. The growing crops and ample foliage call persistently for moisture, and whether inside or out the borders soon get dry. Figs are very thirsty plants, and many a promising first crop of fruit has been ruined simply by want of moisture. The borders for this luscious fruit are not often made very large, for when planting young trees their shoots are frequently so vigorous that they need checking in some way, and a great amount of loose soil would be detrimental. But afterwards, when the borders get full of roots, feeding is necessary, and this means moisture. Grapes and Peaches or Nectarines, again, after the stoning is finished, lay on flesh rapidly, and unless abundance of moisture is present they will suffer. Bud dropping in early forced trees of the latter is often caused by lack of moisture just at the period of finishing up the growth, and thus the ensuing season's crop suffers from neglect in the present. Pot trees need even more feeding and moisture, and in every department where fruit is grown there is room for ample supplies now.—B. S. E.

— SINGLE WALLFLOWER EASTERN QUEEN.—A good strain of this beautiful and distinct variety is one of the most attractive of the Wallflower family. I have before me a bed of it, each plant being one mass of bloom, the flowers in their different stages varying from creamy white to pinky apricot. The habit of the plant is dwarf and compact, and the terminal flowers are well advanced before the lower ones begin to show signs of decay, which gives it added effect. If planted in conjunction with Little Giant or any other good strain of a dwarf-growing dark variety the effect is striking and beautiful. Amongst the lighter shades Primrose Dame, Golden Beauty, and Tom Thumb Golden are distinct and pleasing, but Eastern Queen seems more in keeping with the present day fashions.—GEO. PAXTON. [Our correspondent sent us a charming bouquet of these delightful spring flowers, amongst which, besides the novel colours, Dickson's Golden Queen and Selected Red were highly effective.]

METEOROLOGICAL OBSERVATIONS AT CHISWICK.

The weather has been dull and dry with variable cold winds. The only measurable quantity of rain which has fallen this month was on the 13th.

THE ROYAL GARDENERS' ORPHAN FUND.

IF of any satisfaction to "Another Country Gardener," I will at once freely acknowledge that I did not understand the working of this Society. If subscribers are satisfied, outsiders have nothing whatever to do with it. I may, however, remind him that "A. D." whom I presume is a subscriber, asked, on page 153, "To what is this indifference on the part of gardeners due? Can anyone explain it?" On page 257 I stated what the feeling was among subscribing gardeners in the provinces. This was corroborated by "A Country Gardener." But all the information "A. D." gave, on page 302, is an exercise in figures—namely, "that a sum of £50 was allowed for office expenses to the then Secretary. Now that the salary of 100 guineas includes the 50 guineas formerly accorded for that purpose, and pay for clerical help, the actual pecuniary recompense cannot be more than 50 guineas per annum." "A. D." has endeavoured to prove (but has not succeeded) that two fifties do not make a hundred. If the above is satisfactory to "Another Country Gardener," there are many others who will reasonably ask why it is necessary for the Secretary to pay 50 guineas a year for clerical help? If he devoted the whole of his time to the work for which he is paid, this would not be necessary. Also if a gardener subscribed for a given number of years, and should his children unfortunately require assistance, what security is there that they would obtain it from the above funds?—S., Yorks.

[Our correspondent is not aware that both the late and present Secretary, as well as others who helped in the formation of this excellent charity, were, in addition to the time they gave in doing so, pounds out of pocket in meeting initiatory expenses, and the last thought of any of them was to have the outlay refunded. If "S., Yorks," were condemned to live and pay rent in or near London and "devote all his time" to any particular object for 100 guineas a year, he would, no doubt, complain strongly, and with much better reason than he has now, of that amount being paid for the purpose suggested. If all the gardeners in the kingdom, who are as well able to subscribe 5s. a year as our friend "S." is, were to become active members of the well-established Fund (that has already done untold good), no long time would elapse before at least one child of a deceased subscriber would, if in need, receive substantial assistance. More than one child of a family has already been a beneficiary. Far more than the secretarial and management expenses are met by the generous gifts of friends who are not gardeners. The greatest mistake made in the increase in the Secretary's salary was in deferring it so long. We hope that as every penny subscribed by gardeners actually goes to the indigent children of their deceased brethren of the craft, our acute correspondent will not be content till he sends us a donation to forward to the Secretary, and if it be a good one "A. D." will not mind the little pleasantry indulged in in the above critique. It is largely by secretarial efforts in various ways that hundreds of pounds are obtained for the charities which they represent, and not a few of such officials earn their salaries over and over again. We are not inclined to publish any further letters, that, though not in the least intended to do so, may have a tendency to injure rather than help the highly useful and carefully managed Royal Gardeners' Orphan Fund.]

NATIONAL AURICULA SHOW.**NORTHERN DIVISION.**

THE annual exhibition of the Northern Division of the above Society was held in the Coal Exchange, Manchester, on the 5th inst. The Show was, at one time, part of the spring exhibition, but an alteration of date in this fixture led to a change. Subsequently the growers of Auriculas had an exhibition of their own at the Society's gardens. The more recent shows have been held at Middleton. In that town the cultivation of the flower is very popular with amateur gardeners, the records show-

ing that exhibitions of Auriculas were held there 150 years ago. For a variety of reasons the Committee decided on a return to Manchester. The present Show was, in point of excellence, equal to its predecessors. Its features included new varieties exhibited by Mr. Tom Lord of Todmorden, Mr. Ben Simonite, and Mr. R. Gorton of Eccles. The premier prize for the best Show Auricula was awarded to Mr. T. Lord for Abraham Barker, and Mr. A. R. Brown, Handsworth, Birmingham, gained a similar distinction in the Alpine class. Mr. H. Stringer exhibited the best plant of Polyanthus, to which the premier prize was awarded, and Mr. Frank Law of Sale put up a fine collection of Narcissi. The following is a list of the principal awards.

For six dissimilar Show Auriculas the first prize went to Mr. T. Lord, the second to Mr. B. Simonite, the third to Mr. A. R. Brown, and the fourth to Mr. J. W. Bentley. Four dissimilar.—First Mr. T. Lord, second Miss Woodhead (Halifax), third Mr. W. Shipman (Altrincham), and fourth Mr. J. Clements (Birmingham). Pairs.—First Miss Woodhead, second Mr. Stelfox (Stalybridge), third Mr. W. Kershaw (Ashton-under-Lyne), and fourth Mr. R. Gorton. Single plants, green edges.—Mr. T. Lord secured the first, second, and fourth prizes, and Mr. B. Simonite the third prize. Single plants, grey edges.—First Mr. B. Simonite, second Miss Woodhead, third Mr. T. Lord, and fourth Mr. J. W. Bentley. Single plants, white edges.—Mr. T. Lord secured the four prizes. Single plants, selfs.—First Mr. T. Lord, second Mr. J. W. Bentley, and the third and fourth prizes fell to Mr. B. Simonite.

In the Alpine section, for six dissimilar, shaded, the first prize was awarded to Mr. A. R. Brown, the second to Mr. J. Beswick (Middleton), the third to Mr. R. Gorton, and the fourth to Mr. T. Lord. Four dissimilar.—First Mr. J. Beswick, second Mr. J. W. Bentley, third Mr. T. Lord, and fourth Mr. A. R. Brown. Pairs, dissimilar.—First Mr. J. Clements, second Mr. T. Buckley (Stalybridge), third Mr. J. W. Bentley, and fourth Mr. S. Wardle (Ashton-under-Lyne). Pairs, for maiden growers.—First Mr. S. Wardle, second Mr. R. Holding, and third Mr. P. Holdam (Middleton). Single plants.—The first, second, and fourth prizes went to Mr. A. R. Brown, and the third to Mr. J. Clements. Single plants, white centres.—The first, second, and fourth prizes to Mr. A. R. Brown, and the third to Mr. J. Beswick.

For Polyanthus, black grounds, three dissimilar.—First, Mr. H. Stringer; second, Mr. J. Blowick; third, Mr. J. Oldham, and fourth, Mr. G. Thornley (Middleton). Red grounds, three dissimilar.—First, Mr. G. Thornley; second, Mr. J. Beswick; third, Mr. T. Oldham. Single plants, black grounds.—First and second, Mr. T. Oldham; third and fourth, Mr. J. Beswick. Single plants, red grounds.—The three first prizes went to Mr. G. Thornley, fourth Mr. J. Beswick.

NATIONAL TULIP SOCIETY.

MAY 17TH.

THE sixth exhibition was held at the Royal Botanic Society's Garden, Regent's Park. The exhibition was somewhat small, but the blooms excellent. Many exhibitors were absent owing to the late season.

In the premier class (Barr's cup) for eighteen dissimilar Tulips, two feathered, two flamed, and two breeder of each class, Mr. J. W. Bentley, Castleton, Manchester, was placed first. The varieties were Clio, San Jose, Julia Farnese, Masterpiece, Chancellor, General Grant, Othello, Annie McGregor, Adonis, Excelsior, Ashmolus, Mabel, Rose Hill, Adonis, Goldfinder, Annie McGregor, Excelsior, and W. Parkinson.

For twelve dissimilar rectified Tulips Mr. A. D. Hall, Wye, Kent, was placed first with a fine stand. The varieties employed were Samuel Barlow, Count, Annie McGregor, Adonis, Proserpine, Sir Joseph Paxton, Sarah Headley, Aglaia, Lord F. Cavendish, Trip to Stockport, and George Edward. Mr. C. W. Needham, Royton, Manchester, was placed second with good flowers of Duchess of Sutherland, Annie McGregor, Clio, and Talisman; and Mr. A. Chater, Cambridge, third with good specimens of Black Prince, Modesty, Masterpiece, and Guido.

For six dissimilar rectified flowers, Mr. Bentley was placed first with San Jose, Mabel, Lilian, Farnese, Trip to Stockport, and Masterpiece. Mr. A. D. Hall was second with Attraction, Aglaia, Adonis, and Duchess of Sutherland; and Mr. C. W. Needham third. For three feathered Tulips, Mr. Bentley was again placed first with Modesty, Guido, and Masterpiece. Mr. A. Chater was second with Modesty, Masterpiece, and Adonis. In the class for three flamed varieties, Mr. A. D. Hall was first with excellent flowers of Talisman, Dr. Hardy, and Aglaia, and Mr. Bentley second.

For a pair of blooms, one feathered and one flamed, Mr. C. W. Needham was first with capital examples of Modesty and Samuel Barlow, Mr. Bentley second, and Mr. A. D. Hall third. The class for six dissimilar Tulips was a good one. Mr. A. D. Hall secured the first prize with a capital exhibit; the varieties were Lady Grosvenor, Wm. Lea, Adonis, Annie McGregor, Goldfinder, and Talisman. Mr. C. W. Needham was second, and Mr. A. Chater third. Mr. A. D. Hall was again first for three dissimilar breeders with Maid of Orleans, John Heap, and Annie McGregor. Mr. Bentley was second, and Mr. G. Edom, Walton-on-the-Hill, third.

POTATO "UP-TO-DATE."—Mr. E. Molyneux's strongly worded statement on page 385 may disconcert a few. But there is another side to the question. "Up-to-Dates" have been at the top of the London market for some time, and I know growers in the Lothians who are sending "Up-to-Dates" to London and getting £4 per ton for them F.O.B. Leith.—W. C.

A GAY CONSERVATORY.

THE show of Azaleas in the conservatory at Walton Lea (the residence of John Crosfield, Esq.) is at present very beautiful, and has been admired by many visitors. The photograph (fig. 90) gives but a very slight idea of the effect produced by the arrangement of the colours of the following varieties:—Alexander II., Apollo, B. S. Williams, Bernhard Andreas alba, Balsaminiflora, Criterion, Duc de Nassau, Eclatante, Emperor de Brazil, Iveryana, Illustris, J. B. Veronne, Louise Vervaene, Mad. Marie Van Houtte, Mad. Camille Van Langenhove, Medel, Mad. Van der Cruyssen, Othello, President, Roi de Holland, Roi des Belges, Reine des Pays Bas, Simon Mardner, Stella, Souvenir du Prince Albert, Striata, Sigismund Rucker, and Versicolor.

The conservatory is 40 feet long by 25 feet wide. There are two groups, arranged in the centre: the first with small plants of Azaleas, including mollis and Ghent varieties, with Ferns between them, and a very fine Rhododendron Veitchianum, 6 feet high, in the centre. The second group is composed of fine pyramidal Azaleas 7 to 8 feet high, with Araucaria excelsa in the centre. Acacias, Cytisus, Deutzias, with other flowers and Ferns, impart variety to this beautiful group.

At the end of the conservatory three Camellias are planted out, and in the side borders there are the following climbers covering the span roof:—Cobaea scandens variegata, Lapagerias alba and rosea, Passiflora, and Tacsonia.

Suspended from the roof are eight baskets of *Platycerium alcicorne*. In the ornamental wirework at the bottom of one of these baskets a wren has built her nest, a very unusual place for such a purpose.

Great care is taken with the Azaleas after they are out of bloom to promote fresh growths and the formation of buds for another season. With this object in view the plants are carefully watered, and kept free from thrips and other enemies. Though some of the largest plants have not been repotted for twenty years, they are still in a healthy floriferous state, and reflect no small credit on Mr. W. Kipps, the able gardener, and his attentive assistants.

AN HOUR AT SHIRLEY.

THE "Shirley hills," with the common and Pine woods, form a favourite rendezvous for thousands of town and City dwellers who from time to time find, as adults, a day of recreation from labour, and, as children, the equally enjoyed escape from schools. The district may be described as a health resort, secured by the Municipal authorities of Croydon for the benefit of the public. Though only some two miles from the most populous town in Surrey, the inhabitants of which number nearly 140,000, the plantations are alive, so to say, with nightingales, which seem as much at home during the season as if they were ten times as far from the busy haunts of men.

The name of "Shirley" is, however, more associated with Poppies than nightingales by horticulturists, because from the vicarage garden there emanated the chaste and charming strain by the aid of which thousands of gardens over the length and breadth of the land have been made gayer and homes innumerable more beautiful by the presence of these variedly attractive flowers.

The vicar of Shirley is not only a lover of gardens and of everything good that grows in them, but a thorough gardener. He is capable not only of directing soundly, but of doing work of various kinds as well as is done by most professionals in the craft, and in some things a good deal better than many. Take, for example, the pruning of fruit trees. They are not cut into fanciful shapes, but long branches are formed wreathed with blossom from base to summit, to be followed, weather permitting, by fruit as thickly packed as "ropes of Onions," rendering thinning as much a necessity outdoors as it is under glass in the case of overlaid Peach and Nectarine trees in pots.

It seems appropriate that the Secretary of the Royal Horticultural Society should be such a real and actual gardener as he is, and it was in his garden that an hour was spent the other day. His invitation arose from the promptings of a kind heart, and his last thought would be that any more would be heard beyond the acceptance, for the sufficient reason that the recipient was supposed to be an overworked, broken-down journalist, incapable of using the pen, and in need of a few days change and quiet rest. But devotees of the pen and of gardening will only rest when they must, and will work while they can, be it ever so badly; and thus the "days" of rest were cut down to hours, and Mr. Wilks must be content to feel himself a victim of the revival of his enfeebled guest.

The vicarage is not a modern ornate structure of pointed gables and florid architectural indulgences. There is nothing of pompous

villadom about it, as in so many instances where "show" rules supreme. No; it is an unpretentious home in which internal convenience and comfort were more considered than external display by the vicar who built it some half a century ago. In these respects it suits the present occupant exactly, but the garden, when he took possession about twenty years ago, did not suit him at all.

His predecessor it seems was a gardener in his way, and that way appears to have had a touch of originality about it. He believed in the mixed system. Some half dozen miniature kitchen gardens "all over the place," in association with patches of lawn, beds of flowers, and clumps of trees represented the good old man's ideal of what a garden should be. He no doubt enjoyed it, and such quaint old gardens possess a charm to persons who set greater store by a tangle or jumble than on the satisfactory development of whatever may be grown, and on the health-giving influences of sun and air.

Trees when first planted and for a time afterwards, may not be too numerous for furnishing the surroundings of a home, but when they grow unthinned year after year till they meet in persistent combat for the space they need, the result is not an assemblage of beautiful trees—not a garden at all, but a scene of spoliation, a wreckage, wilderness, or ruined plantation. How many of what might have been noble trees and handsome shrubs, are to be seen and grieved over at this moment in various parts of the country, and all for the want of timely, reasonable, rational thinning? They are in thousands, even millions, more's the pity, and the work of restoration under such circumstances is a task of no small difficulty.

Mr. Wilks had recourse to a thorough remodelling, and he has good reason to be satisfied with the results. Such trees and features as could be effectively retained were not interfered with, except they could be improved. For instance, the grand Holly hedge which forms the boundary along the highway was not likely to be otherwise than cherished. It is about 50 yards long, wide and lofty—a truly ponderous hedge, the equal of which is seldom to be seen. It is clipped annually in April, and the men are no doubt glad enough when it is done. The entrance to the vicarage is through this dense green screen.

On the right-hand side of the door, which faces north, a contorted stump-like object arrests attention. It is the trunk and lower branches of an old Wistaria, the growths of which are trained round the west and south sides of a verandah, which is a convenient and picturesque adjunct of the vicarage. It is wide and lofty, and as the wall of the building is covered with *Solanum jasminoides*, Roses, and other climbers, and the raised border at the base is made bright and sweet by appropriate flowers in spring and summer, the florally covered way forms a charming retreat during warm days early in the season, and on cool quiet evenings after sultry days; externally the verandah is covered with the Wistaria and *Clematis montana*, which also ramble up the wall above, producing festoons of charming flowers at this period of the year.

From the verandah we step to the lawn—an expanse of an acre or two, bounded by a semicircular line of Elms planted by the late vicar, with a bold frontage of Rhododendrons provided by Mr. Wilks. Here and there in the distance ancient Apple trees, the remains of past orchards, are left standing on the lawn, and clumps of Rhododendrons have been established. Other fruits have been honoured by positions, or the lawn and shrubbery have been honoured by them, for no trees are more ornamental when in their charming garb of spring, while they are attractive in a different way in the autumn. In the centre of the lawn a Dartmouth Crab gives first its chaste flowers and then its brilliant fruits. Mr. Wilks is an æsthetic-utilitarian, and happily combines beauty with usefulness on his admired lawn and its immediate surroundings. At the present time beauty predominates, as combined in the wealth of Apple blossom and glowing masses of Rhododendrons.

Nearer the house is the flower border—a broad frontage to a bank of shrubs, with fruit trees rising above them, a twisting walk leading behind to a secluded rockery, bright with established bulbs in spring, cool and refreshing by hardy Ferns in summer. But the lawn front is only massed with flowers towards the end of the present month. Throughout the winter it is furnished with choice Conifers, bright coloured evergreens, and Ivies, plunged over the rims of the pots in which they have been established for many a year. They are removed at this season and replunged in their reserve quarters for affording space for summer flowers, so that this prominent border is rendered attractive practically all the year round.

On the east of the vicarage a portion of ground is screened from the lawn, and there we find sundry frames, packed with plants of course, as lovers of gardening will pack them. Beds of various

kinds of flowers, not omitting Poppies and Daffodils; a model Beurré Hardy Pear tree, and a long, high-sided span-roofed house packed, like the frames, with a great assortment of plants between the large pots of Peach and Nectarine trees.

These trees, about two dozen, are free informal standards, laden with thousands of fruits. They are tall enough to walk under, and in looking upwards the fruits seem closer together than stars in the firmament. To the question, "Why don't you thin them, Mr. Wilks?" comes the quick reply, "They have been thinned; they have to be

(outside) for the winter, and brought under glass in February. The pruning resolves itself into a common-sense system of thinning, to prevent overcrowding in the summer, and the prodigious weight of fruit prevents any approach to luxuriant fruitless growths.

As has been said, the house is packed with plants. Along one side is a row of *Lilium auratum*, the increase from one bulb, remarkable for their vigour, with stems as thick as walking-sticks, and 6 feet high. There scarcely seems room for another pot, but where there is an opening for the apex of a Tomato plant it is directed to it, and pokes

FIG. 90.—THE CONSERVATORY, WALTON LEA.

thinned once, twice, thrice, and the difficulty is to know how far to go, and when to leave off. We left 300 dozen to ripen last year." The productiveness of the trees is extraordinary, and in no other way than by the very best of management could they be kept in such a healthy state as to produce and mature such exhausting crops year after year.

With well selected varieties a regular succession of fruit is had from early summer to the autumn; and all is done so easily. As the crops are gathered the trees are stood outside, put in order at the roots, and fresh soil given towards the end of the season, safely plunged

its way through as best it can to the upright glass sides of the structure, and scrambles up between the general stock and the Peach trees, thus by-and-by giving fruits to lean their ruddy cheeks against the glass. We hear of stolen crops in gardens, but this is like a stolen crop under glass, and if there is a house in England that yields a greater amount of produce for its size than this does it would be worth going far to see.

The model Pear tree mentioned is not in the house. It is what may be termed of natural pyramidal form, or, in other words, has been allowed to assume the shape peculiar to the variety. It is some

20 or more feet high, and about the same in diameter at the base. The tree was, no doubt, cut back once or twice during its early years, but since then there has been little or no shortening of the main branches; the production, however, of an undue number has not been allowed. The result of this "open door" policy to sun and air is seen in the long, cordon-like branches, emanating from the central stem, each clustered with spurs from end to end. Why so clustered? Because (1) there has been no violent shortening of the terminals to force into wood growth hundreds of buds that have in consequence been permitted to change into a blossom-producing character; and (2), when these were once formed they have been enabled, not only to retain their vigour, but to increase in number, because the distances of the branches are such as would enable an ordinary sized man to pass between them, if sufficiently agile, without losing his hat. This is decidedly better than a man losing his head when he has a knife in his hand, and prevents the fruit that he foolishly imagines will follow his thoughtless mutilations.

Much has been heard of "summer pinching" of late; trees of the pattern described need little, if any, summer pruning either, for the sufficient reason that they produce few lateral growths, often only sufficient to incite free sap movement, and this without shading the leaves of the spurs. When trees are brought into that condition they require very little pruning at any time, and in the case of not a few the work is completed in one operation some time before the fall of the leaves; but there are thousands of other trees, not at Shirley, to which those remarks do not in the least apply.

On the western side of his enjoyable lawn, and beyond its boundary trees, Mr. Wilks has another garden—a slice taken off a small field. Here there are Apple trees mainly, much younger than the model Pear, but pruned on the same sound lines for fruit production—i.e., each variety is permitted to develop its own habit, and all the pruner does is to give the trees the best possible chance to form fruit buds, by so regulating the branches that the sun's rays can pass freely between them when the leaves are fully expanded. The pruning thus amounts to thinning as may be required in the summer, and the first small leaf buds are changed into bold blossom buds accordingly. Hundreds of owners and so-called managers of fruit trees do not know this, though the number, one would fain hope, is steadily diminishing. Unfortunately many fruit tree butchers rejoice so much in their self knowledge, the true name for which is gross ignorance, that they read neither books nor papers, or they might take a lesson from Shirley through the medium of these lines.

Mr. Wilks grows his vegetables in this western annexe, and not these alone, for he has a mixed flower border there, not a mere attenuated strip 3 or 4 feet wide, but in places nearer four times that width; nor is this a higgledy-piggledy wild garden, however enjoyable such may be in its right place, but all the varied plants are cultivated, and the owner can march about amongst them and cut armfuls of flowers if and when required for church or other forms of decoration, and for making his friends happy by a parting gift for their flowerless homes.

And how deftly and neatly he does it. "You will take a few Daffodils, Mr. Scribe," and forthwith a handful is gathered from the bright dancing masses—not "old" flowers that are over in a day, but young and fresh that last for a week—and cutting the stalks level they are pressed down into a long strong envelope, a couple of india-rubber rings grip the "handle" with just the right pressure, yet without crushing the tender stems, and in a trice there is a bouquet, as someone said last week, "fit for a queen."

Just another word or two. Over the way is the church, a fine structure, with an architectural feature in the form of two transept arches, which are said, on the authority of John Ruskin, to be unique. The sacred edifice is far too large for the comparatively few parishioners, but others come from round-about, including Croydon, and fill it. Just as the venerable florist-vicar, "D., Deal," enjoys the trust and confidence of the people among whom he lives, so it is with the gardener-vicar of Shirley, and both should be, and no doubt are, happy men.

What can be said of the churchyard and its fine monuments? Only that for its size its equal in a rural parish has not been seen by the writer, whose journeyings have not been few or rigidly circumscribed. "God's acre" at Shirley is such a desired resting place, that it is only by the forced institution of very high fees to non-parishioners that it can be kept within anything like the limits of recent enlargements, and would soon extend far over the adjoining green fields. One memorial of the dead can alone be mentioned here, and there is not another like it anywhere. It is in marble, and on it is represented in bold relief a Coleus, a Dracæna, and a small-leaved Caladium. We

have a wealth of all those plants now, and beautiful forms are raised from seed in ordinary routine; but it ought not to be forgotten that the pioneer in their production was Christian Frederick Bause, who died on the 28th of October, 1895, as inscribed on the handsome monument.

As many readers of these lines well know, there is often much that is interesting to be found in, and suggestions to be obtained from, comparatively small gardens, yet it is feared many are passed silently because they are small and nothing else. It is a mistake, and it is certainly not conceivable that any lover of gardening with eyes to see and ears to ear, could be other than gratified, and in some measure instructed by an hour spent in his cherished garden with the very real gardener, whose name will go down to posterity as one of the "great" Secretaries of the Royal Horticultural Society, the Rev. W. Wilks, the popular Vicar of Shirley.

THE MARKET GARDENERS' OUTLOOK IN WORCESTERSHIRE.

TAKING it all in all, a policeman's life is not a happy one, and the same may be said of the market gardener's. Just think for a moment how many things he has to contend with. First of all there is our admirable climate; then, supposing he escapes the heat and the cold, and the frost and the drought, and the rain, and all the rest of it, there are the insect pests, the caterpillars, the red spiders, the aphides, and all sorts of things with names as long as your arm which nobody can pronounce. Supposing, however, the weather and the insects let him off lightly, what happens? Why, just as he is counting on a substantial increase in his balance at the bank, and perhaps spending a bit extra on the strength of it, he finds that the foreigner is cutting him out with things made in Germany, or France, or the Channel Islands, or Tasmania, or somewhere; or that there is depression in trade and he can't sell his "stuff" for half what it ought to fetch. When he does by chance once in a lifetime get a good season—well, we were going to say that the Town Council raises the rates, or there are subscriptions for schools or other ways of making the money fly; but if you believe what he says himself, and surely he ought to know, he never has a good season, so we need not go into that. The gardener is like the farmer—he always has something to grumble about, and if he did not have anything to object to, people would think there was something radically wrong with his internal organs.

So much by way of introduction. This year he is grumbling about the bad spring—and quite justifiably, too, for it has been one of the worst for many years. The weather has been simply—well, simply awful, from a gardener's point of view. After going round among the gardeners, and taking their opinions on things in general, the results of this investigation we now proceed to give.

Spring Onions (autumn sown) are not, perhaps, the pleasantest subject to start with, but as they practically commence the season we will begin with them. Considerable breadths are grown, and they have been a fairly successful crop, and satisfactory prices have been realised. Unfortunately not all the gardeners have had them to put on the market. When we come to Radishes, however, the tale as to success is very different. One of the gardeners said they have been a total failure, and taking an average crop as 100, this year's yield are represented by about twenty-five. Others put the figures somewhat higher, but all are agreed that the frost has done a terrible amount of damage to the Radishes. Some it cut up just as they were coming through. Others it made hollow in the middle and stringy, and so worth very little in the market. Some of the later sown ones had escaped lightly, and are fetching pretty good prices. Round Eckington way, where garden produce is about three weeks later on the average than in the Evesham gardens, we saw some of the best Radishes. Their immunity from frost injury was due to their having been sown later. Probably the Evesham gardeners know their own business best, but it would seem that a great mistake is made in sowing Radishes so early. It is true that if they turn out well good prices are realised, but only too often the crop is more or less a failure. Some of the gardeners are realising this, and going in for later sowing, and we feel sure that this is worth the consideration of the growers generally. Very early Radish growing is a speculation pure and simple, just as buying next year's crop of Asparagus is.

The mention of Asparagus brings us to this very excellent vegetable. The season is very late. Compared with other years little "grass" has been cut. True, one gardener we know of started cutting as early as the 1st of April, and he is far from being an April fool. Another large grower told us that two or three years ago he had at this time cut twelve or fourteen thousand, whereas this year he has only cut as many hundreds. When it does come in it will come with a rush, the season will soon be over, and it is feared that the

prices will be none too high. The lateness of the season is attributable to the cold weather, and not, as some people seem to think, to the blight or whatever it may be called, that has affected the Asparagus the last year or two. This rust which affects the plants, it may be mentioned, caused many growers to have dire misgivings as to the future of the vegetable in this locality, but it is now generally admitted that it was the result of the dry seasons more than anything else.

Some of the gardeners swear by soot for Asparagus, and though it is a very good thing to use, especially on some kinds of land, too much of it is injurious. It is a capital dressing for heavy land, and contains manurial properties in that it possesses a good proportion of ammonia, potash, and sulphate of lime, but care is needed in its use. Another thing that the gardeners should remember is not to keep the beds in cut for too many years. Nowadays careful gardeners do not keep a bed nearly so long as they used to, and though it is an expensive crop to bring out, it will, we think, be found to pay well to plant out fresh beds more frequently than they have been doing. We are not so sure about the benefit to be derived from planting in the now fashionable narrow beds, but the experience of the next few years ought to settle this vexed question one way or the other.

Cabbage are working off better than they were last year. Some of the gardeners have not been so fortunate, however, and describe the Cabbage as a "funny" crop. Some people thought they were going to make a lot of money, bought the crop on speculation before it was fit for market, and burnt their fingers pretty considerably. One thing against the crop was the fact that plants were very difficult to procure last year, and the ground was too dry to plant them, and consequently there are not so many grown this time as is the case some years.—("Evesham Journal.")

ROBERT FORTUNE, PLANT COLLECTOR.

[THE following narrative by Mr. W. J. Gordon, in the long established and altogether excellent serial, the "Leisure Hour," will be perused with interest by many readers of the "Journal of Horticulture."]

We have all heard of what the man deserved who made two blades of grass grow where one grew before, but what shall we say of him who not only introduced the Tea and other plants into India, but brought among us over 200 species and varieties from the Far East, most of which are now so established in our gardens that they seem to have been with us for ages? The man was Robert Fortune—aptly, and inevitably, named the most fortunate of plant collectors—who was born at Kelloe, in Berwickshire, in 1813, and died in the Gilston Road, Brompton, in 1880.

He began as a gardener's apprentice and worked his way up in about a dozen years to be Superintendent of the Indoor Department at the Horticultural Society's Chiswick Gardens; and he was afterwards for a short time Curator of the Apothecaries' Garden at Chelsea. When peace was made with China in 1842, Fortune was sent out as botanical collector by the Horticultural Society. He arrived at Hong Kong in July the next year, after a passage of four months from England, and immediately set to work by sending home *Chirita sinensis*, whose elegant Foxglove lilac flowers he found under the dripping rocks of the island's ravines, where the Ferns and creeping shrubs grew in crowds. On the hills he came across the yellow Orchid *Spathoglottis Fortunei*, which he promptly despatched after the *Chirita*. In August he was off to Amoy, whence "some very pretty Roses producing small double flowers of great neatness and beauty" were collected and sent to Chiswick. From Amoy he went to Chimoo, where he was attacked by the natives, and among the plants which were nearly destroyed in the fight was *Abelia rupestris*, which ultimately arrived safely in England.

His next hunting-ground was the island of Chusan, which he visited again and again. Here he met for the first time the beautiful *Wistaria sinensis* wild on the hills, where it climbs among the hedges and on the trees, its flowering branches hanging in graceful festoons by the sides of the narrow roads that lead over the mountains. The purple variety was already known in England, having been introduced in 1816 from Consequa's garden at Canton; but the white variety, which he afterwards found at Soo-chow and sent home from Shanghai, was new. From Shanghai he also sent home the beautiful *Cryptomeria japonica*, the Japan Cedar, a species of Pine of much the same character as the *Araucarias* of Chile and Norfolk Island, which is now to be found in every nursery, though it has not yet attained the height it does in its native land, where it furnishes the long poles that are generally to be seen in front of the Chinese temples. Another great find at Shanghai was the *Anemone japonica*, which he discovered in full flower amongst the graves of the natives round the ramparts.

To get to Soc-chow, which was not then open to Europeans, he had to disguise himself as a Chinaman, with pigtail complete. It was a dangerous game and nearly ended seriously. He went because the gardeners at Shanghai told him it contained a great many nurseries from which came nearly all the plants they had for sale. This turned out to be untrue, but he succeeded in bringing away the white *Wistaria* already mentioned, a fine new double yellow Rose, and *Gardenia florida Fortunei* with large white blossoms like a *Camellia*.

In the spring of 1844 he was back in Chusan, which he described in his "Wanderings in China" as one of the most beautiful islands in the world.

"In the mornings," he said, "the grass sparkles with dew, the air is cool and refreshing, the birds are singing in every bush, and flowers are hanging in graceful festoons from the trees and hedges. The new plants of the island, some of which I had discovered in the preceding autumn, I now saw in flower for the first time. Early in spring the hillsides were covered with a beautiful *Daphne* with lilac flowers (*Daphne Fortunei*): *Azalea ovata*, certainly one of the finest and most distinct plants of this kind which I have introduced, also grows wild on the hills, and was in full bloom at this period. A fine new *Buddleia* (*B. Lindleyana*) had a most graceful appearance, as its long spikes of purple flowers hung in profusion from the hedges on the hillside, often side by side with the well-known *Glycine* (*Wistaria sinensis*). Another plant, certainly one of the most beautiful shrubs of northern China, the *Weigela rosea* (now *Diervilla rosea*, the Bush Honeysuckle) was first discovered in the garden of a Chinese mandarin near the city of Tinghae on this island. This spring it was loaded with its noble rose coloured flowers, and was the admiration of all who saw it, both English and Chinese."

In January, 1845, he made a short visit to the Philippines with the object of procuring a supply of the beautiful Orchid *Phalænopsis amabilis*, which Cuming had sent home a few years before, but which was still extremely rare in England. Arriving at Manila he started for the Laguna, a large lake in the interior of the island, in the neighbourhood of which was a farmhouse where he stayed as guest. Making an Indian's hut in the wood his headquarters, he held there a sort of market for the purchase of Orchids.

"The Indians," he says, "knew the hour at which I should return to the hut, and on my arrival I generally found the ground in front strewn with Orchids in the state in which they had been cut from the trees, and many of them covered with flowers. The *Phalænopsis*, in particular, was singularly beautiful. I was very anxious to get some large specimens of the plant, and offered a dollar, which was a high sum in an Indian forest, for the largest which should be brought to me. The lover of this beautiful tribe will easily imagine the delight I felt when one day I saw two Indians approaching with a plant of extraordinary size, having ten or twelve branching flower-stalks upon it, and upwards of a hundred flowers in full bloom. 'There,' said they in triumph, 'is not that worth a dollar?' I acknowledged that they were well entitled to the reward, and took immediate possession of my prize."

It is worth noting that for the first example of this Orchid which Cuming had sent home the Duke of Devonshire gave 100 guineas. This huge plant of Fortune's, which reached Chiswick safely, was the largest specimen ever seen in Europe.

Returning to the North of China in the beginning of the spring, he remained there till the end of the summer, travelling between Shanghai, Chusan, Ningpo, and other parts of the interior, visiting them at intervals as the plants came into bloom. In this way a large number of Tree *Pæonies*, *Azaleas*, *Viburnums*, *Daphnes*, *Roses*, and many other plants, all new to Europe and of great beauty, were from time to time added to his collection and shipped to England.

China is not a pleasant place to travel in even now; in those early days it was really dangerous for a European to be found outside the few treaty ports. His difficulties and adventures must remain unrecorded here, with one exception, his encounter with the pirates, which will serve as an example. It was on his voyage from Foo-chow to Chusan, when he was the only European passenger on a native junk. They were about sixty miles from the Min river, when the captain and pilot came down to his cabin to tell him that they saw a number of pirates right ahead, lying in wait for them.

"I ridiculed the idea," he says, "and told them that they imagined every junk they saw to be a pirate; but they still maintained that they were so, and I therefore considered it prudent to be prepared for the worst. I got out of bed, ill and feverish as I was, and carefully examined my firearms, clearing the nipples of my gun and pistols, and putting on fresh caps, and also rammed down a ball upon the top of each charge of shot in my gun, put a pistol in each side pocket, and patiently waited for the result. By the aid of a small pocket telescope I could see as the nearest junk approached that her deck was crowded with men; I then had no longer any doubts regarding her intentions. The pilot, an intelligent old man, now came up to me, and said that he thought resistance was of no use; I might manage to beat off one junk, or even two, but that I had no chance with five of them. Being at that time in no mood to take advice or be dictated to by anyone, I ordered him off to look after his own duty. I knew perfectly well that if we were taken by the pirates I had not the slightest chance of escape; for the first thing they would do would be to knock me on the head and throw me over-

board, as they would deem it dangerous to themselves were I to get away. At the same time I must confess I had little hopes of being able to beat off such a number, and devoutly wished myself anywhere rather than where I was."

"The scene around me," he continues, "was a strange one. The captain, pilot, and one or two native passengers were taking up the boards of the cabin floor, and putting their money and valuables out of sight amongst the ballast. The common sailors, too, had their copper cash to hide; and the whole place was in a state of bustle and confusion. When all their more valuable property was hidden, they began to make some preparations for defence. Baskets of small stones were brought up from the hold and emptied out on the most convenient parts of the deck, and were intended to be used instead of firearms when the pirates came to close quarters. This is a common mode of defence in various parts of China, and is effectual enough when the enemy has only similar weapons to bring against them; but on the coast of Tokien, where we were now, all the pirate junks carried guns, and consequently a whole deckload of stones could be of very little use against them."

The pirate fleet were in a hurry to begin.

"The nearest pirate was now within 200 or 300 yards of us, and, putting her helm down, gave us a broadside from her guns. All was now dismay and consternation on board our junk, and every man ran below except two who were at the helm. I expected every moment that these also would leave their post, and then we should have been an easy prey to the pirates. 'My gun is nearer you than those of the jan-dous,' said I to the two men, 'and if you move from the helm depend upon it I will shoot you!' The poor fellows looked very uncomfortable, but, I suppose, thought they had better stand the fire of the pirates than mine, and kept at their post."

"The shot from the pirates fell considerably short of us, and I was therefore enabled to form an opinion of the range and power of their guns, which was of some use to me. Assistance from our cowardly crew was quite out of the question, for there was not a man among them brave enough to use the stones which had been brought on deck. Again the nearest pirate fired upon us. The shot this time fell just under our stern. I still remained quiet, as I had determined not to fire a single shot until I was quite certain my gun would take effect. The third broadside which followed this came whizzing over our heads and through the sails, without, however, wounding either the men at the helm or myself. The pirates now seemed quite sure of their prize, and came down upon us, hooting and yelling like demons, loading their guns, and evidently determined not to spare their shot. I knew that the next discharge would completely rake our decks. 'Now,' said I to the helmsmen, 'keep your eyes fixed on me, and the moment you see me fall flat on the deck you must do the same, or you will be shot!' I knew that the pirate who was now on our stern could not bring his guns to bear on us without putting his helm down, and bringing his gangway at right angles with our stern, as his guns were fired from the gangway. I therefore kept a sharp eye upon his helmsman, and the moment I saw him putting the helm down I ordered our steersmen to fall flat on their faces behind some wood, and at the same moment did so myself. We had scarcely done so when bang! bang! went their guns, and the shot came whizzing close over us, splintering the wood about us in all directions. Fortunately none of us were struck. 'Now, mandarin, now! they are quite close enough!' cried out my companions, who did not wish to have another broadside like the last. I, being of the same opinion, raised myself above the high stern of our junk, and while the pirates were not more than 20 yards from us, hooting and yelling, I raked their decks fore and aft with shot and ball from my double-barrelled gun. Had a thunderbolt fallen amongst them they could not have been more surprised. Doubtless many were wounded, and probably some killed. At all events, the whole of the crew, not fewer than forty or fifty men, who a moment before crowded the deck, disappeared in a marvellous manner, sheltering themselves behind the bulwarks, or lying flat on their faces. They were so completely taken by surprise that their junk was left without a helmsman; her sails flapped in the wind; and as we were still carrying all sail and keeping on our right course, they were soon left a considerable way astern."

Another junk now bore down, and the same tactics were resorted to, with the result that its helmsman was killed, and it was left with the sails flapping uselessly. Two other junks, when they saw what had happened, prudently forebore to venture nearer, and, the peril being over, up came the heroic crew to hoot and yell at the pirates they had a few minutes before held in such terror. Two days afterwards another pirate fleet appeared on the scene, to be beaten off in a similar way. Yet later on the Chinese crew, to whom gratitude appeared to be unknown, refused to complete their contract by landing Fortune in Chusan, and had to be brought to their senses by being threatened with the contents of the redoubtable double-barrel.

(To be concluded, with a portrait of Mr. Fortune.)

"FAMILIAR WILD FLOWERS."—Numbers 7 and 8 of this admirable publication contain plates of Lady's Smock, Bitter Cress or Cuckoo Flower, Wallflower, Yellow Horned Poppy, Shepherd's Needle, Red Meadow Clover, Anemone, Germander Speedwell, Garlic Mustard or Sauce Alone, Black Bryony, Cross-leaved Heath, Blackthorn, Hound's Tongue, Carrot, Corn Mint, Field Scorpion Grass, Lady's Mantle, Groundsel, Henbit, dwarf Thistle, and Starwort.

DEATH OF MR. MALCOLM DUNN, V.M.H.

ALL gardeners, and many more than gardeners, who enjoyed the friendship of the long and trusted gardener at Dalkeith Palace will mourn his loss most deeply, and their grief will not be the less because of the suddenness of the melancholy event. Apart from his liability to attacks of asthma, Mr. Dunn rarely showed signs of weakness. He was a man of great activity and energy, and with his high spirit was combined a warm heart. He was ever ready to help in whatever way he could the advancement of gardening, and to assist his fellow men. He was a subscriber to almost everything he deemed good in connection with the art he loved, and of which he was acknowledged as one of its most capable exponents.

Our first visit to Dalkeith unfortunately happened in Mr. Dunn's absence, but in response to an inquiry he promptly forwarded to us some particulars as to the extent of the glass department, which had impressed us by its magnitude. Our last intentional visit, a little more than two years ago, was cut short, so to say, on the threshold. On the evening of the appointed day he was summoned by telegraph into Perthshire, on the occasion of the sudden death of his sister, and his end appears to have been similarly unexpected, and equally sudden.

Mr. Dunn, who was a rather ardent politician, attended a Conservative meeting in good health and spirits on Tuesday night, the 9th inst., went home in a pouring rain, caught a chill, and peritonitis set in on Wednesday. He suffered much, the doctor attending him four or five times; death ensuing at half-past twelve on Thursday morning, May 11th. Age, sixty-one. We have thus health, sickness, death, crowded, as it were, into a span, as the subject of these lines was well on Tuesday, seriously ill on Wednesday, dead on Thursday, and buried on Saturday.

Just as we were commencing a brief record of the career of Mr. Dunn a tribute of appreciation arrived from Mr. R. P. Brotherston, and as it contains the chief incidents of his gardening and home life, it is inserted hereunder. Though our portrait (fig. 91) was taken some years ago it represented the deceased as he was to-day, as in appearance he had not aged materially.

The announcement in the Friday papers of the sudden death of the late Malcolm Dunn on Thursday last (May 11th) came as a great shock to the many gardeners who knew him. In physique Mr. Dunn surpassed the majority of men, and no doubt it was largely owing to having been blessed with a constitution of abnormal vigour that he was able to overtake the large amount of work that daily passed through his hands. By those who knew him intimately, a long stretch of years of working life was confidently expected, and indeed all who have lately come in contact with him have been impressed with his abounding vitality. Whether the fact that for a few years past the deceased gentleman thought it prudent to be a little careful in his dietary had any bearing on the acute inflammation of the stomach which after less than a day's excruciating suffering was the terminating cause of so bright a career cannot be said. We only know that a chill was caught either at or after a meeting he attended at Dalkeith on the Tuesday evening, that acute pain developed during the succeeding night, and on Thursday morning Malcolm Dunn was with those who sleep.

The general estimate of his age has proved incorrect, his years having been fewer in number than anybody seems to have guessed. Sixty-five to sixty-eight was the term one heard mentioned; as a fact, he was only sixty-one, but, a hard worker all his life, how much he had been able to crush into that period no one can ever rightly know. It is generally thought that Mr. Dunn was a native of the town of Crieff, in Perthshire; as a matter of fact, he was a native of the parish of Auchterarder.

Though for long years his family has been located at Crieff, he received the elements of education at the parish school, an institution that was devoted to teaching, as opposed to the cramming My Lords have seen fit to substitute. His gardening career commenced in Strathallan Gardens, where he served his apprenticeship. While there he botanised the district, and sometimes during the summer months passed the night out of doors in his eagerness to traverse as much ground as possible.

In 1859 he was in the gardens of Sprotsboro' Hall, Yorks, whence he passed to Trentham, and while there worked in the vineries. At this time the famous discussion on the identity of a certain Grape caused him to take a greater interest than he otherwise might have done in the large collection of varieties of Grapes then cultivated there. In 1861, at the early age of twenty-three years, he had charge of a garden and large orchard in Worcestershire, and there studied cider making, and obtained some curious information concerning the manufacture of "champagne," the details of which he was not averse to relate at the fireside of his friends.

Two years later the appointment to Powerscourt was received, and whilst there Mr. Dunn first became known through his successful treatment of Vines attacked by *Phylloxera vastatrix*. The whole of the roots of the Vines in four vineries were lifted, picked free of soil, then washed and laid back in the same material after it had been treated to a dressing of caustic lime and soot. Both the Thomsons commented favourably on the exploit, David in the "Gardener," and in "Fruit Culture Under Glass;" and William in the eighth edition of "The Grape Vine," and there is little doubt his appointment to Dalkeith Gardens, on the retirement of the latter in 1871, was largely due to the prompt and daring method he adopted in this case.

From sheer force of character, combined with untiring energy and a capacity for working hard, Malcolm Dunn gradually came to occupy a unique position among British gardeners. If he once took a matter in hand he stuck to it with dogged persistence, and, though no doubt unconsciously—for those who knew him best know how modest his real character was—he never seemed satisfied unless leading others. The various congresses at Chiswick and at Edinburgh owed much of their success to Mr. Dunn's hard work and push.

The reports on Apples, Pears, and Plums exhibited at the Edinburgh Congresses were written by him. The Forestry Exhibition at Edinburgh was also greatly benefited by his energy, and, indeed, in all matters relating to forestry he was looked upon as an authority as competent as he was in pomology and gardening generally. He was also a life member of the Highland and Agricultural Society, and was the only gardener whom the Directors of that

FIG. 91.—MR. MALCOLM DUNN, V.M.H.

Society have ever allowed the privilege of compounding for a life interest. His connection with the Royal Caledonian and the Scottish Horticultural Societies is well known, and it was only a few weeks since the latter Society conferred an honorary membership on its first President. He has been the recipient of the Veitch Memorial medal, of the Niel prize in horticulture, and was one of the sixty chosen as a Victoria Medallist of Honour, and of which body he is the first to pass away. About Mr. Dunn's qualifications or right to the latter position there was no doubt whatever among Scotsmen, and he himself was not a little proud of the distinction.

In estimating Mr. Dunn's position as a great gardener it is impossible to help contrasting him with his immediate predecessor, and perhaps also with Macintosh, and in gardening pure and simple it will perhaps be the general verdict that he did not reach the level of either. But the subject of our notice had difficulties to contend with of which they knew nothing. Both had unlimited means at command, while during almost the whole period of Mr. Dunn's operations the ducal estates were suffering from want of funds, and it is only lately they have regained a pleasant equilibrium in that respect. A re-arrangement of heating, and the substitution for a number of antiquated boilers three of the most modern type has been one result, and a long deferred wish of Mr. Dunn's was thus gratified only a few months ago. Many of the glass structures were equally out of date, and those only who have had dealings with worn out houses can appreciate the difficulties attending their management. Flower gardening in particular suffered, and one of the wonderful things about Dalkeith was how its chief managed to keep up to date with flowers.

His position as a hardy fruit grower calls for no comment, his knowledge on the subject having been almost encyclopædic. It was, I may venture to say, his hobby. His knowledge of trees was also most extensive, and a few years ago he took up hardy shrubs, adding year by year to the collection at Dalkeith any good thing he learned of. Pine Apples, I may add, were particularly well grown during all Mr. Dunn's time.

It is in broad and accurate knowledge of the subjects in which he was interested, some of these outside horticulture altogether, that we undoubtedly find the cause of Mr. Dunn's greatness. He was widely read, and possessed a large and well selected library of works on gardening,

forestry, and agriculture. Among the books upon which he placed the greatest value were Loudon's various works on forestry and horticulture, a complete set of "The Scottish Gardener" and "Gardener," and the copy of Hogg's "Herefordshire Pomona," which he chose when presented with the Niel prize. If I am not mistaken the oldest book in the library is a 4 vol. copy of Martyn's Ed. of "Miller's Gardeners' Dictionary," the purchasing of which in Dublin, and the regret of the street vendor who sold it that he had not asked for a bigger price, Mr. Dunn used to relate with much humour.

He early contracted a habit of note-taking, and it is a remarkable fact that the schedules of all the more particular shows at which he had acted as judge since 1861 have been preserved, and the points he made for his own assurance are figured on the margins. It has all along been his practice to decide no important prize without pointing. Then he was continually going about the country visiting estates, and by this means alone he gained a unique kind of knowledge with the outcome; as I heard a leading florist say lately, "To be acquainted with Dunn was of itself an education."

He was very largely consulted on matters connected with forestry, and one of his boldest experiments was the lifting a good part of an avenue of blown Lime trees at Duns Castle in 1880. The details of the work were entrusted to the late Mr. Alexander Shearer, long gardener at Yester, and an old *Journal* man, and with a success that has fully justified Dunn's advice. Mr. Dunn was for many years the organiser of the summer excursions of the Scottish Arboricultural Society, and it has occurred that the less vigorous of the members have found it impossible to keep up to the programme, drawn up for their benefit, no doubt, but beyond their physical powers to accomplish.

As a lecturer Mr. Dunn had more applications to speak than he would accept. He spoke very rapidly, most instructively, but perhaps tried to convey more to his hearers than they were able to lay hold of at one sitting. He generally spoke at all meetings, and when it occurred, as it sometimes did, that someone possessed of as decided opinions as himself expressed them with an equal confidence, there was for a brief space a slight display of irascibility, which, however, immediately passed off, leaving behind no afterthought or ill-feeling. This intensity of feeling led Mr. Dunn, as a Conservative, to take a very decided stand when Gladstone fought the Midlothian campaign against the present Duke of Buccleuch, at that time Earl of Dalkeith.

I cannot close this brief and very imperfect sketch without adding something, however slight, about Malcolm Dunn as a man. Though his beautiful relations towards the members of his family are well known, it would be in this place impertinent to do more than allude to them. With regard to others it is different. He was the kindest friend, and put himself as much out of the way to do a favour to a young journeyman gardener as he would to men established in high place.

He gave liberally of his means to all deserving objects, and I am told by Mr. Todd that the only gardener who continued to send plants to his annual Orphan Bazaar was Mr. Dunn. I do not know anyone who replied quicker to a letter than he, and from the nature of the case some of these replies must have been written when most people would have been asleep in bed. I suppose everybody that has visited Dalkeith knows his hospitality, and it is a place that someone or other was continually turning up at, almost the latest visitor having been Canon Ellacombe. He was extremely simple in his tastes, always wore clothes of the same cut and colour, and, if I am not mistaken, he had an aversion to kid gloves! Though a bachelor, Mr. Dunn was fond of family life, and enjoyed a romp with children. Few will mourn his loss more than the women of the households he visited, his deference to women being very great. He was for a long number of years an elder in Dalkeith Church.

The obsequies took place on Saturday afternoon, the remains being laid in Dalkeith Cemetery. A large number of gardeners and others were present, but owing to the awkwardness of the day, and the short time people had to make ready, not a few must have been debarred the mournful satisfaction of paying their last respects to the dead. The remains were contained in an oak coffin, on which was a brass plate, inscribed with the simple words—"MALCOLM DUNN. Died 11th May, 1899. Aged 61 years."

Some lovely floral tributes covered the coffin, but nothing so lovely or so touching on so sad an occasion as the orchard garden on the bank of the Esk, glorious in its display of flowering Pear trees and Damson Plums.—R. P. BROTHERSTON.

BRITISH Horticulture has sustained a great loss by the death of Malcolm Dunn of Dalkeith. Gardeners in all parts of the United Kingdom will hear with keen regret that this skilful, energetic, and genial Scotsman has gone over to the great majority. Devoted to his calling, and eager to

advance its interests in every legitimate way, he was to the fore in all worthy projects, conferences, exhibitions, experiments, and charities; all claimed his attention, his aid, and his energy. Well might Mr. William Carmichael say, in a recent letter, "Mr. Dunn is a most useful man."

Many years have elapsed since I first made the acquaintance of Mr. Dunn, and upon the subject which was nearest to his heart—hardy fruit culture—we have corresponded frequently. Within the past few weeks I had an interesting letter from him, partly in reply to some questions I had addressed to him on Strawberry culture in Scotland. It so well indicates the kindly appreciative character of the man, and the bent of his mind as a horticulturist, that I have transcribed it.

"Please to accept my best thanks for the copy you have kindly sent me of your excellent paper on 'Orchards.' I have just read it through this evening, and find it full of the latest and best information on the subject. It is seldom so much sound advice is found in so small a space. I trust you receive encouragement to carry on your good work among hardy fruits. Strawberries for market are grown to a considerable extent in this district (the Lothians), chiefly around Dalkeith, Prestonpans, and East Linton, but the supply seldom goes further afield than Edinburgh and the district. The great centres of Strawberry growing are in Clydesdale, near Lanark, in the Blairgowrie district of Perthshire, and in the lower Dee and Don districts in Aberdeenshire. There is no good work that can be relied upon, but a lot of desultory writing and rough (often very rough) statistics have appeared in local papers. The history of the Strawberry enterprise in Scotland requires to be written by a person familiar with what he is looking at and recording. As you know, a lot of salt has to be taken with the statements of interested parties and those who give information so freely about matters on which they are ignorant. Artificial manures are not popular among the Strawberry growers, who use little else than 'farmyard' when they can get it. Fertilisers of all kinds have been tried, and generally condemned for one reason or another. On light soils they are said to burn the plants, and on heavy to make them grow foliage, but no fruit. My own experience with artificials is they are useful when you have abundance of moisture to apply with them on light soils; and on strong, marly soil, in which the Strawberry delights, they are of little use, and may do harm on a three-year course. I do not include bones in artificials; they are good but costly for a Strawberry crop.—With best regards, I am yours faithfully, MALCOLM DUNN."

His letters were always brimful of information or suggestions, and the foregoing is given because it must have been one of the last penned by our friend, and because it leaves a task as a legacy to some able horticulturist in Scotland, which I venture to hope will be carried into execution—namely, a record of Strawberry culture in the North.—R. LEWIS CASTLE.

ROYAL HORTICULTURAL SOCIETY.

DRILL HALL—MAY 16TH.

THE display at the Drill Hall, on Tuesday, was a most interesting one, and was decidedly superior to what was expected by many growers, who were of the opinion that the forthcoming Temple Show would prejudice it. This, to a certain extent, proved to be the case, as Orchids were not numerous; but the exhibits brought for the inspection of the Floral Committee were both extensive and diversified. Fruits and vegetables were not very largely represented.

FRUIT COMMITTEE.—Present: P. Crowley, Esq. (in the chair); with the Rev. W. Wilks, and Messrs J. Cheal, W. Poupert, A. F. Barron, A. H. Pearson, J. Wright, A. Dean, S. Mortimer, J. W. Bates, G. Wythes, F. Q. Lane, H. Balderson, J. Smith, G. Miles, G. Norman, R. Fife, and M. Gleeson.

THE LATE MR. MALCOLM DUNN.—Immediately after the reading of the minutes of the last meeting the Rev. W. Wilks rose, all the members present uncovering, and spoke in terms of the deepest regret of the death of one of the members of the Committee, Mr. Malcolm Dunn. The rev. gentleman said the loss of such an active energetic helper to the advancement of horticulture in Scotland must be most keenly felt; while his advice and assistance so freely rendered in movements in which the south was immediately interested were warmly appreciated, and the death of their friend was sincerely deplored. Mr. Wilks concluded by proposing that the following resolution be entered on the minutes. The proposal was seconded by Mr. J. Wright, and passed by the silent assent of the whole of the members. "The Fruit Committee of the R.H.S. have heard with great regret of the sudden death of Mr. M. Dunn, for many years a member of this Committee. Whilst recording the great loss they themselves feel, they also desire to express their deepest sympathy to the immediate friends of Mr. Dunn."

Messrs. T. Rivers & Son, Sawbridgeworth, sent a good box of Cardinal Nectarines, grown from trees in pots, started December 23rd last; the fruits were splendid and well coloured. Mr. E. Beckett, gardener to Lord Aldenham, sent an exhibit of Carter's New Forcing Turnip, which appeared to be in good form; the roots were white and crisp. A trial of this Jersey Navet type of long white Turnips is to be made at Chiswick.

Mr. J. Miller, gardener to Lord Foley, Ruxley Lodge, Esher, exhibited a large dish of Royal Sovereign Strawberry, and a dish of Apples called Keddestone Pippin, but it was decided to be the French Crab.

Mr. Alfred Bishop, Market Harborough, exhibited some excellent specimens of Monarch Strawberry, which were grown in 5-inch pots, also a good dish of Leader, which clearly demonstrated that both these varieties can be grown in pots. Mr. J. Hudson, gardener to L. de Rothschild, Esq., Acton, exhibited three pots of Cherries, Guigne d'Annonay, a black variety, fruits quite ripe.

Mr. C. J. Salter, gardener to T. B. Haywood, Esq., Woodhatch Lodge, Reigate, exhibited boxes of Tomato Hepper's Goliath, also bunches of fruit to illustrate its free-cropping qualities. The fruits were very fine, and the bunches exhibited were carrying from fifteen to twenty fruits. The same exhibitor also sent a box of Royal Sovereign Strawberry, which were unusually large and brightly coloured.

REPORT OF SUB-COMMITTEE ON MEASURES FOR FRUITS.—At the meeting of the Committee held on May 2nd a letter from the Customs authorities referring to weights and measures for fruits was read, and we now give the report of the Sub-Committee that was appointed to go into the matter. "Considering the fact that all fruits, and even varieties of the same fruit, differ considerably in their weight per bushel, we consider the quotation of imported fruit by measure altogether misleading. We are very strongly of opinion that all importations of fruit should be recorded by weight and not by measure at all. The best weight to use in this country is the ton of 2240 lbs., not the cubic ton.—(Signed) PH. CROWLEY, JAMES WALKER, WM. POUPART, GEO. MONRO, GEORGE BUNYARD."

FLORAL COMMITTEE.—Present: Chas. E. Shea, Esq. (in the chair); with Messrs. J. Fraser, C. T. Drury, H. B. May, R. Dean, J. Jennings, Jas. Hudson, J. F. McLeod, C. J. Salter, J. Fraser, Jas. Walker, J. W. Barr, J. D. Pawle, G. Gordon, E. H. Jenkins, D. B. Crane, H. J. Cutbush, E. Beckett, E. T. Cook, H. J. Jones, H. Turner, George Paul, H. Self Leonard, G. Nicholson, and Ed. Mawley.

Messrs. Jas. Veitch & Sons, Chelsea, staged a bright and attractive collection of cut flowers. The Parrot Tulips, such as Constantinople, Feu Brilliant, and Mark Graaf were very notable, as were also the species Tulipa cornuta, Gesneriana, Isabella, American Lac, Velvet Gem, and Summer Beauty. The Ixias and Tritonias were also bright. The pots of Clintonia pulchella, Schizopetalon Walkeri, Linarias, Lathenias, and Nycteria selaginoides, take us back thirty or forty years ago. The group was tastefully filled in with Adiantums and Pterises; also a group of Richardia Elliottiana in excellent condition, with plants of Pæonia arborea Elizabeth (silver Flora medal).

Messrs. R. & G. Cuthbert, Southgate, staged a collection of Azaleas consisting of Azalea mollis hybrids, also the Ghent forms, with foliage plants and Ferns. Chief amongst the Azaleas were Chevalier de Reali, Glory of Boskoop, Apellus, Ariadne, Hortulanus Witte, and Virgile (silver Flora medal). Messrs. G. Jackman & Son, Woking, contributed a display of flowering shrubs and herbaceous plants. The Trollius in variety were bright, as were also the Geums. Phlox canadensis with its pale blue flowers, and P. setacea compacta were also noteworthy; Cytisus præcox and the white form were effective. Magnolia Soulangeana was also staged in good form (bronze Banksian medal).

Mr. Chas. Turner, Slough, exhibited a group of Malmaison Carnation Princess May in capital condition edged with Maidenhair Fern (bronze Banksian medal). Messrs. Kelway, Langport, showed a collection of Pæonies in great variety. The best forms were Elizabeth, a salmon pink of good form; Jean de Reszke, a giant single white; Snowy Coles, The Mikado, Don Quixote, and Julius Cæsar (bronze Flora medal). Mr. Jas. Hudson, Gunnersbury House, exhibited some excellent plants of Heliotrope in 5 inch pots. Chameleon, a medium colour; Picciola, a dark form; and Madame Fillay, a light colour with a dwarf habit, were the varieties shown; all were first-rate forms for greenhouse decoration.

Mr. T. S. Ware, Ltd., Tottenham, exhibited a group of spring flowers, chief of which were Azalea mollis in variety, a number of late Narcissi, Geums, Primula Sieboldi in variety, Alpine Auriculas, and a collection of rock and alpine plants completed the exhibit (silver Banksian medal). Messrs. G. Paul & Son, Cheshunt, sent a large collection of herbaceous and alpine plants, such as Tiarella cordifolia, Geums in variety, Iberis gibraltarica, Iris tingitana, Phlox canadensis, and some very pretty Saxifragas. Some flowering shrubs formed a good background. The new Rambler Rose Psycho was also well displayed (silver Banksian medal).

Messrs. Barr & Sons, Covent Garden, occupied one side of the hall with an exhibit of Darwin Tulips, Narcissi, and a variety of herbaceous and alpine plants. The chief Tulips were Joseph Chamberlain, a bright crimson variety; Loveliness, a well formed rose; Hecla, a dark crimson of excellent character; Charles Dickens, Dorothy, Purple King, Glow, Cordelia, The Sultan, May Queen, and Queen of Roses in the Darwin section. The Parrot forms were in great variety, while the Primula Sieboldi in variety, Primula Auricula Celtic King, a good yellow form; Pæonies in variety, Trollius japonica fl.-plena, and Euphorbia pilosa major contributed to the display (silver Flora medal).

Mr. F. D. Godman, South Lodge, Fareham, staged some very fine specimens of hybrid Rhododendrons and Irises. The specimen of Rhododendron Aucklandi hybrid, a greenhouse form, was truly grand; the heads were huge, and pure white in colour. A red form, called Luscombe's Hybrid, a cross between Thomsoni × Fortunei, was also conspicuous. R. Nuttali and R. campylocarpum, with pale sulphur coloured flowers came from the open air. The Irises were Susiana, a fine specimen and Atrofusca (bronze Banksian medal).

Messrs. William Paul & Son, Waltham Cross, exhibited a large collection of pot Roses, also several boxes of cut flowers. The former section included excellent examples of Enchantress, a well-known Tea form, Gustav Piganeau, Emperor, La France, Violette Bouyer (in fine form),

Victor Verdier, Mad. Moreau, William Warden, Grace Darling, Corinna, and Lord Bacon. The boxes contained good examples of Sunset, La France, Souvenir du President Carnot, Princess of Wales, Clara Watson, Souvenir de Madame Eugène Verdier, Elie Morel, Empress Alexandra of Russia, Medea, Mad. Pernet Ducher, and Sappho (silver Flora medal).

Messrs. Hogg & Robertson, Dublin, staged a large collection of Darwin, Parrot, and Tulip species; the blooms were large, well coloured, and in capital condition. In the Darwin section Dr. Wagner, Donders, Theodor Jorison, Professor Balfour, Auber, Emanuel Sweerts, Mr. G. F. Wilson, Marie Edgeworth, and Laurentia were very fine. The species were well represented, and included T. Billetiana, Sunset, T. Jaune Pure, Fairy Queen, T. elegans alba, T. buenaventura, T. viridiflora, Chameleon, and Bridesmaid. The Parrot varieties were very bright and attractive, the whole comprising a very interesting exhibit (silver-gilt Flora medal).

Messrs. Wm. Cutbush & Son, Highgate, again exhibited a pretty collection of Azaleas, comprising chiefly *Azalea mollis* seedlings in good variety, also several of the double Ghent varieties, such as Iltasso, Freya, Ribiera, and Praxitele; the exhibit was well arranged with Palms and Ferns, and edged with *Isolepis gracilis* (silver Banksian medal). Mr. H. B. May, Upper Edmonton, contributed an interesting collection of thirty-six species and varieties of *Gymnogrammas*, beautifully displayed in a bed of *Isolepis*; also a yellow *Tropæolum* called Sunlight, very pure and attractive in colour, together with a few well-flowered plants of *Ivy Pelargonium Galilee*, a well-known pink form (silver Banksian medal).

Mr. G. W. Piper, Uckfield, again exhibited some excellent specimens of his new Rose Sunrise, a variety that will certainly become popular. From the Royal Gardens, Kew, came some very interesting exhibits of *Lathyrus splendens*, *Pride of California*, a beautiful form; also *Clianthus Dampieri*, with its bright flowers, and the exquisite *Amherstia nobilis*. Mr. C. Blick, gardener to Martin Smith, Esq., Hayes Common, sent a new Carnation, *Lady Hermione*, a rosy salmon form, very clear in colour, and of good type.

ORCHID COMMITTEE.—Present: Harry J. Veitch, Esq. (in the chair); with Messrs. J. O'Brien, de B. Crawshay, H. M. Pollett, F. Sander, H. J. Chapman, J. Gabriel, W. H. Young, F. J. Thorne, E. Hill, H. T. Pitt, J. Colman, A. H. Smee, T. Mason, S. Courtauld, and T. B. Haywood.

The only exhibit of Orchids that was of any particular extent was that arranged by Messrs. J. Veitch & Sons, Ltd., Chelsea. This formed one of the richest displays that has been staged in the Hall of late, and comprised quantity with excellence of quality. There were splendidly flowered plants of *Dendrobiums Bensoniæ*, *subclausum*, *thyrsiflorum* and *suavisimum*, *Odontoglossums crispum* in variety, and *odoratum*; *Lælias Latona cinnabarina*, and *purpurata*; *Lælio-Cattleyas ascania*, *Pallas*, *Wellsiana albida*, and *Zephyra*; *Cattleyas intermedia*, *Lawrenceana*, *Mendeli*, and *Mossiæ*; *Oncidiums concolor*, *sarcodes*, *phymatochilum* and *ampliatum*; *Epidendrums elegantulum*, *xanthinum*, *O'Brienianum*, and *elegantulum luteum*; *Epi-Cattleya Bowringiana*, *Trichopilia suavis alba*, *Masdevallias Heathi* and *igneæ*, *Epiphronitis Veitchi*, with *Chysis langleyensis*, *Cypripediums*, *Cymbidium*s, and others in variety. Of exceptional interest was a plant of *Cypripedium macrochilum grande*, carrying three flowers, one of which had two dorsal sepals, three long tails, and a fine pouch (silver Flora medal).

Mr. W. King, gardener to J. Colman, Esq., Gatton Park, Reigate, staged an effective though small group of Orchids, including *Odontoglossum polyanthum* Gatton Park variety, with *Cattleya Lawrenceana*, several forms of *Odontoglossum crispum*, *Lycaste Skinneri*, *Lælia purpurata*, and others (silver Banksian medal). Messrs. Hugh Low & Co., Bush Hill Park, contributed *Odontoglossum excellens enfieldense* and *O. Andersonianum giganteum*. Mr. C. J. Salter, gardener to T. B. Haywood, Esq., Woodhatch Lodge, Reigate, staged *Odontoglossum crispum Purity* and *Masdevallia Veitchi grandiflora*. de Barri Crawshay, Esq., Rosefield, Sevenoaks, was represented by one plant only, a beautifully round form of *crispum* named Raymond Crawshay. *Cattleya nobilia* Walker's variety, was sent by Mr. G. Cragg, gardener to W. C. Walker, Esq., Winchmore Hill.

Five plants only were shown by Mr. H. Ballantine, gardener to Baron Schröder, The Dell, Egham, but each of these was of superb quality. There were four *Odontoglossums*, including *Andersonianum*, The Dell variety; *triumphans*, a grand form; *Coradinei mirabile* (of exceptional merit), and *luteo-purpureum*, The Dell variety. There were also *Dendrobium sanguineum*, and two flowers of *Lælio-Cattleya Digbyana Mossiæ* (silver Flora medal). Mr. W. Murray, gardener to N. C. Cookson, Esq., Wylam-on-Tyne, showed *Phaius Phœbe*.

CERTIFICATES AND AWARDS OF MERIT.

Cerasus pseudo-Cerasus James H. Veitch (J. Veitch & Sons).—A very floriferous variety with flowers of large size, and a particularly pleasing shade of rose (first-class certificate).

Lathyrus splendens Pride of California (Royal Gardens, Kew).—A very handsome variety. The flowers are large and of a rich dark crimson maroon shade (award of merit).

Odontoglossum Coradinei mirabile (H. Ballantyne).—A remarkable form. The broad, slightly fringed petals, have a large central blotch of light chocolate, with one or two spots of similar colour. The lip and sepals are similarly marked, but the colouring extends almost over the whole surface (first-class certificate).

Odontoglossum luteo-purpureum The Dell variety (H. Ballantyne).—This is one of the richest forms we have seen of late. The form, colour, and markings are superb (award of merit).

Odontoglossum crispum Raymond Crawshay (de Barri Crawshay).—In form this is one of the most attractive varieties of *crispum* that has been shown. The colour is white clouded with rose purple, and with large chocolate blotches (award of merit).

Odontoglossum crispum Purity (C. J. Salter).—Save for the slightest rose flushings in the sepals and the yellow at the base of the lip this is pure white. It is a beautifully fringed flower (award of merit).

Odontoglossum Andersonianum giganteum (H. Low & Co.).—Both for size and colouration this is of excellence (award of merit).

Odontoglossum polyanthum, Gatton Park variety (W. King).—A very good variety of a well-known and popular type (award of merit).

Phaius Phœbe (W. Murray).—This is a hybrid resulting from a cross between *P. Sanderianus* and *P. Humbloti*. It is a superb Orchid. The sepals and petals are pale cinnamon yellow, with rose shading to white at the margin. The large open lip is rose, with deeper veins on the front lobe, with bright yellow and crimson in the throat and on the side lobes (first-class certificate).

ROYAL BOTANIC SOCIETY.

MAY 17TH.

THE summer Exhibition, held at Regent's Park, was a decided improvement on the former show. The competition was poor, but the trade exhibits made a capital exhibition.

There were two competitors in the class for a group of Orchids and foliage plants, Mr. Geo. Cragg, gardener to W. C. Walker, Esq., Winchmore Hill, was deservedly placed first with a superb group, consisting chiefly of *Cattleyas Mendeli*, *Skinneri*, and *aurea*, *Dendrobium nobile*, *Odontoglossums*, *Oncidiums*, *Cypripediums*, arranged with *Crotons*, *Palms*, *Dracænas*, and small Ferns. Mr. J. D. Clarke, gardener to L. Mond, Esq., Avenue Road, was second with a group in which the *Cattleyas*, *Lycaste Deppei*, *Miltonias*, and *Cymbidium*s were the chief features.

Mr. G. Kelf, gardener to Mrs. Abbot, South Villa, Regent's Park, came first with six specimen Palms; the plants, though small, were very clean and well grown; and Mr. Thomas Abbot, gardener to C. Newington, Esq., The Holme, Regent's Park, was placed second. Mr. G. Kelf was first for a pair of *Dracænas*. Mr. Thomas Abbot second with two plants of *D. Guilfoylei*. For twenty-four bunches of stove and greenhouse flowers, Messrs. A. W. Young & Co., Stevenage, were the only exhibitor, and received second prize.

Mr. Chas. Turner, Slough, exhibited a group of the well known *Malmaison* Carnation *Princess May*, a very free flowering red variety. Messrs. Kelway & Sons, Langport, exhibited a collection of *Pæonies*, including such varieties as Henry Irving; Elizabeth, a beautiful form; Don Quixote, a good pink, of large size; Countess Crewe, a pale flesh; Mrs. Joseph Hulton, a charming variety; Countess Cadogan, Maud Wild, Alchemist, and Julius Caesar.

Messrs. Wm. Paul & Son, Waltham Cross, had a group of pot Roses, comprising standards and trained specimens, edged with fine boxes of cut blooms. The beautiful Tea Enchantress formed the chief feature; Madame Fanny de Forest, *Violette Bouyer*, *Gustav Piganeau*, *Le France*, *Grace Darling*, and *Corinna* were very conspicuous. The boxes contained good blooms of *Clara Watson*, *Princess of Wales*, *Souvenir de Madame Eugène Verdier*, *Mlle. Thérèse Levet*, *White Lady*, and *Medea*. Messrs. R. & G. Cuthbert, Southgate, exhibited a bright group of Azaleas, consisting of some bright seedlings of *A. mollis*, and some *A. rustica*, in such varieties as *Bartholo Lazari*, *Praxitele*, *Apelius*, *Virginale*, *Aida*, and *Phœbe*, arranged in a groundwork of Ferns.

Messrs. J. Peed & Sons, Norwood, staged one of the best features of the show in a group of choice *Caladiums*; the plants were very bright and well developed, the whole arranged in a groundwork of Maidenhair Ferns, *Caladium argyrites*, and *Panicum*. The best specimens were *Charlemagne*, *Madame Marchand*, *Oriflamme*, Mrs. Harry Veitch, Mrs. J. Peed, *Reine de Danmark*, *John Laing*, *Lillie Burke*, and *Candidum*. Messrs. T. Rivers & Son, Sawbridgeworth, exhibited nine trees in pots of their new *Nectarine Cardinal*; the trees were well furnished with fruit, of a good size and exceptional colour.

Messrs. Barr & Sons, Covent Garden, made a large exhibit of Darwin Tulips, which were very effective. The varieties, *May Queen*, *Hecla*, *Joseph Chamberlain*, *Phyllis*, *Queen of Roses*, *The Sultan*, *Dorothy*, *Glow*, *Perfection*, *Loveliness*, *Queen of Brilliants*, *Carminia*, and *Petrus Hondius* were most noteworthy. The exhibit was made up of a collection of herbaceous plants in great variety.

Mr. W. Rumsey, Waltham Cross, exhibited eleven boxes of cut Roses, also a number of bunches. The best were, *Victor Verdier*, *Duchess of Albany*, *Alfred Colomb*, *Maréchal Niel*, *Ulrich Brunner*, *Niphetos*, Mrs. Rumsey, in good form, *Crimson Rambler*, and *Mad. Charles*.

Messrs. J. Laing & Sons, Forest Hill, staged a large group of flowering and foliage plants, chiefly of a decorative character, such as *Liliums*, *Ixoras*, *Azaleas*, *Palms*, *Crotons*, *Dracænas*, and Ferns.

HEREFORDSHIRE CIDER AND PERRY.—We find from some trade literature to hand from Withington, Hereford, that in consequence of the large demand for these wholesome beverages the business of Mr. John Watkins has been formed into a limited liability company, with Mr. Watkins as managing director, who will take the same active interest in this department as heretofore.

THE YOUNG GARDENERS' DOMAIN.

THE TUBEROUS-ROOTED BEGONIA.

THE tuberous Begonia is amongst the most useful plants that are grown either for pot culture or bedding during the summer months; they are plants that can be easily grown, although careful attention is required in the young stage. Propagation may be effected either by division of the old tubers or from seeds. In the latter case the seeds should be sown early in March in clean, well drained shallow pans, using a compost of equal parts of fine loam, leaf mould, peat, and sand, making it fairly firm and giving a thorough watering before sowing; when drained sow the seeds thinly over the surface, and lightly sprinkle a little silver sand over them; cover the pan with a clean piece of glass and place it in a temperature of 65° to 70° at night, 70° to 75° by day.

As soon as the seedlings appear above the surface, the glass must be removed from the seed pan, but they will require a light shading during bright days. When the seedlings are large enough to handle they should be placed in boxes about an inch apart, using a similar compost to that for the seeds. Apply water and afford the same temperature, shading when the weather is bright. When the plantlets have made a good start, and the roots have hold of the soil, remove them to a cooler house, keeping them near the glass, and when they are almost touching one another in the boxes carefully take them out with as much root attached as possible, and place in small 60-pots in a compost of equal parts of loam and leaf mould, with a small amount of sand and broken charcoal. When potted apply water, and afford a temperature of about 60° at night, also shade from bright sunshine.

The plants at this stage will grow rapidly, and when they have a fair amount of roots round the sides of the pots again remove them to a cooler place, such as a frame kept at about 50° at night. A little later the best of the plants may be again repotted into small 48's, with a compost of three parts of loam, and two parts of leaf mould, and a little sand and broken charcoal. The potting should be done fairly firm, covering the tubers about half, and it will be found necessary to tie the tallest plants to a neat stake, as they are liable to break when moved about; give the plants a good watering, but after only apply it when needed. During very hot weather when the plants are in bloom it will be necessary to lightly shade them to induce the flowers to last for a longer period.

A very suitable time for starting old tubers is about the middle of February. Lay them in boxes of cocoa-nut fibre refuse and afford a temperature of 60° to 65° at night, 65° to 70° by day. When they have made a start, they should be carefully taken out and placed into well drained pots, the compost to consist of three parts of loam, two parts of leaf mould, with a little sand and broken charcoal, after which afford them the same temperature as before. When some good roots have been formed remove to a cooler house to encourage strong, sturdy growth. Before the plants fill the pots with roots repot, a little of Thomson's Vine manure mixed with the soil for this potting being beneficial. The watering should always be carefully done, only applying it when needed, and as the plants gain vigour, a little liquid manure may be given occasionally.

For outdoor planting the beds should be deeply dug and have abundance of leaf mould added to them. The planting must be done when all fear of frost is gone, and in very hot weather if the beds are covered with some light material the flowers will last for a longer period. After the plants are cut down with the frost the tubers should be carefully lifted and placed in boxes in cocoa-nut fibre refuse to become thoroughly ripened, keeping them in a cool place.—P. R.

WELTON HOUSE GARDENS.

THE above gardens are in Yorkshire, a few miles from Brough, and they form a splendid addition to the country residence of Harrison Broadley, Esq. Mr. C. Lawton is the well-known gardener, and he has a reputation for the production of specimen plants that many might envy, and of these I propose to say a few words.

After a cordial reception we make our way to a span-roofed house of two divisions. In the first are some Orchids, all of which look the picture of health, and in the second are miscellaneous plants, chiefly for table decoration. In the stove, which has a central and side stages, are excellent specimens of Crotons of several varieties. I was much impressed by the size and colour of these plants. Notwithstanding the unfavourable weather we have experienced of late, the foliage was exceptionally large and healthy, and the colours well developed. It may be added that they were free from insect pests, which reflects credit on all concerned in their management. On the side stages were Crotons, grown on the single stem system.

The Palm house contains several Kentias, which with the other occupants of the house were of exceptionally good quality. After passing a general flowering house in which we noticed several varieties of Cycads we reached what I considered the glory of Welton House—namely, the Ericas. Here are to be found some handsome specimens of Cavendishiana and other species. Mr. Lawton considers firm potting and careful watering essential.

In a north house were Carnations of the Malmaison type, and considering the disadvantage of their position, the plants were looking wonderfully well. Another house contained some healthy Eucharises, and I must not omit to mention the Ouvirandra fenestralis (the Lattice Plant of Madagascar) as one of the most unique plants under cultivation. The leaves are simply a vegetable network, the threads of which are so open as to give the leaf the appearance of a piece of wire netting. The plant at Welton is growing in a bed of loam submerged in water, which

also covers the whole of the foliage, the temperature of the house being about 70°. Fresh rain water is added every morning with a rosed can, and the water is poured in at a distance of 2 feet above the plant, so as to carry with it the atmospheric elements which are essential.

We observed heavy crops of Cucumbers, while Melons were swelling excellently. Peaches and Vines were full of promise, and will eventually supply abundance of fruits. Strawberries were fine, the variety being Royal Sovereign, of which several plants were bearing from twelve to fifteen berries.

Adjoining the mansion is a spacious conservatory with specimens of Camellias, Tree Ferns, Dracenas, and Araucarias, and having the roof effectively covered with creepers and Roses. A word of thanks must be accorded to Mr. Lawton for the cultural hints he so readily imparted, and which will be both interesting and beneficial to my companions and myself.—J. F. D., Yorks.

[Our correspondent in his venture in describing Welton House Gardens has not been able to do them justice, and his manuscript has had to undergo a considerable amount of revision. Practical lessons or useful suggestions should be embodied in descriptive matter, and this cannot be well done within the prescribed limits of the "Y. G. D." of about 500 words.]

FRUIT FORCING.

Vines.—*Early Forced Houses.*—Where the Grapes are ripe afford fire heat only to prevent the temperature falling below 60°. Admit a little air constantly, with free ventilation when the weather is favourable. Do not allow the border to become dry, but keep it moist, and mulch with rather lumpy sweet litter, both to prevent excess of moisture and to keep the soil from cracking. A little moisture in the atmosphere is not injurious to the Grapes, and is highly beneficial to the foliage, which must be kept clean and healthy. If thrips appear recourse may be had to fumigation, repeating in the course of a few days. For red spider there does not appear any safer means of destruction than heating and sulphuring the hot-water pipes, but it must not be overdone or the vapour-fumes injuriously affect the tender-skinned Grapes, especially the white varieties.

Successional Vineries.—As little fire heat as is consistent with the steady progress of the crops should be employed, for with sun heat and abundance of atmospheric moisture more real benefit is gained in a week than in a month with the aid of fires. The Vines being in full growth the temperature may be allowed to rise to 90° or 95°, closing the house at 85°, employing fire heat only to maintain a day temperature of 70° to 75°, and to prevent it falling below 65° at night, yet 5° less will do no harm, but good when the weather is cold. These remarks apply only to Vines in full growth and swelling their crops, as those that have the Grapes approaching ripening should have a rather free circulation of air, those advanced in ripening being kept cooler and drier. Air should be admitted very early in the morning, as the sun acting powerfully on the condensed moisture formed on the foliage during the night usually causes scorching, unless air has been previously admitted.

Watering the borders must be attended to as required—not having stated times, but being guided by the soil's condition. More failures are the result of under than over-watering Vines, the borders being properly constructed and the drainage complete. Water may be required twice a week in the case of Vines restricted to narrow and shallow borders, and once a week for those that have a good run of border from the time of thinning the berries until the Grapes are changing colour, but retentive borders may only require water at fortnightly or three weeks intervals. This difference must be considered, for there is no question about a sodden soil being injurious to Grapes, and of a prolific source of shanking.

Liquid nourishment is more frequently required by loose and light soils than by compact and retentive ones. All will need top-dressings of some approved fertiliser—1, When starting the Vines; 2, when the Grapes attain to thinning size; and 3, when the berries commence ripening, supplying 4 ozs. per square yard at each dressing and washing in lightly. If more stimulation, or rather nourishment, be needed, supply the manure oftener; this is better than increasing the quantity each time and at long intervals.

Late Houses.—In most places the work now on hand is considerable in thinning the berries, and it will continue for some weeks, as in many instances the Vines are only in flower. In the latter case maintain a minimum temperature of 60° to 70°, 5° more for Muscats, shaking the Vines twice a day to distribute the pollen, which will be sufficient for all but the shy setters, and these ought to be carefully fertilised, going over the bunches judiciously with a camel-hair brush and supplying pollen where it is deficient from those that afford it freely. All the large-berried and free-setting varieties, such as Gros Colman and Gros Guillaume, should be thinned while they are in flower, and with those that are likely to have closely set berries it is advisable to thin before the flowers expand, as a practised eye can tell which flower will set by its vigour, and the removal of the weaker strengthens those left wonderfully. While the Vines are in flower, moderate moisture, with a rather

free circulation of air, is desirable; it is also inadvisable to stop or remove laterals while the Vines are in bloom, but when the berries are fairly set remove superfluous laterals and pinch as required, both to prevent overcrowding and concentrate the supplies of nourishment on the Grapes.

Planting Growing Vines.—From now to the early part of June is a good time to plant out those raised from eyes in February or March and grown in pots or turves. The roots need not be disentangled, yet turf-raised Vines are better than potted ones, as they form a straight yet fibrous root, and are not prone to descend deeply as those turned out of the pots with the ball entire. Make the soil firm about the balls or turves, give a good soaking with water at 90°, and mulch with about an inch thickness of short and rather lumpy manure. Maintain a rather humid atmosphere, and shade from bright sun until the Vines become established.

Strawberries in Pots.—The latest plants will now be commencing to swell the fruit, and as the stems are usually long the berries should be supported clear of the pots with forked sticks, pointed at the stem end and pushed into the soil, the stem of the truss resting in the fork or a little below the fruit. Thin the flowers and the fruit. The centre fruit is always the largest, and to encourage these and others of the most promising early thinning must be practised. Grand fruits are obtained in this way of such varieties as Royal Sovereign, President, Sir Joseph Paxton, Auguste Nicaise, and British Queen or Dr. Hogg. The plants should have frequent supplies of liquid manure for swelling their fruit, giving it from the time the fruit commences to swell freely until it changes colour for ripening, when clear water, and not too much of it, only the plants must not flag, will be more suitable. When ripening the atmosphere must be kept rather drier and cooler than when the fruit is swelling, and it will then be less liable to spotting, the flavour will be higher, and the aroma more pronounced.

THE KITCHEN GARDEN.

Runner Beans.—In many gardens not much is gained by sowing Runner Beans before the second week in May. Especially is this so in the case of heavy soils. Fortunately these Beans transplant readily out of pots or boxes, and those who find their earliest sown seed is germinating badly ought to sow more at once in gentle heat, and the plants, duly hardened and put out where there are gaps, will not be far behind the rest. The main crop may be sown now, and where the earliest raised rows are apt to fail in August or early in September, more seed should be sown during the second week in June. It is a mistake to crowd either the rows or plants in the rows, of this important crop. If it is intended to grow the plants without stakes, sow the seed thinly in rows 3 feet apart and crop between with either Lettuce or a row of short-topped early Potatoes. This method of culture is best adapted to the field crops. Runner Beans succeed well trained over archways and are remarkably productive when grown in isolated groups of three or more plants, with a tall stake to each.

Ridge Cucumbers.—The first week in June is early enough to put out plants of the ordinary ridge Cucumbers, unless hand-lights or cloches can be afforded for protection. Seeds, however, may be sown now on specially prepared ridges where the plants are to remain. Open a trench, running from east to west, 3 feet wide and from 1 foot to 2 feet in depth, and fill this with moderately hot prepared stable manure, covering with the soil that was thrown out, sloping it to the south, sow the seed five or six to each patch 3 feet apart, and cover with fine soil. Three plants at each station are ample, therefore thin out early where necessary. Shelter from cold winds is most desirable, and this can be afforded by rows of Runner Beans or tall-growing Peas. The plan of growing Cucumbers, with their stems in little shallow basins, facilitates watering operations, but is almost certain to end in the loss of many plants from canker of the stem. They ought to be raised rather above than below the level—a hint of which some market growers ought to take particular note.

Vegetable Marrows.—Much that has been advanced concerning ridge Cucumbers applies to Vegetable Marrows. They may be either sown where the plants are to remain, or be raised singly in 4-inch pots and put out now if they can be protected, or early in June if they are to take their chance. Plants raised early, and kept in small pots till they are drawn and have wiry stems, are not the best for planting purposes, and would be surpassed by others obtained by sowing seed singly in 4-inch pots and placing these in gentle heat now. Great heaps of manure are frequently wasted on Vegetable Marrows. On these the plants grow too rankly to be very productive, and are the first to fail from drought. Ridges, prepared as recommended for Cucumbers suit them well, and in the warmer parts of the country, or as far north as the midland counties, excellent crops are frequently obtained from plants grown on well-manured ground, and dug as for Cauliflowers or Cabbage. Seeds sown, or plants put out thinly among early Potatoes, will eventually cover most of the ground, and prove more productive than those pampered and grown on much manure.

Gourds and Pumpkins.—These are as easy to grow as Vegetable Marrows, and in far less demand. The fruit of the first named are, in many cases, quite ornamental, and prove attractive when trained over garden seats, walks, and up sunny walls. For each plant open a hole about 2 feet across, partially fill with decaying manure, and return the soil to the top of this. Raise the plants singly in small pots, and plant early in June.

Potatoes.—Early Potatoes planted in the Kentish fashion, having the soil drawn over the sets in ridges when the planting was done, were slightly damaged by frost, but the stalks escaped injury and fresh leafy growth soon began afresh. Many not moulded up in any way were blackened down to the tubers, and in some instances recovery is so

doubtful that it is advisable to break up the ground and plant afresh. Advancing crops should have a dressing of soot or other quick acting manures, sowing these over the whole of the ground between the rows, prior to finally moulding up the rows. Highly cultivated, loose rather than firm ground, invariably produces the best crops of Potatoes.

Hoeing Among Other Crops.—Much heavy rain, followed first by dry easterly winds and strong sun, with a heavy hailstorm when the change came, has left the surface of the ground in a close hard state, and unless something is done to prevent it, cracking will be the next occurrence. So hard is the ground where made fine for seed sowing that it is scarcely possible to loosen the surface by means of the flat or Dutch hoe only. But this must be done, or the progress of the crops will be unsatisfactory, and in a dry season the moisture will be all out of the ground in a surprisingly short period. First lightly break the surface with a fork, afterwards hoeing among the crops as often as necessary to keep down weeds and prevent binding afresh. A mulch of strawy manure will not be wasted on the taller-growing crops, notably Peas, Beans, and newly planted Asparagus.

THE BEE-KEEPER.

EFFECT OF THE WEATHER ON BEE-KEEPING.

It is not necessary to remind bee-keepers what an important factor the weather is in bee management. We would, however, note the difference in the weather experienced during the past six weeks and what it was a year ago. Then the majority of the stocks were very forward, and the bees were increasing at a rapid rate. There has been little difference in the rainfall; but it has been dull and cold, and unfavourable for the bees to make much headway. During the first few days of this month the sun shone brightly from an almost cloudless sky, which revived the hopes of bee-keepers. The wind, however, remained in the east the whole of the time, so that the bees were unable to fly far from their hives.

Throughout the country there is a splendid show of bloom on the early fruit trees. Cherries, both cultivated and wild, have been a mass of white, and the same may be said of Plums and Pears. These, we fear, have suffered considerably from the late spring frosts. Gooseberries and Currants are now in full blossom, but as they are protected somewhat by their foliage, they will probably not suffer so much from the frosts as the former. The Sycamores have an abundance of bloom, and although there is such a wealth of blossom in all directions on which the bees work freely and obtain both honey and pollen, they have derived little benefit from them up to the present time. In the fields, too, there is a great variety of wild flowers containing pollen, which is so necessary at this season.

Should a favourable change in the weather soon set in the bees will doubtless increase at a rapid rate. They will, however, be very backward, and it will be only those stocks that have received careful attention, as advised in previous notes, that will be in condition to derive full benefit from the early-flowering, honey-producing flowers, when the honey flow comes.

PREVENTION OF SWARMING.

Bee-keepers who do not wish to increase the number of stocks in their apiary have often a difficulty in preventing swarming. We do not know of anything more annoying to a bee-keeper when honey is coming in freely, to find that some of his best colonies have swarmed. This, however, may be almost entirely prevented if strict attention is given to them when they require it. Bees do not swarm on the impulse of the moment, they make arrangements for doing so about a week or ten days beforehand. They will not swarm until the hive is full of bees. It is important that bee-keepers should bear this fact in mind, and provide extra space as often as it is required. This is done by enlarging the brood nest, and if the body of the hive is full of frames, which are full of brood and crowded with bees, remove three or four in which the brood is most advanced, and place them directly over the brood nest with a piece of excluder zinc between. This will keep the queen in the body of the hive. The spaces from which the full combs were taken must be filled with combs or foundation.

Another plan is to place a crate of sections or shallow frames on the top; this will keep the bees employed, although honey may not be coming in freely. This should always be done in advance of their requirements. If, in addition, the hives are freely ventilated by wedging up the fronts, and shading them during bright weather, swarming may be almost entirely prevented. Bear in mind it is difficult to prevent bees swarming after queen cells are once started—
AN ENGLISH BEE-KEEPER.

B. Wells, Crawley.—*Fruit Trees*.

TO CORRESPONDENTS

All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," 8, Rose Hill Road, Wandsworth, S.W., and NOT to 12, Mitre Court Chambers, Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *nom de plumes* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Rhubarb for Early Marketing (W. B.).—Hawkes' Champagne has the advantage of colour and earliness, but it is too small in the stem for general acceptance, hence Victoria claims precedence for general marketing purposes, and after trying all the varieties we found the darker form of Victoria—there are probably several types due to soil or growth in different localities—the most profitable for either forcing or outdoor cultivation. Of course some customers prefer a red Rhubarb, and will give more for a bunch than for one of Victoria, but bulk tells vastly in favour of the grower, hence some grow both varieties, but rely mainly on Victoria. If you want an early variety grow Hawkes' Champagne.

Asparagus for Market (Idem).—There are many forms of the Giant, and when true and carefully selected all are good for general cultivation, including marketing purposes. Some growers like the Early Argentuil, but it is not always to be obtained true. By careful selection types are cultivated that possess earliness, size of heads, and abundance of produce.

Sulphate of Potash Dissolving (W. T.).—The sulphate very often deliquesces in moist air, though this may appear quite dry. We do not know of any other reason, though possibly it may be due to some defect of the article, and of which we can form no opinion, but we have found it desirable to use the sulphate soon after receiving it, or mix with some absorbing substance, such as fishmeal.

Manure for Growing Exhibition Onions (Idem).—The best we know of is apply a dressing of kainit in the autumn, 3½ lbs. per rod, then, or very early (not late) in spring, apply a dressing of very short manure, 1 cwt. per rod, with 3½ lbs. of basic slag phosphate, and half as much mineral superphosphate, harrowing or raking in. Then when the young plants are well up and beginning to grow, use finely crushed nitrate of soda, three-quarter pound per rod, and continue these applications of the nitrate about every three weeks. The method of growing large bulbs of Onions by raising the plants under glass has more than once been described in the *Journal of Horticulture*. There is no work on the subject you name, and the specimen you submitted cannot be identified, being spoiled through the delay arising through wrong direction. The correct address is published every week at the head of this ("Correspondents'") page and the leading article.

Leaves from Fumigated Peach House (Sylvia).—The leaves are simply blistered by the use of the tobacco paper, which, however, is of excellent quality, and not likely, except in overdose and misapplication, to injure the foliage of Nectarine and Peach trees. It requires knowledge and judgment to use tobacco paper and nicotine essence by fumigation and vaporisation when the foliage is tender. The trees have different degrees of susceptibility to injury, which occasions the need of great circumspection. The injury probably arises from the expansion of the air moisture by the heat given off from the burning tobacco paper, causing the condensation of moisture on the surface of the leaves, especially on their thinner and cooler parts, near the edges of the foliage, and thus scalds their tissues. We have noted every phase of both fumigation and vaporisation, and consider both extremely dangerous in the case of tender foliage. With the foliage harder and the moisture of the house reduced to a minimum, no harm results if careful not to give an overdose. For the reasons given we consider it advisable not to fumigate, but instead steep the tobacco paper in water or even nicotine essence treated similarly, and syringe the trees with the decoction or solution, using 2 ozs. of softsoap to each gallon.

Mice Eating Seeds (C. C.).—Had your Beans and Peas been moistened with petroleum, and forthwith dusted with red lead, sowing immediately, and further, if a covering of sharp ashes, half an inch thick and a foot or so wide, had been spread on the surface of the soil over the rows, a slight sprinkling of petroleum being given occasionally, we suspect the culprits would have gone elsewhere for vegetable food.

Planting a Vine (Idem).—If you can find a good Vine well established in a pot, and you can secure it with unbroken growths up to 6 inches or more long, the Vine will grow if planted with the ball of soil practically intact, only removing the crocks and loose surface soil; in fact proceeding exactly as if shifting into a larger pot, and packing a turfy compost firmly round the mass of roots. The soil in the pot must not be dry, or very wet, when planting. Your other question cannot be answered this week.

Galeopsis dubia (L. Row).—The flower sent represents *Galeopsis dubia*, and as it will probably be unknown to many of our readers, we give an illustration (fig. 92) of the flowers and foliage. It is a member of the Labiata family, and is an example of a native plant succeeding well under cultivation. It is an annual, requiring a somewhat sandy soil, in which it grows freely and flowers during the late spring and

FIG. 92.—GALEOPSIS DUBIA.

summer. The flowers are yellow, varying slightly in the depth of colour, sometimes very pale or rarely white, while forms have also been observed with a purplish tinge. They are large and clustered at the apex of the stems, the leaves being sharply cut at the margins. This *Galeopsis* is widely distributed in Europe, but is somewhat rare in England. It is readily raised from seeds, which are produced freely.

Destroying Slugs (J. A.).—The pests are very troublesome in some cases, and become almost proof against dressings of quicklime and soot, though we find these excellent, especially when used just after dark, so as to fall on the molluscs, the lime being quick and the soot fresh. Some prepare lime water, a peck of quicklime being placed in a tub, slaked, and 30 gallons of water poured on, stirred well and then allowed to settle, using the clear lime water after three or four days. It is applied in the evening with a fine rose watering can when the slugs are out feeding, and not many safely escape the effects of the lime water. Another good plan is to use finely crushed nitrate of soda, 2 lbs. per rod, preferably before sowing or planting, or if cropped use when the plants are dry, and keep from their hearts. Of traps we have found fresh brewers' grains very serviceable, placing in small heaps on slates, and attending to them after dark with a lantern. Of all traps the mixing of treacle with bran, the syrup being thinned with a little rum so as to admit of ready sprinkling on the bran, appears the most attractive.

Insect on Apple Shoots (*E. E. and S.*).—The small greenish yellow insects are the Apple sucker, *Psylla mali*, which, by abstracting the juices of the foliage, impairs the vitality of the trees. There does not appear to be any American blight—certainly not on the twigs sent. The best wash is petroleum emulsion—the soluble petroleum advertised—diluted with twenty-five parts of water.

Marguerite Leaf Miner and Coal Tar (*G. A.*).—Boil half a gallon of coal tar in a gallon of water for fifteen minutes, or till the tar and water are perfectly blended, let it cool, then add to it 50 gallons of water. This tar water so made is lightly distributed in fine spray over the leaves, and also over the stages, shelves, walls, sashes—anything and everything near the plants.

County Councils and Gardeners' Improvement Associations (*W. E. Groves*).—What you request would, as you say, amount to a "tall order" if we were to cite from "the Acts of Parliament which govern the whole business" of grants such as you have in view. There is, however, no occasion to do anything of the kind. County Councils have the right to apply the funds placed at their disposal within the terms of the Technical Instruction Act of 1889 to various purposes of education, including horticulture. They can and do make grants to borough and urban authorities, and in such cases these authorities can appropriate the amounts as they wish, but if their application is not approved by the County Council, this body has the power to decline to renew the grant. Also we think grants are made in some instances to the officials of gardeners' improvement associations for such specific purposes as are approved by the county authorities. You had better place your case and requirements before the Organising Secretary of the Technical Education Committee of the County Council, from which you desire aid, and ask his advice as to further procedure.

Juniper Branch Infested with Fungus (*C. C. E.*).—The branch is infested by the fungus called "cedar apples," a name given to the outgrowths of the final stage of the Pear-rust fungus, which occurs on *Juniperus sabina*, *J. virginiana*, *J. phoenicea*, *J. oxycedrus*, and *Pinus halepensis*; when fresh it is abruptly conical or cylindrical, golden-yellow, and very conspicuous. This form is *Gymnosporangium Sabinae*, syn. *G. fuscum*, and from occurring on Junipers, the wood of which is termed cedar in commerce, popularly called "cedar apples." It gives rise to Pear-rust, *Roestelia cancellata*, short-necked, bottle-like bodies, situated together on orange-yellow, cushion-like, swollen blotches on Pear leaves, though there may be the one fungus without the other. On the Juniper we do not know of any remedy beyond removing and burning the diseased parts, and this as soon as detected, so that by destroying the cedar apples containing the teliospores, the disease cannot spread. It has been advised to spray Pear trees with Bordeaux mixture to prevent the Pear rust, but it does not usually do much harm in this country, and we have found removing the affected leaves and burning them the best procedure.

Black Alicante Vine Shoots Terminated by Bunches (*M. K.*).—It is not unusual for this variety to produce the bunches at the end of the growths to some extent, and these will perfect the Grapes, especially if a lateral from the topmost leaf be allowed to grow to the extent of three or four leaves, and thus carry the foliage beyond the bunch, though originated from below it. There does not appear any remedy in long pruning, but the reverse, for, as you say, the shoots otherwise grow very coarse and split into a number of shoots and tendrils at about the fifth joint. The point is to get the wood well ripened, then close pruning gives good results, especially if the Vines are well supplied with potash so as to cause free growth, also using a little sulphate of iron. The following mixture should help the Vines:—Bone superphosphate, dry and crumbling, five parts; sulphate of potash, three parts; sulphate of magnesia, one part; and sulphate of iron, one part; all finely powdered and mixed, using 4 ozs. per square yard, and pointing in lightly, as the roots are not near the surface. The exudation of moisture shows the Vines to be vigorous. The house should be ventilated a little constantly and air admitted freely in the daytime, especially early, without causing a draught or lowering the temperature. Encourage more foliage on the Alicante, and then it may grow out of the stuntedness.

Apple Shoot and Leaves (*W. E. H.*).—There are no caterpillars of the red bud moth (*Tmetocera ocellana*) in the leaves—at least, we failed to discover any, though the leaves were rolled up in some instances. We found, however, a far worse pest—the bud shoot tunneller moth or Apple twig moth (*Laverna vinolentella*), which eats the "heart" out of the twig, so that the young shoot or blossom bud becomes sere, and has a withered appearance. The caterpillar was very active, though only about a quarter of an inch in length, with a black head and tail, also dark segment next the head, and six black legs. We have known the animal half a century on Crab and Crab Apple trees, a closely allied species, *L. atra*, infesting "haws." We know of no remedy or even preventive but to remove the affected twigs, cutting them clean off about an inch below the point of attack and burning them. A grower, who sprays with Paris green in spring and with Bordeaux mixture in autumn against canker fungus, has not got any bud moths, though there are plenty in the old orchards and woods near his plantation. The red or crimson discoloration on the leaves that are stunted and distorted is the work of a fungus, Apple leaf blister (*Ascomyces bullatus*), very common in some localities, especially gravelly or chalky soils. Spray with Bordeaux mixture, and add Paris green for caterpillars.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a

flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*Debden*).—*Miltoia flavescens*, see page 402. (*H. W.*)—The variety of *Laelia purpurata*, of which you send a flower, is very good, particularly the rich dark lip; the petals lay back rather too much for a really excellent flower, but this is to a certain extent governed by the constitution of the plant. (*D. H.*)—1, *Abies Douglasi*; 2, *Ceanothus dentatus*; 3, *Prunus Padus*. (*Mayfield*).—Winter Majetin. (*Young Gardener*).—1, specimen insufficient, a *Berberis*, possibly *dulcis*; 2, *Pulmonaria officinalis*; 3, *Davallia canariensis*; 4, *Erica depressa*; 5, *Cytisus racemosus*; 8, *Ophiophogon jaburan variegatum*.

Bedding out plants in variety from 3s. doz.

MANURES FOR SWEDES.

As the time of drilling Swedes is now rapidly approaching, it would seem to be opportune to consider what assistance we shall give to the soil in order to produce the most remunerative crop.

Before we consider the effect of manures we must lay considerable stress on the fact that the preparation of a good tilth has more to do with the production of a crop of Turnips than has the choice of manures. Then, again, we are not going to take into account any

but the present crop of roots. If we considered the whole course, Swedes, Barley, seeds, and Wheat, we should probably have to vote for bonedust, or half-inch bones, with a little admixture of superphosphate, for the immediate benefit of the roots. But we must adhere to our text, and consider manures for Swedes only.

It used to be an axiom in the Midlands that Swedes could not be grown without farmyard manure. That is an exploded idea. We ourselves have grown them well without, and we believe that when Messrs. Machin so easily won the farm prizes offered by the Royal Agricultural Society to Lincoln and Notts a few years ago, the exceedingly fine roots which were such a marked feature of their farming, were grown almost, if not altogether, with artificials alone.

So many experiments have been tried at Woburn and elsewhere with such unvarying results, that it may seem almost useless to chronicle any more tests, but when further information is available, and it clearly endorses the correctness of the previous records, there seems to be justifiable reason for its publication. At any rate, if the truth is not continuously being preached, we very soon find someone ready to teach error, and if the conclusions of the scientific world do not suit the trade and pocket of the manure merchants, they will soon be telling the farmers that experiments may be very interesting, but are of little practical value.

The Lancashire County Council conducted trials of artificial manures for growing Swedes on seven different farms in 1898. The soils were various; peaty, loam, clay, gravel, and sand, limestone being the only formation of any importance not included. Though there were slight differences in the results, as a whole they were wonderfully uniform, and therefore very conclusive in their evidence.

The first and most important point which we notice is that the application of artificials along with farmyard manure produces little return compared with those obtained from the use of the same kinds and qualities of artificials used alone, and that more care is necessary in selecting artificials to use in combination with muck than to use alone.

We find, for example, that on the average of the different soils the weight of crop grown without the aid of any manure, natural or artificial, is 9 tons 11 cwt. 3 qrs., that grown with twelve loads of good yard manure per acre is 18 tons 15 cwt. 1 qr., whilst the different artificials added raised the crop in every case to as much as 21 tons, but in some cases to nearly 25 tons, so that the artificials only increased the crop by from $2\frac{1}{4}$ to $6\frac{1}{4}$ tons per acre more than the manure had done alone. The true conclusion to be drawn from this, and every farmer of any experience will endorse it, that there is a limit to the amount of increase to be produced by plants, and that limit is found much earlier than theorists would imagine, in fact, the lucrative limit is very soon arrived at.

For instance, in these experiments we are considering the increase produced by artificials was about 100 per cent, or practically the same as by twelve loads of manure, whereas where the two were put on together, the produce was only increased by a further 25 per cent., thus plainly showing that the limit of production was being approached, and that it was not merely an absence of any one constituent which made the others inoperative.

One apparently astonishing result was that the artificial mixtures containing nitrogen gave in every case a better return by themselves than when used in conjunction with farmyard manure, whereas superphosphate and basic slag produced a greater weight when used with farmyard manure than either by themselves alone, or by farmyard manure alone. Mixtures containing nitrogen, whether in the form of nitrate of soda or of sulphate of ammonia and including seven different mixtures, in every case gave a higher return when used alone than when used with twelve loads of muck. How can this be? We cannot account for it except by the presence of the anti-nitric bacterium in the manure, which acts on and dissipates the ammonia contained in the artificials, thus actually reducing the crop instead of increasing it.

The first lesson we learn from these trials is a very old and well-worn one—viz., that with muck for Turnips nothing in the way of

ammonia should be used, but that superphosphate and basic slag may be usefully employed with it.

The second, that to grow Swedes without farmyard manure the artificials used should contain, in addition to considerable quantities of phosphate, a certain percentage of nitrogen and potash.

The third, that the use of potash and nitrogen along with farmyard manure is not only unnecessary, but a waste of money.

The fourth, that nitrate of soda, or its equivalent in the shape of sulphate of ammonia, has yielded a marked increase where muck has not been used.

And the fifth, that the use of 5 cwt. of superphosphate, 1 cwt. nitrate of soda, and 1 cwt. muriate of potash has yielded not only the largest, but the most profitable returns.

One very interesting feature of the experiments was the use of a mixture containing two parts each of superphosphate, pure dissolved bone, bone flour, and bone meal, and one part each of sulphate of ammonia and sulphate of potash. This was used in three different quantities—5 cwt., 7 cwt., and 9 cwt. per acre—and with a curious result: for the medium dressing, 7 cwt. produced the best crop, whether used alone or in conjunction with yard manure.

WORK ON THE HOME FARM.

We had a few very fine days with drying winds, and though the nights were a little frosty, the land was beginning to work well; later we had heavy rain, and if the temperature will only rise to a point more suitable to the season, crops and pastures will soon be making better growth. But the truth is, that we have had quite enough rain, and sunshine without frost is required now. A dry May is good for grain crops almost everywhere.

Wheat varies very much, some fields looking thin and patchy, and much gone off from winter promise. The hoe must be kept closely at work here, and if the soil be light a rolling will do more good than harm but there is nothing beats the hoe for improving thin crops. Earthing-up does Wheat as much good as it does to Potatoes, for it seems to encourage it to tiller, and so fill up the gaps.

Top-dressing may still be used, but the land must be in very poor condition if it will pay on thin Wheat. In any case be careful not to apply too heavy a dressing, especially of nitrate of soda. For late dressings 80 lbs. per acre is ample. It may be mixed with salt, and sown by hand; but as good sowers are now very scarce, and the work should be well done, the use of a manure distributor is recommended. The Strawsoniser is excellent for applying small top-dressings.

Do not move Turnip land more than necessary now before sowing. It had better not be ploughed at all as ploughed wet; but if it is thought to be advisable to plough again, be sure to roll it as soon afterwards as the roll will work well, then harrow and roll again if there are any rough pieces still to break. If the land has been well worked in autumn and winter, we should prefer to let it lie until a day or two before sowing time, and then use the spring tooth cultivator and chisel harrows to quickly work a good tilth on the surface for the Turnips, leaving the soil below an unknown quantity.

Mangolds are coming up slowly, and will not do well without more sun. Carrots are coming through, and so are a few weeds. These must be closely watched and exterminated, or there will not be many Carrots.

It is too cold yet to clip the ewes, but they are washed and ready for the shears when the weather will permit.

7th.—Brilliant throughout.

8th.—Brilliant early; cloudy for an hour or two at midday, and then bright again, but slight showers after 7 P.M.

9th.—Overcast almost throughout, but faint sunshine at times.

10th.—Fair, but sunless morning; smoke fog at noon; sunny after

11th.—Overcast early, faint sun from 11 A.M.

12th.—Fair, but generally dull, though sunshine at times.

13th.—Generally overcast, but a little sunshine in morning.

Temperature still near the average, and rain very deficient.—G. J. SYMONS.

BARR'S PURE GRASS SEEDS

For Lawns, Tennis Courts & Cricket Grounds.

The following mixtures are composed of PURE GRASS SEEDS only, which have been thoroughly cleaned and carefully mixed. They cannot fail to give the most satisfactory results.

We sell the seed by weight, which is the only correct method of estimating quantity needed for a given space.

BARR'S "THAMES EMBANKMENT" GRASS SEEDS for Parks.—A special mixture which has been found very successful in many public and private parks and squares around London and throughout the country. Per lb., 1/3; per 10lb., 10/6; per 20lb., 20/-.

BARR'S "STANDARD" GRASS SEEDS for Garden Lawns, Golf Links, Cricket Grounds, &c.—In this mixture there is a larger quantity of dwarf, fine-leaved Grasses than in Barr's "Thames Embankment." Per lb., 1/6; per 10lb., 12/6; per 20lb., 22/6.

BARR'S NEW MIXTURE OF DWARF GRASSES for producing an Extra Fine Smooth Lawn.—A special mixture of the finest-leaved and dwarfest-growing Grasses, producing an EXTRA FINE VELVETY TURF, and saving labour in not requiring frequent mowing. Per lb., 2/-; per 10lb., 18/-; per 20lb., 34/-.

Fuller particulars, with Hints on the Management of a Lawn, sent on application.

BARR'S NEW LAWN MANURE, "PHYTOBROMA." **WATSON'S LAWN SAND**, the best Weed Killer for use on Lawns. Full particulars on application.

BARR'S SEED GUIDE (free) contains a full Descriptive List of the best Vegetables and most beautiful Flowers, with many practical Hints on Culture, valuable to Gardeners, Amateurs, and Exhibitors.

No. 987.—VOL. XXXVIII., THIRD SERIES.

DAHLIAS! DAHLIAS!! Ware's UNRIVALLED COLLECTION

We are now Booking Orders for Immediate Delivery.

Special attention is drawn to the two following beautiful NEW CACTUS VARIETIES for 1899.

Early Orders are solicited as the stock is limited.

E. O. GREENING.—Purple, shaded crimson, medium sized flowers, long and twisted petals; very free flowering; 2½ to 3 feet high. 5/- each.

SYLVIA.—Silvery-lilac shaded rose, splendid shade of colour, wonderfully free blooming, a splendid flower for cutting, lasting very long when cut; flower stem long and stiff; 4 feet in height. 5/- each.

NEW CACTUS DAHLIAS, Vars. of 1898.

Including such sorts as:—ARACHNE, CAPSTAN, FALKA, ISLAND QUEEN, LAVERSTOCK BEAUTY, RUBY, &c. 2/- each.

CACTUS DAHLIAS, General Collection.

All the leading varieties. Our selection, 5/- doz.

SINGLE CACTUS DAHLIAS (New Type).

Our selection, 5/- per dozen.

DAHLIAS.—Singles, Pompons, Shows, and Fancies, in great variety. Our selection, 5/- per dozen.

BEGONIAS.

WARE'S GOLD MEDAL and 1st PRIZE STRAIN.

(If required started into growth, an intimation should be given to this effect.)

Single—Mixed, 3/- per doz.; 20/- per 100.

„ To colour, 5/- doz.; 32/- per 100.

„ Extra choice, for Conservatory or Exhibition, 9/- and 12/- per doz.; 65/- and 75/- per 100.

„ Named sorts, splendid forms and colours, from 1/6 each.

Double—Mixed, 5/- per doz.; 35/- per 100.

„ To colour, 8/- and 10/- per doz.; 60/- and 80/- 100.

„ Gems for Exhibition, 18/- and 24/- per doz.

„ To name, THE FINEST EVER OFFERED, from 36/- per doz.

DAHLIA CATALOGUE, containing Illustrations of many new sorts, and list of varieties with full descriptions, post free upon application.

N.B.—All Orders amounting to 20/- and upwards when accompanied by cash, are sent Carriage and Packing free.

THOS. S. WARE, LTD., HALE FARM NURSERIES, TOTTENHAM, LONDON.

LONDON FERN NURSERIES,

LOUGHBOROUGH JUNCTION, LONDON, S.W.—Ferns, large and small, in variety; Aralias, Grevilleas, Cyperus, Ficus, Ericas, Palms, Dracenas, Aspidistras, Hydrangeas, Pelargoniums, Fuchsias, Marguerites, Crotons, &c. Trade, send for Wholesale List. Special List for Amateurs, send for one.—J. E. SMITH.

"SUNPROOF" Shading.

An entirely new Glasshouse Shading, sold in 6d. 1lb. tins, to be washed on the glass with cold water, as if it were soap. Guaranteed to be one-half the price, and to be the only shading in a solid state ready for use without the waste of time and material in being prepared, and to be superior to any other shading. Try it for yourself, and if not entirely satisfactory your money will be returned.

S.M. TREE FASTENERS.—The cheapest and best method of fastening plants and trees to walls. Being made of pure soft lead and not fixed to the nails (like patent wall nails, which when the nails get broken the article is useless), they may be used with ordinary nails for a lifetime. Under 2d. per dozen.

S.M. CLIPS.—To be used in the place of raffia, &c., for tying all plants to stakes, &c. Fastens instantly, and is everlasting, so saves time, trouble, and expense. 1d. doz.

FLOWER GRIP HOLDERS.—The only self-making buttonhole, watertight flower-holder ever invented, and the best for show and other purposes. Price 6d.; ladies', 9d.

IVORINE PLANT LABELS of every Description, guaranteed the cheapest Imperishable Labels, and the wording legible and permanent. Samples free.

WATERPROOF INK, for writing on all kinds of Labels, whether wood or metal. The only ink to stand the outside weather. Price 7d. Bottle.

GARDENER'S FOUNTAIN PEN, filled with the water-proof ink, 1/-.

Send for Illustrated List, with samples, for further particulars and other articles of the

WEST'S PATENT GARDEN SPECIALITIES.

Gratis, "ORCHID CULTURE," per Post.

A Treatise on the Cultivation of Orchids, giving all particulars of their requirements, along with our Catalogue, &c.

THE LEEDS ORCHID COMPANY, ROUNDHAY, LEEDS.

GREENHOUSES from £3 5/-; **VINERIES**, **CONSERVATORIES**, **FRAMES**, **SUMMER HOUSES**, &c. Illustrated List Free. Makers to H.M. THE QUEEN and H.R.H. THE PRINCE OF WALES.

TREES AT KEW.

DECIDUOUS trees and shrubs constitute the chief portion of the attractive features in a good arboretum during May, and certainly no better season can be selected for a visit to this important department at the Royal Gardens, Kew. Even those who are not specially interested in the admirable collections of rare and beautiful trees there exhibited, can appreciate the wealth of floral beauty, the graceful habit of growth, or the fresh, delicate, and varied foliage tints on every side. With strict regard to the scientific objects of the establishment, an observer cannot fail to notice that considerable taste has been displayed in the grouping of the trees in many parts, and the system of "massing," to produce telling effects, is exactly adapted for any park or garden where space permits.

The advantages of such a method are—First, that a group can be formed of young trees or shrubs, and individual defects are lost in the mass; secondly, there are many species which present a rather insignificant appearance singly, whereas in bulk they have a good appearance; and thirdly, if individuals are observed to be developing in a way that is likely to render them more valuable as single specimens they can be removed and their places filled with others. The beauty of a finely proportioned healthy specimen tree must be fully appreciated by all, and at Kew the respective characteristics of the same species can in many cases be studied both in groups and as single specimens.

To write about the improvements effected in our national garden within recent years would be only recording what has been repeatedly noted before, but the arboretum has shared in the advance, and less is heard about the work. In 1768 it is officially stated there were 488 species and varieties of hardy trees and shrubs, and it is now said there are over 3000 in the collection. But it has not been merely in the increase of numbers that improvement is manifest, the nomenclature has been closely examined, a most formidable task, with the result that some approach to order has been secured and

embodied in the useful handlists now available to the public. The confusion that has long existed in private gardens and nurseries with regard to deciduous trees and shrubs has been deplorable, and it is only in such an establishment as Kew that the work of comparison and determination can be satisfactorily carried out. I understood from Mr. G. Nicholson, V.M.H., the Curator, that the lists are undergoing a still further revision, and as he has made a close study of trees for so many years Sir William Dyer must find his assistance invaluable.

At the present time the chief floral attractions are afforded by the numerous members of the great Rose family included in the genera *Pyrus* and *Prunus*, with the latter being incorporated the species commonly ranked under *Cerasus* in gardens and nurseries. Amongst the forms of *Pyrus* there are many worthy of notice, but only a few can be mentioned here. The object in the arboretum is to show the principal wild types either considered as species or varieties, with a few of garden origin which possess some special botanical value as resulting from intercrossing or distinctness of characters. For this reason, presumably, the ordinary garden varieties of Apples and Pears are excluded, and yet a few large beds might be devoted to some varieties with advantage, at least that is my opinion, and it is shared by others. No one would expect to see an orchard formed at Kew, but when the ornamental powers of hardy flowering trees are being displayed, there are certain varieties, especially among Apples, which might well be included, as they may be placed amongst the handsomest trees at our disposal, though this is by no means recognised as it should be. I have had the satisfaction of forming such a plantation, and I should like to see others of a similar design, for there are varieties amongst the Apples which for size, colour, and abundance of flowers cannot be surpassed by any trees adapted for this climate.
